# Table of Contents

|  |         |
|--|---------|
| Preface .....  | xxxii   |
| Preface to the Csound Manual .....                     | xxxii   |
| History of the Canonical Csound Reference Manual ..... | xxxiii  |
| Copyright Notice .....                                 | xxxiv   |
| Getting Started with Csound .....                      | xxxvi   |
| What's new in Csound 6.06 .....                        | xxxviii |
| I. Overview .....                                      | 1       |
| Introduction .....                                     | 4       |
| The Csound Command .....                               | 5       |
| Order of Precedence .....                              | 5       |
| Description of the command syntax .....                | 5       |
| Csound command line .....                              | 7       |
| Command-line Flags (by Category) .....                 | 17      |
| Csound Environment Variables .....                     | 28      |
| Unified File Format for Orchestras and Scores .....    | 31      |
| Description .....                                      | 31      |
| Example .....  | 33      |
| Command Line Parameter File (.csoundrc) .....          | 34      |
| Score File Preprocessing .....                         | 34      |
| The Extract Feature .....                              | 34      |
| Independent Pre-Processing with Scort .....            | 35      |
| Using Csound .....                                     | 36      |
| Csound's Console Output .....                          | 36      |
| How Csound works .....                                 | 37      |
| Amplitude values in Csound .....                       | 38      |
| Real-Time Audio .....                                  | 40      |
| Realtime I/O on Linux .....                            | 40      |
| Windows .....  | 48      |
| Mac OSX .....  | 48      |
| Optimizing Audio I/O Latency .....                     | 49      |
| Configuring .....                                      | 51      |
| Syntax of the Orchestra .....                          | 52      |
| Orchestra Header Statements .....                      | 53      |
| Instrument and Opcode Block Statements .....           | 53      |
| Ordinary Statements .....                              | 54      |
| Types, Constants and Variables .....                   | 54      |
| Variable Initialization .....                          | 55      |
| Expressions .....                                      | 55      |
| Directories and Files .....                            | 56      |
| Nomenclature .....                                     | 56      |
| Macros .....   | 57      |
| Named Instruments .....                                | 57      |
| User Defined Opcodes (UDO) .....                       | 60      |
| K-Rate Vectors .....                                   | 60      |
| Function Syntax in Csound6 .....                       | 61      |
| The Standard Numeric Score .....                       | 62      |
| Preprocessing of Standard Scores .....                 | 62      |
| Carry .....  | 62      |
| Tempo .....  | 63      |
| Sort .....   | 63      |
| Score Statements .....                                 | 64      |
| Next-P and Previous-P Symbols .....                    | 64      |
| Ramping .....  | 65      |

---

|  |     |
|--|-----|
| Score Macros .....                               | 66  |
| Multiple File Score .....                        | 68  |
| Evaluation of Expressions .....                  | 69  |
| Strings in p-fields .....                        | 70  |
| Front Ends .....                                 | 72  |
| CsoundAC .....                                   | 73  |
| CsoundVST .....                                  | 74  |
| Building Csound .....                            | 77  |
| Csound Links .....                               | 78  |
| II. Opcodes Overview .....                       | 79  |
| Signal Generators .....                          | 83  |
| Additive Synthesis/Resynthesis .....             | 83  |
| Basic Oscillators .....                          | 83  |
| Dynamic Spectrum Oscillators .....               | 83  |
| FM Synthesis .....                               | 84  |
| Granular Synthesis .....                         | 84  |
| Hyper Vectorial Synthesis .....                  | 85  |
| Linear and Exponential Generators .....          | 85  |
| Envelope Generators .....                        | 86  |
| Models and Emulations .....                      | 86  |
| Phasors .....                                    | 87  |
| Random (Noise) Generators .....                  | 88  |
| Sample Playback .....                            | 89  |
| Soundfonts .....                                 | 90  |
| Scanned Synthesis .....                          | 91  |
| Table Access .....                               | 92  |
| Wave Terrain Synthesis .....                     | 93  |
| Waveguide Physical Modeling .....                | 93  |
| Signal Input and Output .....                    | 95  |
| File Input and Output .....                      | 95  |
| Signal Input .....                               | 95  |
| Signal Output .....                              | 95  |
| Software Bus .....                               | 96  |
| Printing and Display .....                       | 96  |
| Sound File Queries .....                         | 96  |
| Signal Modifiers .....                           | 98  |
| Amplitude Modifiers and Dynamic processing ..... | 98  |
| Convolution and Morphing .....                   | 98  |
| Delay .....                                      | 98  |
| Panning and Spatialization .....                 | 99  |
| Reverberation .....                              | 101 |
| Sample Level Operators .....                     | 101 |
| Signal Limiters .....                            | 102 |
| Special Effects .....                            | 102 |
| Standard Filters .....                           | 102 |
| Specialized Filters .....                        | 104 |
| Waveguides .....                                 | 104 |
| Waveshaping and Phase Distortion .....           | 104 |
| Instrument Control .....                         | 106 |
| Clock Control .....                              | 106 |
| Conditional Values .....                         | 106 |
| Duration Control Statements .....                | 106 |
| FLTK Widgets and GUI controllers .....           | 106 |
| FLTK Containers .....                            | 109 |
| FLTK Valuators .....                             | 109 |
| Other FLTK Widgets .....                         | 110 |
| Modifying FLTK Widget Appearance .....           | 110 |
| General FLTK Widget-related Opcodes .....        | 111 |

|   |     |
|---|-----|
| Instrument Invocation .....                                 | 111 |
| Program Flow Control .....                                  | 112 |
| Real-time Performance Control .....                         | 113 |
| Initialization and Reinitialization .....                   | 113 |
| Sensing and Control .....                                   | 114 |
| Stacks .....  | 115 |
| Sub-instrument Control .....                                | 116 |
| Time Reading .....  | 116 |
| Function Table Control .....                                | 117 |
| Table Queries .....   | 117 |
| Read/Write Operations .....                                 | 117 |
| Table Reading with Dynamic Selection .....                  | 118 |
| Mathematical Operations .....                               | 119 |
| Amplitude Converters .....                                  | 119 |
| Arithmetic and Logic Operations .....                       | 119 |
| Comparators and Accumulators .....                          | 119 |
| Mathematical Functions .....                                | 120 |
| Opcode Equivalents of Functions .....                       | 120 |

## Preface to the Csound Manual

Barry Vercoe, MIT Media Lab

Realizing music by digital computer involves synthesizing audio signals with discrete points or samples representative of continuous waveforms. There are many ways to do this, each affording a different manner of control. Direct synthesis generates waveforms by sampling a stored function representing a single cycle; additive synthesis generates the many partials of a complex tone, each with its own loudness envelope; subtractive synthesis begins with a complex tone and filters it. Non-linear synthesis uses frequency modulation and waveshaping to give simple signals complex characteristics, while sampling and storage of a natural sound allows it to be used at will.

Since comprehensive moment-by-moment specification of sound can be tedious, control is gained in two ways: 1) from the instruments in an orchestra, and 2) from the events within a score. An orchestra is really a computer program that can produce sound, while a score is a body of data which that program can react to. Whether a rise-time characteristic is a fixed constant in an instrument, or a variable of each note in the score, depends on how the user wants to control it.

The instruments in a Csound orchestra (see *Syntax of the Orchestra*) are defined in a simple syntax that invokes complex audio processing routines. A score (see *The Standard Numeric Score*) passed to this orchestra contains numerically coded pitch and control information, in standard numeric score format. Although many users are content with this format, higher level score processing languages are often convenient.

The programs making up the Csound system have a long history of development, beginning with the Music 4 program written at Bell Telephone Laboratories in the early 1960's by Max Mathews. That initiated the stored table concept and much of the terminology that has since enabled computer music researchers to communicate. Valuable additions were made at Princeton by the late Godfrey Winham in Music 4B; my own Music 360 (1968) was very indebted to his work. With Music 11 (1973) I took a different tack: the two distinct networks of control and audio signal processing stemmed from my intensive involvement in the preceding years in hardware synthesizer concepts and design. This division has been retained in Csound.

Because it is written entirely in C, Csound is easily installed on any machine running Unix or C. At MIT it runs on VAX/DECstations under Ultrix 4.2, on SUNs under OS 4.1, SGI's under 5.0, on IBM PC's under DOS 6.2 and Windows 3.1, and on the Apple Macintosh under ThinkC 5.0. With this single language for defining the audio signal processing, and portable audio formats like AIFF and WAV, users can move easily from machine to machine.

The 1991 version added phase vocoder, FOF, and spectral data types. 1992 saw MIDI converter and control units, enabling Csound to be run from MIDI score-files and external keyboards. In 1994 the sound analysis programs (lpc, pvoc) were integrated into the main load module, enabling all Csound processing to be run from a single executable, and Cscore could pass scores directly to the orchestra for

iterative performance. The 1995 release introduced an expanded MIDI set with MIDI-based linseg, butterworth filters, granular synthesis, and an improved spectral-based pitch tracker. Of special importance was the addition of run-time event generating tools (Cscore and MIDI) allowing run-time sensing and response setups that enable interactive composition and experiment. It appeared that real-time software synthesis was now showing some real promise.

# History of the Canonical Csound Reference Manual

This initial version of this manual for early versions of Csound was started at MIT by Barry L. Vercoe and maintained there during the 1980's and start of the 1990's. Some of the manual comes from documents for programs like *Music11* from the 1970's. This original manual was improved and worked on by Richard Boulanger, John ffitch, Jean Piché and Rasmus Ekman.

This manual led to the Official Csound Reference Manual, still located at: <http://www.lakewoodsound.com/csound> [<http://www.lakewoodsound.com/csound/hypertext/manual.htm>], for Csound version 4.16, November, 1999, which was maintained by David M. Boothe.

A parallel version of the manual called the Alternative Csound Reference Manual, was developed by Kevin Conder using DocBook/SGML [<http://www.docbook.org/>]. This version later became the Canonical version.

When Csound was licenced as LGPL by MIT in 2003, the manual was licenced GFDL and placed on Sourceforge along with the sources of Csound.

In the winter of 2004, the Canonical Manual was converted to DocBook/XML by Steven Yi to allow for more people to be able to compile and maintain the manual.

The manual is currently maintained by Andrés Cabrera with continuous contributions from the Csound Community.

The manual continues to be a community run project that depends on the contributions of developers and users to help refine the coverage and accuracy of its contents. All contributions are welcome and appreciated.

# Getting Started with Csound

## Downloading

In case you don't already have Csound (or have an older version) download the appropriate Csound version for your platform from the *Sourceforge Csound Download Page* [<http://sourceforge.net/projects/csound/files/>]. Installers for Windows have '.exe' extension and for Mac '.dmg'. If the installer's filename ends in '-d' it means the installer has been built with *double* precision (64-bit) which provides higher quality output than the ordinary *float* precision (32-bit). The float versions provide quicker output, which may be important if you're using Csound in a real-time setting. You can also download the sources and build them, but this requires more expertise (See the section *Building Csound*).

It may also be useful to download the most recent version of this manual, which you will also find there.

## Running

Csound can be run in different ways. Since Csound is a command line program (DOS in Windows terms), just clicking on the csound executable will have no effect. Csound must be called either from the computer's command line or from a front end. To use Csound from the command line, you must open a *Terminal* (Command Prompt or DOS Prompt on Windows, or Terminal on MacOS). Using Csound from the command line can be difficult if you've never used a terminal, so you may want to try to use one of the front ends, either QuteCsound, which is included with the latest distributions, or another front end. A *front end* is a window-based (not necessarily Windows-based) program that assists running Csound. Most front ends include text editors with which you can edit csound files, and many include other useful features.

Whether being run from a front end or being executed from the command line, Csound needs two things:

- A Csound file ('.csd' or possibly an '.orc' and a '.sco' file)
- A list of command line flags (or configuration options) that configure execution. They determine things like output filename and format, whether real-time audio and MIDI are enabled, which audio output to use for real-time audio, the buffer size, the types of messages printed, etc. These options can be included in the '.csd' file itself, so for the examples included in this manual *you shouldn't need to worry about them*. Front end programs often have dialog boxes in which the command line flags can be set. The complete and very long list of available command flags can be found *here*, but you might want to have a look there later...

See the section *Configuring* if Csound is giving you trouble.

This documentation includes many '.csd' files which you can try out, and which should work directly from the command line or from any front end. A simple example is *oscil.csd* [examples/oscil.csd], which can be found in the *examples* folder of this documentation. Your front end should allow you to load the file, and the front end should have a 'play' or 'render' button that will allow you to hear the file. If you want to experiment with the file, you're well advised to use the front end's 'Save As...' command to copy it to some other directory on your hard drive, such as a 'csound scores' directory that you create.

### Note for MacCsound users

You might need to remove all the lines from the command options slot in order for the manual examples to work.

You can also try the manual examples from the command line. To do this, navigate to the examples dir-

ecitory of the manual using something like this on Windows (assuming the manual is located at c:\Program Files\Csound\manual\):

```
cd "c:\Program Files\Csound\doc\manual\examples"
```

or something like:

```
cd /manualdirectory/manual/examples
```

for the Mac or linux Terminal. Then type:

```
csound oscil.csd
```

The example files are configured to run in real time by default, so with this command you should hear a two-second sine wave.

## Writing your own .csd files

A .csd file looks like this (this file is *oscils.csd* [examples/oscils.csd]):

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac    ;;;realtime audio out
;-iadc   ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime ouput leave only the line below:
; -o oscils.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1

iflg = p4
asig oscils .7, 220, 0, iflg
    outs asig, asig

endin
</CsInstruments>
<CsScore>

i 1 0 2 0
i 1 3 2 2 ;double precision
e
</CsScore>
</CsoundSynthesizer>
```

Csound's .csd files have three main sections between the *<CsSynthesizer>* and *</CsSynthesizer>* tags:

- *CsOptions* - Includes the *Command Line flags* specific to this particular file. These options can also be set using the *.csoundrc* file, which you can edit in a text editor, or directly in the *command line*. Some front ends also provide ways to specify global or local options.
- *CsInstruments* - Contains the instruments or processes available in the file. Instruments are defined using the *instr* and *endin* opcodes. The *CsInstruments* section also contains the *Orchestra Header*, which defines things like *sample rate*, the *number of samples in a control period*, and the *number of output channels*.
- *CsScore* - Contains the 'notes' to be played, and optionally the definition of f-tables. Notes are created

using the *i statement*, and f-tables are created using the *f statement*. Several other *score statements* are available.

Anything after a semicolon (;) until the end of the line is a comment, and is ignored by Csound.

You can write .csd files in any plain text editor, such as Notepad or Textedit. If you use a word processor (not recommended), be sure to save the file as plain text (not rich text). Many *front ends* include advanced editing capabilities, such as syntax highlighting and auto-completion of code.

You can find an in-depth tutorial on getting started with Csound written by Michael Gogins here [<http://michael-gogins.com/archives/tutorial.pdf>].

## What's new in Csound 6.06

### Release Notes for Csound 6.06 (2015 September)

A number of bug fixes, some quite major, are included, as well as some new facilities and extensions.

- New opcodes:
  - getseed reads the state of the PRN generator; opposite of seed opcode.
  - tabifd — Instantaneous Frequency Distribution, magnitude and phase analysis.
  - websocket — Read and write signals and arrays using a websocket connection.
  - framebuffer — Read audio signals into 1 dimensional k-rate arrays and vice-versa with a specified buffer size.
  - olabuffer — Sum overlapping frames of audio as k-rate arrays and read as an audio signal
- Orchestra:
  - Labels are allowed in instrument 0.
- Score:
  - Maximum string length in scores increased to 1024.
- Modified Opcodes and Gens:
  - diskin2 array version uses array size to give number of channels in raw file form.
  - diskin2 now has the kpitch parameter defaulting to 1 for simple use.
  - Vibrato f-table in wgflute and wgcarr optional, defaulting to sine wave.
  - schedule now accept string arguments.
  - urandom now available on OSX platforms.
  - GEN18 had fencepost problem; largely rewritten.
  - In poscil family of opcodes it is possible to skip initialisation of phase.
  - svfilter now can skip initialisation.

- When opening an input file nchncls\_i is used rather than nchnls. This is a change that should have followed the existence of nchnls\_i
- rtjack module now reports the sampling rate.
- The opcodes rfft, rifft, fft, fftinv, r2c and c2r now have i-rate array versions.
- New optional threshhold parameter in opcodes tradsyn, sinsyn and resyn.
- New thresholding option for partials.
- Utilities:
  - extract fixed.
  - src\_conv improved and integrated with -U options.
  - fixes in atsa, and heti.
- Frontends:
  - pnacl:
    - Support for 48000 sample rate fixed.
  - csound~:
    - Changes to the threading system. String channel initialisation fixed. A number of other bugs were fixed.
  - Emscripten:
    - Csound Javascript object can now receive data from the outvalue opcode.
  - HTML5:
    - Integrate HTML, JavaScript, and other features of HTML5 with Csound, either by embedding a Web page as an <html> element in the CSD file for CsoundQt or Csound for Android, or by hosting Csound in the JavaScript context of a standalone Web browser (Emscripten, PNaCl) or embedded Web browser (csound.node).
- General usage:
  - Ill-formatted macros in the orchestra now trapped.
- Bugs fixed:
  - Use of Windows-style environments for INCDIR etc now works with device numbers.
  - vibrato opcode fixed.
  - Clicking in real-time sample accurate case fixed.
  - Copying of strings now correct; did confuse memory sometimes.
  - Bug in pvstanal fixed.
  - Rounding error in cpspch fixed.

- Removed crash on recompiling a named instrument.
- Fix interpolation bug in tablexkt.
- Fix to plltrack when ksmmps is 1.
- System changes:
  - The "error" message from STK plugin is now a warning.
- API:
  - Redefinition of opcodes and UDOs fixed.
- Platform Specific:
  - OSX.
    - csnd6.jar link installed in the correct location.
    - Java JNI linking issues solved.
    - fixed link name for libpng in libfltk\_image.

## Release Notes for Csound 6.05 (2015 April)

As ever there are new facilities and numerous bug-fixes. A major part of this release is the removal of a number of memory leaks and over use of memory. Naturally these changes are all but invisible, just a smaller memory foot-print. Note that we track bugs and requests for enhancements via the github issues system, and these had a significant affect on this release.

- Opcodes :
  - The opcode sndload is now deprecated.
- New Gen and Macros:
  - Paul Octavian Nasca's padsynth algorithm implemented as a gen.
- Score:
  - Fixed string location calculation bug when processing score lines [fixes #443]
- Options:
  - A short-format copyright option is available, with a fixed number of well-known licences (CC, etc)
  - New command-line option to report MIDI devices in simple format
  - New command-line option to set ksmmps
- Modified Opcodes and Gens:
  - *adsynt* handles amplitude changes better

- *sfont* has better checking for corruptions
- better checking in physical models for out-of-range frequencies
- *ftgenonce* and others allows string parameters
- *gausstrig* reworked and extended with new features
- use of *p()* function no longer complains overrides the pcnt warning
- fix to *midirecv*
- *OSCsend* cleans up after use improved
- *fillarray* is limited to 1 or 2 dimensional arrays; in fact it failed silently previously for 3D and higher.
- *oscbnk* now works when the equaliser is used.
- *mp3in* now works with both mono and stereo input files
- *flooper* & *flooper2* now allow stereo tables
- Release phase of *expsegr* fixed
- f-tables created by a large number of arguments could overwrite memory, now fixed
- performance of *plltrack* improved
- init of arrays clarified and checked
- *gen23* corrected to stop an infinite loop
- *alwayson* now starts from score offset; this is part of a fix to the long-standing problem with *alwayson* in CsoundVST
- *invalue* now checks for output string size and reallocates memory if smaller than default string size (set at 256 bytes for backwards compatibility)
- Utilities:
  - The *srconv* utility has been improved but it does not work well, with groups of noise in otherwise good output. We recommend the use of Erik de Castro Lopo's Secret Rabbit Code (aka *libsamplerate*) as providing sample rate conversion at high quality. *srconv* will be removed shortly possibly to be replaced by an SRC-based utility.
- Frontends:
  - *pnacl*
    - Added interface to allow the use of Csound's MIDI input system.
    - Fixed audio input to conform to the latest Pepper API spec.
- Bugs fixed:
  - bugs in *fastabi*, *oscktp*, *phasorbnk*, *adsr*, *xadsr*, *hrtfer* fixed.
  - bugs in the *harmon*, *harmon2*, *harmon3* and *harmon4* fixed.

- Csound could crash after a parsing error, a case now removed.
- System changes:
  - There are now checks that xin/xout types match those defined as part of UDO definition.
  - jack now has a timeout.
- Internal Changes:
  - Many defects indicated by coverity fixed or code changed. Should make csound more robust in edge cases.
  - Parser-related changes simplifies allocation of temporary variables, with some new optimisations.
  - code for multi-thread rendering improved and stabilised vis-a-vis redefinition of instruments.
- Platform Specific:
  - iOS.
    - Fixed audio callback to work correctly with lightning output and Apple TV.
  - Android.
    - New experimental audio IO mode: csoundPerformKsmmps() is called from the OpenSL ES output callback. This mode can be optionally enabled by passing a value of "false" to a new second parameter to the CsoundObj constructor (bool isAsync). The default constructor and the one-parameter sets this to "true" (keeping backwards compatibility with existing code).
    - The OSC opcodes are included in distribution.
    - Android app
      - There are new file open and save dialogs that permit the user to access the SD card on the device, if there is one, in addition to internal storage.
      - There is a new "Save as..." button that permits the user to save the csd as a new file with a new name.
      - Many of the examples in the archive of Android examples are now built into the app and can be run from the app's menu.
      - Includes now the exciter opcode.
  - OSX.
    - Installation now places csladspa.so rather than csladspa.dylib on disk.
  - Linux.
    - Linux is now build without FLTK threads. This removes system hangs and is in line with other builds.

## Release Notes for Csound 6.04 (2014 November)

This new version has many extensions and fixes; many new opcodes and significant numbers of internal

reworking. There is a new frontend and iOS and Android version have seen many improvements.

As ever we track bugs and requests for enhancements via the github issues system. Already proposals for the next release are being made but the volume of changes require a release now.

- New opcodes:
  - *pinker* generates high quality pink noise.
  - power opcode  $\wedge$  now works with array arguments.
  - *exciter* opcode, modelled on the calf plugin.
  - *vactrol* opcode simulates an analog envelope follower.
  - family of hdf5 opcodes to handle hdf5 format files.
  - (experimental undocumented) buchla opcode models the lowgate filter of Buchla.
- New k-rate opcodes acting on arrays:
  - transforms: rfft, rifft, fft, fftinv
  - complex product: complxprod
  - polar - rectangular conversion: rect2pol, pol2rect, mags, phs
  - real - complex: r2c, c2r
  - windowing: window
  - cepstrum: pvscpes, iceps, ceps
  - column / row access: getrow, getcol, setrow, setcol
  - a-rate data - k-array copy: shiftin, shiftout
  - phase unwrapping: unwrap
- New Gen and Macros:
  - Line numbers corrected in instr statements.
  - New control operation, while, for looping.
  - A long-standing bug with macros which use the same name for an argument has been corrected.
  - Redefinition of an instrument in a single call to compile is flagged as an error.
  - ID3 header skip for mp3 files now properly implemented.
  - Errors induced by not defining the location of STK's raw wave files has been removed.
  - bug fixed where UDO's could not read strings from pfields.
- Modified Opcodes and Gens:
  - stackops opcodes deprecated.

- lenarray extended to handle multi-dimensional arrays.
- ftgenonce accepts string arguments correctly and multiple string arguments.
- max and min now have initialisation-time versions.
- gen23 improved regarding comments and reporting problems.
- in OSCsend the port is now a k-rate value.
- socksend now works at k-rate.
- a number of envelope-generating opcodes are now correct in sample-accurate mode.
- faust compilation is now lock-protected.
- mp3 fixed to allow reinit to be used with it.
- In remote opcode the name of the network can be set via the environment variable CS\_NETWORK. Defaults to en0 (OSX) or eth0.
- Frontends:
  - icsound: New frontend icsound is now ready for general use. icsound is a python interface for interactive work in the ipython notebook.
  - csdebugger: A number of changes and improvements have been made, like stepping through active instruments, better line number use.
- General usage:
  - Jack module now does not stop Csound if autoconnect fails.
- Bugs fixed:
  - atsinnoi fixed.
  - ftsavek fixed.
  - sprintf fixed.
  - gen27 fixed, especially with extended arguments, as well as fixed a number of errors in extended score arguments.
  - Physem opcodes (guiro cabasa, sekere) fixed so second call works.
  - flooper fixed in mode 2.
  - OSCsend multiple fixes.
  - UDO fix for case of local ksmmps of 1.
  - More changes/fixes to dssi code.
  - xscanu and scanu fixed.
  - temposcal and mincer fixed.
  - crash in ftload fixed.

- System changes:
  - In server mode exit is now clean.
  - Fixes to rtalsa module.
  - Pulseaudio rt module fixes.
  - Fix to remove fluidEngine entries for csound instance (prevents crash on moduleDestroy).
  - Opcodes called through function calls that returned arrays did not correctly synthesize args as array types due to not converting the arg specifier to the internal format.
  - fixed crashing issue during note initialization for tied notes due to goto skipping over code.
  - fixed incorrect initialization of pfields when note's fields length were less than instrument expected (off-by-one).
- Internal Changes:
  - Added Runtime Type Identification for instrument variables; removed use of XINCODE/XOUTCO.
  - fix malloc length in negative number parsing, and improved handling of negative numbers.
  - writing to circularBuffer is now atomic.
  - a number of memory leaks and potential dangerous code have been fixed.
  - type-inference has been extensively reworked, as have a few parsing areas.
- API:
  - Added API function for retrieving GEN parameters used for creating a table.
- Platform Specific:
  - iOS.
    - API Refactored for clearer method names and abstraction names (i.e. CsoundBinding instead of CsoundValueCacheable).
    - Updated to remove deprecated code.
    - A significant amount of reworking has been done on the code.
  - Android.
    - API Refactored for clearer method names and abstraction names (i.e. CsoundBinding instead of CsoundValueCacheable).
    - Changes to enable HTML 5 with JavaScript and it is to be hoped WebGL in the Csound6 Android app.
    - Enabled change of screen orientation in the Csound6 app without forcing a restart of the app.
    - Enabled local storage (useful for saving and restoring widget values, etc.).
  - Windows.

- fixed pointer arithmetic that caused crashing on Windows.
- pyexec changed to use python's file opening functions to prevent crash on Windows.
- OSX.
  - CsoundAC now compiles.
  - Linux.
    - threadlocks bug fix on linux.

## Release Notes for Csound 6.03 (2014 May)

This new version has a large number of bug fixes (including clearing many tickets on SourceForge and GitHub) as well internal changes to improve performance.

- New opcodes:
  - `prinks2`  
: prints a new value every time a control variable changes using a printf() style syntax
  - `mp3sr`, `mp3bitrate`, and `mp3nchnls` to get information on mp3 files
  - EXPERIMENTAL: CUDA opcodes for partitioned convolution direct convolution and sliding phase vocoding; OpenCL opcode for additive synthesis
  - `compilecsd`  
to compile instruments from a standard CSD file
- Orchestra:
  - The argument for `i()` is supposed to be a variable not an expression. This is now enforced. (bug #90)
- Score:
  - New score opcode `y` sets the random seed (for `~`) at read time
- Options:
  - There was a bug in `CsOptions`; the last argument was missed being read(issue #296)
  - As command-line options `expression-opt` and `no-expression-opt` do nothing in Csound6 a warning is printed
- Modified OpCodes and Gens:
  - For ogg output it is possible to specify a VBR (variable block rate) quality.
  - `dssi4cs` code has been extensively reworked to avoid potential memory faults.
  - Many array operations now available for i-arrays as well as k-arrays.
  - `fillarray` will work for string arrays

- Displays of FFT (via *dispfft*) improved with scaling/zooming options
- Signal flow graph opcodes are now working with a-rate array signals.
- In alsal RT code the sample rate is taken from the device
- Faust opcode system updated to latest faust API
- Utilities:
  - fixed bug in lpanal
- csound~:
  - OSX - fix for running with 32-bit cpu architecture
  - Windows - csound~ now available for Windows
- Emscripten:
  - This is now generally merged into the code-base
- General usage:
  - --displays now switches graphs on, as expected
  - New commandline option --get-system-sr added to obtain the machine's sample rate
  - New command-line option --devices[=in|out] gives a list of available audio devices and then exit
- Bug fixes:
  - fixed the bug when tables were replaced but the size did not change
  - A number of bugs in --sample-accurate have been detected and fixed. This includes opcodes *out*, *outn*, and *line*
  - A number of bugs in *grain3* were fixed
  - Bug in *str\_chanel* could cause a crash; fixed
  - Small bug in *rtjack* fixed
  - Error in *resize* opcode corrected
  - Fixed an unlikely bug in *atsa*
  - Fixed rtauhal pause issue
  - A number of bugs/untidiness fixed in GEN23
  - Array bound checks fixed
  - strings channels were not correctly set for dynamic-size strings, now fixed
  - memory allocation for string formatting in *printfsk* was fixed, stopping string truncation
  - *strcat* safe against overflow

- error in compilation of arrays fixed (issue #293)
- *GetPvsChannel* fixed against a crash
- System Changes:
  - *turnoff* opcode now checks that the instrument being affected is active
  - *lenarray* can accept any array type
  - the way of rounding a table number to an integer was changed and is now more as expected
  - there is a new possible section in a csd file called <CsFile...> which is like csFileB but with unencoded text.
  - UDO compilation now uses the type system. This means that UDOs now allow any array type to be used
  - Improved orchestra parsing speeds with better algorithms
- Internal Changes:
  - The whole system has been checked by the Coverity static checker which identified a number of (mainly minor) problems. These have been reviewed and checked. In particular better use of printing and string copying should prevent overflows
  - The type and variable system has been extensively rewritten; this allows better array and UDO support
  - Alignment of variables got right in all cases
  - Array copying is now using the type system to copy values; fixes issues with copying string arrays, f-sigs, etc
  - Always reset Csound when stopping to ensure state is clean; was not being reset when there was a compile error, so that next successful run would start with an invalid Csound engine (issue #305)
- API:
  - All opcodes etc now use the API memory allocation operations, so it is possible to replace the whole memory allocator
  - Added *csoundCompileCsd* to API and associated new *compilecsd* opcode
  - Protected *csoundGetStringChannel* against null and short strings and added a check for string size
  - A number of API functions have had char\* changed to const char\* which reflect the usage

The performance engine now includes debugging capabilities to allow interrupting rendering and providing introspection into the engine's state and instrument variables. The following new functions are available by including the csdebug.h header:

```
void csoundDebuggerInit (CSOUND *csound);
void csoundDebuggerClean (CSOUND *csound);
void csoundSetInstrumentBreakpoint (CSOUND *csound, MYFLT instr, int skip);
void csoundRemoveInstrumentBreakpoint (CSOUND *csound, MYFLT instr);
void csoundClearBreakpoints (CSOUND *csound);
void csoundSetBreakpointCallback (CSOUND *csound, breakpoint_cb_t bkpt_cb, void *userdata);
void csoundDebugContinue (CSOUND *csound);
void csoundDebugStop (CSOUND *csound);
debug_instr_t *csoundDebugGetInstrInstances(CSOUND *csound);
void csoundDebugFreeInstrInstances(CSOUND *csound, debug_instr_t *instr);
```

```
debug_variable_t *csoundDebugGetVariables(CSOUND *csound, debug_instr_t *instr);
void csoundDebugFreeVariables(CSOUND *csound, debug_variable_t *varHead);
```

- Windows:
  - Soundfonts in Windows had an internal alignment problem which is fixed

## Release Notes for Csound 6.02

This new version has a large number of bug fixes (including clearing all general tickets on SourceForge). It also introduces some major new facilities such as use as a server, code to run Csound in a browser and a large generalisation of filter opcodes to have parameters changeable at audio rate.

- New opcodes:
  - *ninstance* opcode schedules a new instrument instance, storing the instance handle.
  - *turnoff nw* variant to stop a given instrument instance.
  - *strfromurl* to set a string from a URL.
- Orchestra:
  - If building supports it, a #include string can be a URL or a file.
  - A space is again permitted between a function name and the opening bracket for all functions allowed in Csound5 (but not in general).
  - The Csound command can start with an empty CSD in daemon mode (--daemon): do not exit if CSD/orchestra is not given, is empty or does not compile).
- Score:
  - If building supports it, a #include string can be a URL or a file.
- Modified Opcodes and Gens:
  - Many filters generalised to allow k- or a-rate parameters. In particular it includes these:

|                     |          |
|---------------------|----------|
| areson              | atonex   |
| butterworth filters | fofilter |
| lowres              | lowresx  |
| lpf18               | mode     |
| moogladder          | moogvcf  |
| reson               | resonr   |
| resonx              | resonz   |
| statevar            | tonex    |

- The maximum number of presets in sfont increased to 16384.
- *cpsmidinn* is now more accurate.

- *max\_k* now behaves like the documentation. There were cases when it gave strange results.
- The vst4cs opcodes have been re-factored. FLTK code has been encapsulated. The build system has been updated for Csound 6.
- In *alwayson* opcode changes for better handling of pfields, more reliable insert of an instrument instance for repeating or re-started score sections.
- The signal flow graph opcodes have replaced OpenMP multi-threading with pthreads, using one-time initialization of static structures.
- Frontends:
  - PNaCl is now supported as a platform, allowing Csound to run under the Chrome browser in all enabled operating systems.
- Bugs fixed:
  - *adsynt2* opcode fixed.
  - *ftgentmp* opcode fixed.
  - *dates* opcode fixed.
  - fixed a bug in *pvsfilter*.
  - fixed stereo out in *tempascal* and *mincer*.
  - *pan2* opcode fixed.
  - index overflow in *randh* and *randi* fixed.
  - A number of fixes to CsoundVST: initialization, score handling, and MIDI driver initialization, so it now works for Csound 6.
  - fixed *pycalln* for no inputs.
  - fixed/revised setting and use of *ksmps* and *kr* in UDOs.
  - fixed problem in sending a score event from max to csound via csound~ (Ticket #58).
  - If itype in *chn\_k* was set to 3 and values are set less than 1, Csound6 used to give an INIT Error. (Ticket #67).
  - A number of reported seg faults have been dealt with.
  - *xtratim* opcode was using incorrect ekr value from csound instead of from instance; when used in conjunction with *setksmps*, was causing notes to have very long *xtratim* set and thus notes were effectively not getting turned off
- System changes:
  - A server mode is now available, accepting input via UDP (with --port option).
  - A longstanding bug in extract was detected and fixed. It does suggest that this facility is little used!
  - The way the external score generator was coded is substantially changed. In particular this should fix a very strange bug in Windows.

- Fixed crashing bug with invalid channel callback due to wrong data object being pulled from csound host data.
- Fixed bug in UDOs with no local ksmps where kcounter was being used incorrectly.
- Better checking in channels.
- (Experimental) If the environment variable CSUDO\_DIR is set then any files in the directory that have an .udo extension are automatically included at the start of the orchestra. This facility needs review to see if it is what is required.
- (Experimental) There are new cuda GPGPU opcodes (source only): cudasynth (3 versions for additive synthesis, additive synthesis of fsigs and phase vocoder resynthesis) and cudanal (a GPGPU version of pvsanal).
- Internal changes:
  - Many attempts at faster code.
  - Type inference and parsing still improving.
- iOS:
  - Fixed crash where no csoundSetHostImplementedMIDIIO is used on iOS and no \_RTMIDI value is set.
- OSX:
  - Fixed input device name for auhal.

## Release Notes for Csound6

Csound6 is a significant rewrite of much of the code. In particular the API is not compatible, although all orc/sco/csd works should still run.

There are new facilities, like sample accuracy and realtime mode, described below.

**IMPORTANT:** The environment variable to find plugins are called **OPCODE6DIR64** or **OPCODE6DIR** (note the 6) so it can co-exist with Csound5.

Similarly **.csoundrc** is renamed **.csound6rc**.

Arrays are now mainstream, with syntax and opcode support. They also exist in multidimensional format. They are created (usually) with *init* opcode or *fillarray*.

```
k1[] init 4
```

generates a k-rate 1-D array of length 4. Similarly

```
a2[][] init 4, 4
```

creates a square 4x4 a-rate array.

```
k2[] fillarray 1, 2, 3, 4
```

creates a 4-element vector filled with 1..4, which also defines the length.

Elements are used via indexing in [] such as k1[2] or a2[2][3]. One dimensional arrays replace tvars, and can be used in opcodes like *maxtab*, *mintab* and *sumtab* (see below). Array setting can be done in left-hand side of opcodes, i.e.:

```
aSigs[0] vco2 .1, 440  
aSigs[1] vco2 .1, 880
```

The new realtime priority mode can be switched on with by passing the --realtime or setting the CSOUND\_PARAMS field realtime\_mode to 1. This has the following effects:

1. all opcode audio file reading/writing is handled asynchronously by a separate thread.
2. all init-pass operations are also performed asynchronously.

Multicore support is totally rewritten using a different algorithm for task-dispatch, which should use less memory and fewer locks.

- New opcodes:
  - *faustgen*
  - *array* -- many new or revised opcodes -- see *Array Opcodes*.
  - *compileorc* takes a filename containing a collection of instrument definitions and compiles them, replacing existing versions. It returns 0 on success.
  - *compilestr* is like *compileorc* but takes a string.
  - *readscore* runs the score preprocessor on a string and then schedules new events via the RT event mechanism, returning 0 if successful.
- Orchestra
  - Note events can start and end in mid-kcycle. As this is an incompatible change it is only invoked when the command-line option --sample-accurate is specified. Note that this does not work for tied notes, and use of skipping initialisation has questionable use.
  - Instruments can run at local *ksmps* values using *setksmps ikmps* as in Csound 5 UDOs.
  - Compilation can be done at any stage, new instruments are added or replace old ones. Running instances of old instrument definitions are not affected. Only limitation is that header constants in instr 0 are read only once at the time of the first compilation. Init-time code can be placed outside instruments in the global space, and this will be executed once-only following the compilation. In this case, score event generation can be completely replaced by orchestra code. See also new opcodes *compileorc* and *compilestr*.
- New syntax operators  $+=$ ,  $-=$ ,  $*=$  and  $/=$ . These are more than syntactic sugar; please use  $+=$  and  $-=$

for accumulating reverbs as it gives better multicore behaviour.

- The opcodes *add*, *sub*, *mul* and *div* have been deleted; use the forms  $+ - * /$ . Not many people were aware of these opcodes.
- Any opcode with a single output or with no outputs can be used as a function. Some opcodes might require type annotation to resolve ambiguities, more details on the *Function syntax in Csound 6*.
- A statement can be broken across lines after a `,` = or arithmetic operation.
- There are a range of new or recoded operations on k-valued arrays, most restricted to 1 dimensional arrays (vectors):

```
kans minarray ktab      returns the smallest value in the
                        (possibly) multidimensional array
kans maxarray ktab      is like mintab
kabs sumarray ktab      returns sum of all values in the array
ktab genarray imin, imax[, inc]
                        generates vector of values from imin
                        to imax by increments of inc (default 1)
ktab2 maparray ktab1, "sin" maps the k-rate 1-arg function in
                        the string to every element of the vector
ktab2 maparray_i ktab1, "sin" maps the i-rate 1-arg function
                        in the string to every element of the vector
ktab2 slicearray ktab1, istart, iend
                        returns a slice of ktab1 from ktab1[istart]
                        to ktab1[iend]
copyf2array ktab, kfn   copies data from an ftable to a vector
copya2ftab ktab, kfn   copies data from a vector to an ftable
```

Arithmetic on arrays is allowed. In particular addition, subtraction, multiplication, division on a element-by-element version is provided in arithmetic format. Similar operations between an array and a scalar are allowed.

- Each instance of any instrument has a scratchpad of 4 values that persist; allows values to carry to next use of the instrument; hope it may be useful in legato etc.
- If a table number is given as -1 then an internal sine wave equivalent to `f. 0 16382 10 1` is used. Attempts to write to this table will give unpredictable results, but is not policed. The 16382 can be change by command line option `--sine-size=#` where the # is rounded up to a power of two.
- A number of oscil opcodes now have the f-table parameter as optional, defaulting to the internal sine wave. (`oscil1, oscil1i, oscil, oscil3, oscili, oscilf, oscil1, loscil, loscil3`).
- Score:
  - Score lines can have multiple strings.
  - Change to escape characters in score strings -- they do not happen.
  - Also note the *readscore* opcode.
- Modified Opcodes and Gens:
  - The *k()* function can take an a-rate argument in which case it is a call to *downsamp*.
- Utilities
  - *Hetro/adsyn* analysis files can be machine byte-order independent if created with -X. Down side is a longer file and a little slower loading. The *het\_export* utility will create the independent format

from the old, and *het\_import* is no longer necessary.

- *cval* and *lpanal* will produce machine independent files if -X option is used. The *convolve* and *lpread* etc opcodes will accept either format. You are encouraged to use the machine independent form. Analysis files produced with -X can be used on other systems.

- Frontends

- Bugs fixed:

- System Changes:

- In Linux and OSX the treatment of locales is now thread-safe and local.

- Platform Changes:

- API:

New API functions...

- new configuration/parameter setting functions

```
PUBLIC int csoundSetOption(CSOUND *csound, char *option);
PUBLIC void csoundSetParams(CSOUND *csound, CSOUND_PARAMS *p);
PUBLIC void csoundGetParams(CSOUND *csound, CSOUND_PARAMS *p);
PUBLIC void csoundSetOutput(CSOUND *csound, char *name, char *type,
                           char *format);
PUBLIC void csoundSetInput(CSOUND *csound, char *name);
PUBLIC void csoundSetMIDIInput(CSOUND *csound, char *name);
PUBLIC void csoundSetMIDIFileInput(CSOUND *csound, char *name);
PUBLIC void csoundSetMIDIOutput(CSOUND *csound, char *name);
PUBLIC void csoundSetMIDIFileOutput(CSOUND *csound, char *name);
```

- new parsing/compilation functions

```
PUBLIC TREE *csoundParseOrc(CSOUND *csound, char *str);
PUBLIC int csoundCompileTree(CSOUND *csound, TREE *root);
PUBLIC int csoundCompileOrc(CSOUND *csound, const char *str);
PUBLIC int csoundReadScore(CSOUND *csound, char *str);
PUBLIC int csoundCompileArgs(CSOUND *, int argc, char **argv);
```

- new function for starting csound after first compilation

```
PUBLIC int csoundStart(CSOUND *csound);
```

- new software bus threadsafe getters/setters

```
PUBLIC MYFLT csoundGetControlChannel(CSOUND *csound, const char *name);
PUBLIC void csoundSetControlChannel(CSOUND *csound, const char *name, MYFLT val);
PUBLIC void csoundGetAudioChannel(CSOUND *csound, const char *name, MYFLT *samples);
PUBLIC void csoundSetAudioChannel(CSOUND *csound, const char *name, MYFLT *samples);
PUBLIC void csoundGetStringChannel(CSOUND *csound, const char *name, char *string);
PUBLIC void csoundGetStringChannel(CSOUND *csound, const char *name, char *string);
```

- new table threadsafe copy functions

```
PUBLIC void csoundTableCopyOut(CSOUND *csound, int table, MYFLT *dest);
PUBLIC void csoundTableCopyIn(CSOUND *csound, int table, MYFLT *src);
```

API has been made threadsafe so that performance and control can occur in separate threads (after a call to *csoundStart()* or *csoundCompile()*). Threadsafety is ensure by

1. use of atomic read/writing to control channels
2. spinlocks in audio and string channels
3. mutexes protecting compilation, score events and table access.

- Internal:

- The build system is now cmake (and not scons as in Csound5).
- A number of table access opcodes have been rewritten but should behave the same. Similarly *diskin* and *diskin2* now use the same code and so *diskin* should be more stable.
- The old parser is completely removed.

- New internal functions in Csound

```
void (*FlushCircularBuffer)(CSOUND *, void *);
void *(*FileOpenAsync)(CSOUND *, void *, int, const char *, void *,
                      const char *, int, int, int);
unsigned int (*ReadAsync)(CSOUND *, void *, MYFLT *, int);
unsigned int (*WriteAsync)(CSOUND *, void *, MYFLT *, int);
int (*FSeekAsync)(CSOUND *, void *, int, int);
char *(*GetString)(CSOUND *, MYFLT);
Extract a string originating from a score-event argument.
```

- Functions removed

```
void *(*FileOpen)(CSOUND *, void*, int, const char*, void*, const char*);
```

- The "private" parts of the API have been changed considerably. Also structures like EVTBLK have changed.
- The **LINKAGE1/FLINKAGE1** macros are renamed as **LINK-  
AGE\_BUILTIN/FLINKAGE\_BUILTIN**.
- Template for a-rate perf-pass opcodes is

```
int perf_myopcode(CSOUND *csound, MYOPCODE *p)
{
    uint32_t offset = p->h.insdshead->ksmps_offset;
    uint32_t early = p->h.insdshead->ksmps_no_end;
    uint32_t nsmpls = CS_KSMPS;
    ...
    if (UNLIKELY(offset)) memset(p->res, '\0', offset*sizeof(MYFLT));
    if (UNLIKELY(early)) {
```

```
    nsmps -= early;
    memset(&p->res[nsmps], '\0', early*sizeof(MYFLT));
}
for (n=offset; n<nsmps; n++) {
    ....
    p->res[n] = ....
}
return OK;
}
```

- String variables re-implemented
- OENTRY structure has changed and has a new dependency field; please use this field as it is required for multicore semantics. You could set it to -1 and disallow all parallelism, but at least it is safe.
- All opcodes that touch audio should take note of sample-accurate code.
- A number of previous API functions are removed; *OpenFile* and *OpenFile2* both replaced by new *OpenFile2* with additional argument.
- Additions have been made for arg type specifications for opcodes.
  - Any-types have been added, as follows:
    - '.' signifies a required arg of any-type
    - '?' signifies an optional arg of any-type
    - '\*' signifies a var-arg list of any-type
  - Arrays are now specified using "[x]" where x is a type-specifier. The type-specifier can be any of the current specifiers, including any-types. See *Opcodes/arrays.c* for example usage.
- New Type System

A new type system has been added to Csound6, and significant changes have been made to the compiler. The previous system for handling types involved depending on the first-letter of a variable's name every time it was used to determine type. This meant there was a lot of re-checking of types. Also, adding new types was difficult, as there was a lot of custom code that had to be updated to check for new type letters.

In Csound6, a separate system of types was added. Types are defined as CS\_TYPE's. The creation of variables from types and the initialisation of memory has been encapsulated within the CS\_TYPE's. This change allows easier addition of new types, as well as generic calculations of memory pools, amongst other things.

The compiler has been modified since Csound5 to now use the type system as an integral part of its semantic checking phase. Variables are now registered into a CS\_VAR\_POOL when they are first defined, with the CS\_VARIABLE having a reference to its CS\_TYPE. After first time definition within the pool, the type information is then looked up in consequent variable lookups, rather than recalculated from the variable name. This opens up possibilities for new variable naming and typing strategies, i.e. using "myVar:K" to denote a k-rate arg. This also opens up possibilities for user-defined types, such as "data myType kval, aval", then using "myVar:myType" to define a var of that type. (The previous is speculative, and is not an active proposal at this time.)

The addition of the type system has formalised the static type system that has existed in Csound prior to Csound6. It has, arguably, simplified the code-base in terms of type handling, as well as laid the ground work for future type-related research to be integrated into Csound.

## New in Version 5.19 (2013 January 7)

This is mainly a bug-fixing release but with a number of new opcodes and enhanced features.

- New opcodes:
  - *ipmidi* module for MIDI over network.
  - *ppltrack* opcode.
  - *combinv* opcode.
- New Gen and Macros:
  - Better checking in *GEN28*.
  - Check range in *outrg*, and optionally allow wrapping.
- Orchestra:
  - Change empty statement to a warning.
  - Added line numbers to many input args message (new parser).
- Modified Opcodes and GENs:
  - Better error and warning messages.
  - *loopseg* now checks argument count.
  - *harmon2/3/4* improved.
  - *active*: added the option to skip the instances in release phase.
  - New and more tested implementation of ChordSpace.
- Bug fixed:
  - Fix botched optimisation in lowpass filters.
  - Chn opcodes fixed in Linux.
  - Fix bug in *loscil* with silence.
  - Correct *GEN23* when comment does not end in newline.
  - Correcting *loopseg*.
  - Number of input and output channels fixed in new parser.
  - Fixed *GEN43* issue.
  - Fixed *fout*.
  - *centroid* was likely to crash.
  - Minor bug in printing which lost %.

- An uninitialised value in *fold* fixed.
- Uninitialised values in *dconv* fixed.
- Assignment of fsigs now works.
- System Changes:
  - Avoid seg fault on some user errors.
  - Faster modal4 opcodes.
  - Allow cabbage compilation.
  - Made pfield size dynamic in event message csoundapi~.
  - The default output format with pipe and double float is AU.
  - Change to ircam with default format, '-o stdout' and pipe.
  - Added double float precision for output format.
- Platform Changes:
  - Linux:
    - Spinlocks initialised (fixes bug in chn opcodes).
  - OSX:
    - Improved selection of devices in rtauhal module.
    - Added a circular buffer interface and lock-free operation to rtauhal.
    - Fixed MacOSX installer (creating symlinks to lib\_csnd.dylib).
  - Haiku:
    - New platform
  - Android:
    - Using -B now in android to set circular buffer size.
    - Added fluid synth opcodes for android.
    - Added inputMessage method to CsoundObj.
    - Allow CSDPlayer to be installed on SD Card.
  - iOS:
    - Improved audio routing.
    - Bottom speaker the default for iOS.
  - API:
    - Added new API function *csoundCompileFromStrings()*.

## New in Version 5.18 (2012 August 29)

This is mainly a bug-fixing release but with a number of new opcodes and enhanced features.

- New opcodes:
  - *centroid* opcode like *pvscent* but acting on audio signals
  - *cosseg* like *linseg* but with cosine interpolation
  - *cossegb* like *linsegb* but with cosine interpolation
  - *cossegr* like *linsegr* but with cosine interpolation
  - *joystick* to read input values from an external joystick (Linux only)
  - *log2* function for logarithms base 2
  - *platerev* opcode to model a reverberating square plate
  - *pwd* opcode to determine the current working directory
  - *readf* opcode to read strings from a file
  - *readfi* opcode to read strings from a file on initialisation
  - *vbap* opcode like other *vbap* family but flexible about number of speakers and choice of layouts.
  - *vbapg* opcode like *vbap* but only calculate the gains on the channels.
- New functionality
  - Changes to <CsOptions> to allow spaces between words, and escaped characters.
  - *fout* and *fin* use a better buffering strategy, and so are faster
  - It is possible to specify just an orchestra with the --orc flag. This is useful when a score is not needed.
  - A new command-line flag --ogg flag has been added for easy use of ogg/vorbis output.
  - Added alsaseq real-time midi
- Bug fixes and improvements:
  - *dates* opcode could crash on 64bit architecture; this is fixed
  - Some multicore interlocks were wrong. It is believed that this was not actually a problem, but would be in the future.
  - There were cases when a file was double closed, leading to a crash on exit.
  - Two new features added in *partikkel*. Panning law for channelmasks can now be set using a function table (second optional argument to *partikkel*) and new support opcodes *partikkelget* and *partikkelsen*, to access and modify the internal mask indices of *partikkel*.

- *follow2* was reworked do the i-rate and k-rate calculations are the same.
- *pvscent* is corrected as it returned half the correct value.
- *vbatislinit* can create more than one speaker layout which vbap/vbapg can use. Also much better diagnostics on incorrect layouts.
- Internal Changes:
  - Code changed so bison 2.6 can be used.
  - It is assumed that libsndfile version 1.0.19 or later is available.
  - If the score is omitted a near-infinite wait is generated.

## New in Version 5.17 (March 2012)

This is mainly a bug-fixing release with no major changes, but the number of fixes warrants a release.

- New opcodes:
  - *cell* opcode, for cellular automata
- Modified Opcodes and Gens:
  - active now will report total number of active or allocated instruments if argument in zero
  - stsend and strecv the TCP socket opcodes reworked to a logical design
  - DSSI system now will take up to 9 channels
  - FLsavesnap works with other widgets where imin > imax
- Utilities:
  - csbeats better documented and built by default; also more note lengths available
  - Some security holes in utilities fixed
- Bug fixes:
  - unirand opcode at a-rate fixed
  - Locale fix for floating point literals in orchestra
  - transegr fixed
- System Changes:
  - Score can now last longer (change to size of time variable)
  - An empty score gives a very long performance time (years and years)
  - Android code released

- Changes to use of tmp files; now all are deleted at end of run (previously some were left) and the environment variable TMPDIR is used.
- interaction between Comments, end of line and end of file fixed
- Hexadecimal numbers now allowed in orchestra
- Empty orchestra now not a crash
- change to macro expansion inside a string
- avoid infinite loop when eof in malformed score macro
- fixed macroname-with-args diagnostics and memory leak
- change to preprocessor: {{ }} inside "..." and better diagnostics
- fix windows installer so it removes full \$INSTDIR\bin from PATH during uninstall: this cleans up the PATH environment variable when uninstalling on Windows. Previously, it was leaving a trailing "\bin" on the PATH.
- CsoundAC MusicModel class more usable by C++ programs
- ftcps had been missed as a function
- Internal Changes:
  - Many! Some messages quietened, code improvements etc

## New in Version 5.16 (February 2012)

The major change is that the new parser is now the default. The old parser is still available in case of difficulty but the new has been given extensive testing since the start of the year, including complete restructuring of macro expansion. A side effect is that the runtime of most orchestras is faster, although parsing is slower. There are a few optimisations implemented like constant folding in simple cases. Line numbers and file names are traced better than before.

Some memory leaks also fixed.

- New opcodes:
  - Opcodes adapted from SuperCollider by Tito Latini: *dust*, *dust2*, *gausstrig*, *gendy*, *gendyc*, and *gendyx*.
  - Fractal noise generator by Tito Latini: *fractalnoise*.
  - Opcodes for accessing table values by direct indexing, by John ffitch: *ptable*, *ptablei*, *ptable3*, and *ptablew*. These opcodes are respectively like *table*, *tablei*, *table3*, and *tablew*, but they do not require a power-of-2 table size.
- Modified Opcodes and Gens:
  - There was a fence post problem in tab opcode that could falsely report a reference out of range.
  - GEN15 mis-called gens 13 and 14 internally, using uninitialised values voice amplitude. Problem

fixed.

- fmbell now takes an optional argument to control the sustain time.
- Change to pvsbasic for tab to table conversions.
- poscil is now polymorphic, allowing k- or a-rate amplitude and frequency.
- p() and i() changed when argument at k-rate.
- gen49 deferred now works.
- gen23 now available deferred.
- Utilities:
  - Checked for use with the new parser in memory files.
- Frontends:
  - Table access added to csoundapi~ via new get/set methods.
- Bug fixes and improvements:
  - Many in new parser related to precedence and multicore.
  - Better diagnostics when orchestra file/csd is missing.
  - csd file: fix CsFileB and CsSampleB.
  - Fixed score statement 'n'.
  - Fixed bug in diskin2 leading to infinite loop.
  - Fixed bug causing crossfade noise in hrtfmove.
  - Fixed unlikely buffer overflows in some utilities.
  - Avoid segfault in midicN.
  - Bug in mp3in in skip=0 case fixed.
  - 'r' score statement fixed with respect to macros.
  - sndwarp could segfault.
- System Changes:
  - Preprocessor #if #else #endif working.
  - #includes depth now limited rather than infinite recursion.
  - Really turn off all displays if --nodisplays or -d is used; fixes bug where using -d or --nodisplays would still cause the winFLTK.c csoundModuleInit to setup display callbacks; bug caused with python TK apps and CsoundYield\_FLTK being called.
  - Memory leak in mp3in and mp3len fixed.
- Internal Changes:

- Very, very, very many! And the new parser...

## New in Version 5.15 (December 2011)

- New opcodes:
  - *ftab2tab* opcode.
  - *tab2pvs* opcode.
  - *pvs2tab* opcode.
  - *cpumeter* opcode, (not really new but now available in OSX)
  - *minmax* opcode.
  - (*EXPERIMENTAL*) *ftresize* opcode.
  - (*EXPERIMENTAL*) *ftresizei* opcode.
  - *hrtfearly* opcode.
  - *hrtfreverb* opcode.

### New Gen and Macros

- Code to allow GEN49 to be deferred [NB does not seem to work]
- Modified Opcodes and Gens
  - socksend and sockrecv no longer uses MTFU check and work on Windows
  - mpulse changed so if next event is at negative time use the absolute value
  - serial opcode now runs on Windows as well as Un\*x
  - out, out2, outq, outh, outo outx and out32 are now identical opcodes and will take up to as many arguments as nchnls. This replaces the current remapping of opcodes
  - turnoff2 now polymorphic wrt S and k types (ie accepts instrumnet names)
- Bugs fixed:
  - GEN42 fixed
  - jacko: fixed a segfault removing the unused JackSessionID option
  - doppler memory leak fixed
  - transegr fixed in release mode when skipping most of envelope
  - FLPack now agrees with manual
  - max\_k now agrees with manual

- hrtfreverb fixed
- atsa code now works on Windows in more cases
- tabmorph bug fixed
- fixed problem with user-defined opcodes having no outputs
- Various fixes to \* ... \*/ comments
- System Changes:
  - Various licence issues sorted
  - Loris is no longer part of the Csound tree
  - Memory leaks fixed
  - If no score is given a dummy that runs for over 100 years is created
  - All score processing takes place in memory without temporary files
  - String memory now expandable and no size limitation
  - #if #else #end now in new parser
  - Adjustments to MIDI file precision in output
  - On OSX move from Coreaudio to AuHAL
  - Multicore now safe for ZAK, Channels and modifying tables
  - New coremidi module
  - Virtual Keyboard improved: 1) Dropdown for choosing base octave (the one that starts with the virtual key mapped to physical key Z). Default value is 5 which is backwards compatible. 2) Shift-X mappings which add two octaves to X mappings for a total of 4 octaves playable from the physical keyboard (starting from selected base octave). 3) Control-N / Control-Shift-N mappings to increment / decrement slider for control N. 4) Mouse wheel now controls sliders.
  - tsig type for vectors
  - tsigs and fsigs allowed as arguments in UDOs
  - API: Minor version upped
- Internal Changes:
  - Very, very, very many!
  - :

## New in Version 5.14 (October 2011)

- New opcodes:

- *mp3len* opcode.
- *qnan* opcode.
- *qinf* opcode.
- *exprandi* opcode.
- *cauchyi* opcode.
- *gaussi* opcode.
- *cpumeter* opcode.
- *linsegb* opcode.
- *expsegb* opcode.
- *transegb* opcode.
- *expsegba* opcode.
- *pvsgain* opcode.
- *pvsbufread2* opcode.
- *serial* opcodes.
- *lua opcodes* opcodes.
- *plustab* opcode.
- *multtab* opcode.
- *maxarray* opcode.
- *minarray* opcode.
- *sumarray* opcode.
- *scalearray* opcode.
- New functionality
  - beats processor renamed to csbeats and distributed
  - mkdb utility to provide a catalogue of plugin libraries/opcodes
  - ladspa library build in default system
  - macros are now expanded inside string in the score
  - there in an until .. do .. od looping syntax (in the new parser only)
  - SIGPIPE signals are ignored rather than causing Csound to exit
- It is possible to use vectors of k-rate values, named t-variable. They are initialised to a fixed sizw with init adncan be read with a simple [] syntax. assignment to elements is only via =. There are also a few new opcodes that provide wider functionality.

- Bug fixes and improvements:
  - reading values to fill tables was broken with respect to comments
  - internal error in wii\_data fixed
  - pvsshift fixed
  - jacko fixed
  - gen23 minor fixes
  - wiimote fixed
  - atsaadd fixed
  - compress fixed to work with 0dbfs
  - pvsbufread corrected with respect to position counting
  - tempo opcode fixed
  - CsFileB section in .csd files had a bug, now fixed
  - deferred gen01 tables could have wrong size
  - vbap\_zak made to work(!)
  - fixed memory issue in ATSSinoi
  - various fixes to cscore
  - various fixes to partials and tradsyn
  - transegr could crash in some cases
  - loris opcodes updated to latest version
  - date opcode has new base in some platforms to avoid overflow
  - pvsblur now works over reinit
  - diskin, diskin2 and soundin now can read up to 40 channels
  - prints behaves better with rounding
  - fmpercfl now has working vibrato
  - atreson now has gain parameter at k-rate
  - comb opcode made safe if in and out arguments the same
  - better accuracy in line and expon
  - OSCsend recovers space previously lost
  - OSCsend can send a table as a blob with the T tag -- experimental and untested.
  - lpf18 now has an optional iskip argument

- i() will also accept an i-rate value in which case it is a no-op
- makecsd revised and extended to have options for MIDI and score processing and licenses
- lpanal reworked to remove bugs and oddities
- an issue with noise in alsafixed and a click in portaudio fixed
- portaudio driver changed to be more robust on stop/exit
- Internal Changes:
  - Many many changes to the new parser so it is now operational, but should be used with care
  - The multicore system is distributed in an experimental mode and should be used with great care.
- :
- :

## New in Version 5.13 (January 2011)

- New opcodes:
  - *median* opcode.
  - *filevalid* opcode.
  - *pvstanal*, *pvsawarp*, *temposcals*, *pvslock* spectral processing opcodes.
  - *mincer* opcode
  - *fareylen* sequence opcodes.
- New functionality
  - Real random number generators using /dev/random (Linux only).
  - INF macro added to orchestras; z read as infinity in scores
  - init changed to allow multiple inits in on statement
  - GEN for support of farey sequences
  - *maxalloc*, *cpuprc*, *active* now accept named instruments.
  - If normalisation in pow opcodes is zero treat as 1
  - *inch* can take up to 20 inputs and outputs.
  - *pvscale*, *pvsfoc* and *pvsmix* now have very good spectral envelope preservation modes (1 = filtered cepstrum, 2 = true envelope).
  - *oscill* could be static if the duration was long; now there is a positive minimum increment.
  - GEN49 now uses search paths.
- Bug fixes and improvements:

- Count of lines fixed in orchestras, and \ inside strings
- Fast tab opcodes made safe from crashes
- % in formated printing could crash
- Double free in fgen fixed
- *sndwarp* quietened (gave too many messages)
- gen41 deals with positive probabilities
- *adsynt* reworked removing many bugs
- *adsynt2* phase error fixed
- Bug in max number of gens fixed
- Better checking in grain4
- Better checking in *adsyn*
- modulus was wrong in new parser
- *atonex/tonex* did wrong operation
- *mp3in* could repeat sound at end of file
- *changed* opcode initialised to zero
- Serious bug in *tabmorpha* fixed
- GEN49 has serious bug removed, so no longer incorrect silences.
- *partikkel* opcode: fixed bug in sub-sample grain placement when using grain rate FM
- Internal Changes:
  - In the new parser only there are operator @ and @@ to round up the next integer to a power of 2 or powerof2+1
  - Score sorting made much faster
  - lineto improved
  - Named gens allowed
  - Various printing include instrument name if available
  - Command option to omit loading a library
  - Number of out channels no longer constrained to be number of in
  - Many fixes to new parser
  - More use of Warnings than Messages (allows for them to be switched off)
  - csoundSetMessageCallback reset if callback set to null

## New in Version 5.12 (January 2010)

- New opcodes:
  - *transegr* is a version of the *transeg* opcode which has a release section which is triggered by midi, a *turnoff2* opcode or a negative instrument number *i score event*.
  - *ftgenonce* generates a function table from within an instrument definition, without duplication of data.
  - *passign* allows quick initialization of i-rate variables from p-fields
  - *crossfm* implements crossed fm synthesis.
  - *loopxseg* is like *loopseg* but with exponential envelope.
  - *looptseg* is like *loopseg* but with a flexible envelope like *transeg*
- Bug fixes and improvements:
  - *pvshift* would overwrite in double mode.
  - *pan2* case 3 fixed.
  - *clockon* and *clockoff* now work again.
  - *cross2* and *interp* could have divided by zero
  - linecount for error messages no longer includes text from *.csoundrc*
  - *p5gconnect* changed to use a separate thread to avoid timeout problem.
  - *transeg* checks argument count.
  - *sload* used to be limited to 10 sound fonts and was not policed. Now open-ended.
- Internal Changes:
  - \" allowed as an escape in orchestral strings
  - New parser fixed on optional arguments
  - Better checking of *f* statement with negative number
  - Soundfonts only initialise pitches array once, in the soundfont opcodes.
  - Usual collection of gratuitous minor changes, layout and comments

## New in Version 5.11 (June 2009)

- New opcodes:
  - *mp3in* allows reading of mp3 files directly in the orchestra.

- wiiconnect, wiidata, wiisend, wirange opcodes by john ffitch to receive and send data to a wiimote controller.
- New opcodes to receive data directly from a p5glove by john ffitch *p5gdata*
- *tabsum* sums sections of ftables
- *MixerSetLevel\_i* an init-time only version of *MixerSetLevel*
- *doppler* implements a simulation of the doppler effect.
- *filebit* reports the file depth of a file.
- The new *Signal Flow opcodes* enable the usage of signal flow graphs in Csound.
- New functionality
  - New panning type for pan2 opcode
  - New csd score tag <CsExScore>.
  - New -Ma option for ALSA RT MIDI module which listens to all devices.
  - There is a gen49 to read mp3 files
  - Added rounding bin code to *pvscale*
  - Added non-power-of-2 table support for *fiload* and *ftsave*
  - GEN23 totally rewritten to be more consistent in what constitutes a separator and comments. (Still no /\* \*/ comments)
- Bug fixes and improvements:
  - New examples for pvs opcodes by Joachim Heintz: pvsarp, pvscent, pvsbandp, pvsbandr, pvsbufread, pvsadsyn, pvsynth, pvsblur, pvscale, pvscross, pvsfilter, pvsfreeze, pvshift, pvsmaska, pvsmorph
  - Use of automatic numbering of ftables reuses table numbers
    - seed with positive argument was wrong
    - sprintf with an empty string printed wrong data
    - mute now works with both numeric and named instruments
    - Small fixes in diskin, and in tablexkt
- Internal Changes:
  - SConstruct now builds completely independent shared libraries for Python, Lua, and Java wrappers.
  - New Parser almost usable
  - Redrawing of graphs fixed so that only selected ones get redrawn.
  - RT-alsa more forgiving on near sample rates

- It is possible to have the score generated by an external program rather than using standard score format using <CScore bin="translater"> to call the program translater on the score data
- lpc\_export fixed
- Removed limit on macro names length
- PMAX, the number of arguments to a score event has been reduced by 2, and an overflow system introduced so GENs can have arbitrary numbers of arguments.
- Increased API version to 2.1.
- New API function pointer ldmemfile2withCB() which is a version of ldmemfile() allowing a callback to be set and called exactly once to process the MEMFIL buffer after it is loaded.
- csound->floatsize set; zero in earlier versions
- GetChannelLock added

## New in Version 5.10 (December 2008)

- New functionality
  - New option to listen to all MIDI devices using the portmidi realtime module. To enable listening to all devices use "--rtmidi=portmidi -Ma".
  - Dither on output implemented; rectangular and triangular dither available in some cases
  - *GEN20* type 6 now has option to set variance
- Bug fixes and improvements:
  - Locale set to C numeric to avoid , versus . problems.
  - *diskin* fixed
  - *outo* was broken regarding channel 6
  - *pitchamdf* fixed
  - *zfilter2* initialization fixed
  - *s32b14* fixed
- Fixed other bugs fixed that have not been reported publicly.
- Internal Changes:
  - The major version of the Csound API is increased to 2; affected csound.so as well. This means that Csound 5.10 is incompatible with applications ("front ends", "clients", or "hosts") that were built for Csound 5.08 and earlier and that use API version 1.x. These applications will need to be rebuilt to work with the current and future versions of Csound. Csound front ends written in interpreted languages such as Python or Java may continue to work without modification. It may also be possible to keep both an earlier version of the Csound library and an API 2.0 version on the same machine together so that new and old Csound-based applications can run side-by-side. These changes

do not in any way affect the compatibility of Csound orchestras and scores: all old documents should continue to work as before.

- Time now counted internally in samples, overcoming a longstanding bug with rounding of time to k-rate.
- Many internal changes related to branch prediction. Some opcodes are substantially quicker.
- 

## New in Version 5.09 (October 2008)

- New opcodes:
  - New *vosim* opcode by Rasmus Ekman which recreates the historic VOSIM (VOcal SIMulator) technique.
  - New *dcblock2* opcode by Victor Lazzarini.
  - New Chua's oscillator model: *chuap* by Michael Gogins.
  - New *Linear Algebra* opcodes by Michael Gogins. Standard Linear algebra over real and complex vectors and matrices: elementwise arithmetic, norms, transpose and conjugate, inner products, matrix inverse, LU decomposition, QR decomposition, and QR-based eigenvalue decomposition. Includes copying vectors to and from a-rate signals, function tables, and f-signals.
  - New ambisonic opcodes: *bformdec1* and *bformenc1*. These opcodes deprecate the older *bformdec* and *bformenc*.
  - New Score control opcodes by Victor Lazzarini: *rewindscore* and *setscorepos*.
- New functionality:
  - The *vbap* family of opcodes (*vbap4*, *vbap8*, *vbap16* and *vbapz*) now accept k-rate variables for all their input arguments.
  - New pulseaudio I/O module on Linux.
  - New optional *ienv* parameter to generate envelopes for the soundfont opcodes: *splay*, *splay3*, *sflym* and *splay3m*.
  - Added 'skip normalisation argument' to "tanh" named GEN routine. (See *Named GEN Routines*)
  - Added scheduler priority option on alsal.
- Bug fixes and improvements:
  - Allow scientific notation (as was in csound4!) in *GEN23*.
  - Fixed bug in FLTK initialization. Should make FLTK usage more stable.
  - Error on /\* \*/ comments in orchestra fixed.
  - *poscil* no longer overwrites frequency if variable is shared.
  - *printk* and *printks* check that opcode is initialised.

- Deprecate *soundout* and *soundouts* in favour of *fout*.
- Fixed *space* opcode to accept non-pow-2 (deferred) tables.
- Fixed *pvsmorph* bug.
- Internal Changes:
  - New parser has #include and argumentless macros.
  - Less casting between floats and doubles in float version.
  - Includes experimental multicore support.
  - *buzz* opcode rewritten.
  - Many other internal changes and small bug fixes.

## New in Version 5.08 (February 2008)

- New opcodes:
  - *imagecreate*, *imagesize*, *imagegetpixel*, *imagesetpixel*, *imagesave*, *imagedload* and *imagefree*: New image file processing opcodes by Cesare Marilungo to read/write png images from Csound.
  - *pvsbandp* and *pvsbandr* by John ffitch, which perform band-pass and band-reject filtering in the spectral domain on a pvs signal.
  - New HRTF opcodes by Brian Carty:*hrtfmove*, *hrtfmove2* and *hrtfstat*.
  - New waveshaping opcodes: *powershape*, *polynomial*, *chebyshevpoly*, *pdclip*, *pdhalf*, *pdhalfy*, and *syncphasor*
  - New jack transport control opcode: *jacktransport*
- New functionality
  - Added --csd-line-nums= command line option to select mode for error line reporting.
  - New "no-carry" operator (! ) for score language that prevents implicit carrying of p-fields in i-statements.
  - Added --syntax-check-only commandline flag (exclusive with --i-only)
  - <*CsLicence*> tag for *CSDs*. <*CsLicense*> is accepted as an alternative to <*CsLicence*>.
- Bug fixes and improvements:
  - Changed order of outputs for *hilbert*. This change breaks compatibility with previous versions, but fixes the opcode and now works as documented.
  - Messages about loading opcode plugins modified so can be suppressed with message level flag.
  - Major changes to score error reporting; now accurately reports the line numbers for the chain of inputs for most errors.

- Corrected *pan2* so it agrees with documentation.
- *<CsVersion>* tag works again according to the manual.
- Fixed the { and } score looping statements. Added missing documentation for them and ~, &, |, and # operators in score expressions.
- *hilbert* had its outputs reversed, now correct. Manual example updated.
- Internal Changes:
  - Change to gettext localisation; French and Columbian-Spanish translations available.
  - Internal changes to *partikkel*, interpolation of waveform read and windowing, allowing more precise pitch synchronous granular synthesis. Updated examples for *partikkel*.
  - *pvscale*: Improved algorithm for SDFT case so no amplitude variation.

## New in Version 5.07 (October 2007)

- New opcodes:
  - *pan2*: a stereo panning opcode
  - *cpsmidinn*, *pchmidinn*, *octmidinn*: converters for MIDI note numbers
  - *fluidSetInterpMethod*: interpolation in fluid sound fonts
  - *sflooper*: a soundfont version of *flooper2*
  - *pvsbuffer* and *pvsbufread*: buffering/reading of fsigs for delays/timescale changes.
- New functionality
  - SDFT - the Sliding Discrete Fourier Transform -- added seamlessly to *pvsanal*, etc opcodes if the overlap is less than the ksmpls or less than 10. Some pvsXXX opcodes extended to take a-rate parameters when sliding.
  - New feature (*-O null* / *--logfile=null*) that disables all messages and printing to the console.
- Bug fixes and improvements:
  - *partikkel* -- particle synthesis had an inadvertent bug, now fixed.
  - Closing of MIDI input on Windows(MM) failed; now fixed
  - *fluidEngine* opcode now takes optional number of channels (range 16-256, default to 256) and polyphony (range 16-4096, default to 4096) to use.
  - *atsa* utility safer when given silence.
  - *ATSaddnz*: improved checking.
  - Ambisonics (*bformdec*, *bformenc*) has more options for controlled opposites.

- Bug in *turnoff2* fixed.
- *het\_export*: invalid check caused export to fail.
- Internal Changes:
  - Improved Windows installer.
  - CsoundVST replaced by CsoundAC, that does not depend on the VST SDK headers.
  - Less messages in Windows(MM) startup.
  - P argument type added (k-rate defaults to 1) for opcode in and out types.

## New in Version 5.06 (June 2007)

- New granular opcodes: *partikkel*, *partikkelsync* and *diskgrain*.
- New opcode for event dispatch: *scoreline*.
- Many new opcodes from Gabriel Maldonado's CsoundAV: *hvs1*, *hvs2*, *hvs3*, *vphaseseg*, *inrg*, *outrg*, *lposcila*, *lposcilsa*, *lposcilsa2*, *tabmorph*, *tabmorpha*, *tabmorphi*, *tabmorphak*, *trandom*, *vtable1k*, *slider8table*, *slider16table*, *slider32table*, *slider64table*, *slider8tablef*, *slider16tablef*, *slider32tablef*, *slider64tablef*, *sliderKawai* and the a-rate version of *ctrl7*.
- Also from CsoundAV, many new FLTK widget opcodes: *FLkeyIn*, *FLslidBnk2*, *FLvslidBnk*, *FLvslidBnk2*, *FLmouse*, *FLxyin*, *FLhvsBox*, *FLslidBnkSet*, *FLslidBnkSetk*, *FLslidBnk2Set*, *FLslidBnk2Setk*, *FLslidBnkGetHandle*,
- New pvs opcodes: *pvsdiskin*, *pvsmorph*,
- *eqfil*
- New command line options (*--m-warnings*) to control messages
- csladspa: a CSD to LADSPA plugin kit.
- And many bug fixes including (but not limited to): fixed k-rate version of *system*; fixed scaling problems of *vrandh* and *vrandi*; fixed occasional failure of *turnoff*; fixed OS X bug; fixed *ATScross* and fixed *mod*.

Csound5GUI now works properly on all platforms and csoundapi~ (pd object) has been updated.

# Introduction

Csound is a unit generator-based, user-programmable computer music system. It was originally written by Barry Vercoe at the Massachusetts Institute of Technology in 1984 as the first C language version of this type of software. Since then Csound has received numerous contributions from researchers, programmers, and musicians from around the world.

Around 1991, John ffitch ported Csound to Microsoft DOS. Csound currently runs on many varieties of UNIX and Linux, Microsoft DOS and Windows, all versions of the Macintosh operating system including Mac OS X, and others.

There are newer computer music systems that have graphical patch editors (e.g. Max/MSP, PD, jMax, or Open Sound World), or that use more advanced techniques of software engineering (e.g. Nyquist or SuperCollider). Yet Csound still has the largest and most varied set of unit generators, is the best documented, runs on the most platforms, and is the easiest to extend. It is possible to compile Csound using double-precision arithmetic throughout for superior sound quality. In short, Csound must be considered one of the most powerful musical instruments ever created.

In addition to this "canonical" version of Csound and CsoundAC, there are other versions of Csound and other front ends for Csound, many of which can be found at <http://csound.github.io>.

---

# The Csound Command

The command *csound* is a basic frontend to the system that can be used to generate a sound output from an *orchestra* file and a *score* file (or a unified *csd* file). It is designed to be called from a terminal or DOS window. In addition to it, there are other *front-ends*, which might be simpler to use. The score file can be in one of many different formats, according to user preference. Translation, sorting, and formatting into orchestra-readable numeric text is handled by various preprocessors; all or part of the score is then sent on to the orchestra. Orchestra performance is influenced by *command flags*, which set the level of displays and console reports, specify I/O filenames and sample formats, and declare the nature of real-time sensing and control.

## Order of Precedence

There are five places where options for Csound performance may be set. They are processed in the following order:

1. Csound's own defaults
2. File defined by the CSOUNDRC *environment variable*, or .csoundrc file in the HOME directory
3. A .csoundrc file in the current directory
4. <CsOptions> tag in a .csd file
5. Passed on the Csound *command line*

The later options in the list will override any earlier ones. As of version 5.01 of Csound, sample and control rate override flags (-r and -k) specified anywhere override sr, kr, and ksmps defined in the orchestra header.

## Description of the command syntax

The csound command is followed by a set of *Command Line Flags* and the name of the orchestra (.orc) and score (.sco) files or the *Unified csd file* (containing both orchestra and score) to process. *Command Line Flags* to control input and output configuration may appear anywhere in the command line, either separately or bundled together. A flag taking a Name or Number will find it in that argument, or in the immediately subsequent one. The following are thus equivalent commands:

```
csound -nm3 orchname -Sxxfilename scorename  
csound -n -m 3 orchname -x xfilename -S scorename
```

All flags and names are optional. The default values are:

```
csound -s -otest -b1024 -B1024 -m7 -P128 orchname scorename
```

where *orchname* is a file containing Csound orchestra code, and *scorename* is a file of score data in standard numeric score format, optionally presorted and time-warped. If *scorename* is omitted, there are two default options:

1. if real-time input is expected (e.g. *-L*, *-M*, *-iadc* or *-F*), a dummy score file is substituted consisting of the single statement 'f 0 3600' (i.e. listen for RT input for one hour)
2. else Csound uses the previously processed *score.srt* in the current directory.

Csound reports on the various stages of score and orchestra processing as it executes, performing various syntax and error checks along the way. Once the actual performance has begun, any error messages will derive from either the instrument loader or the unit generators themselves. A CSound command may include any rational combination of flag arguments.

## Running the examples in this manual from the command line

Most of the manual's examples come ready to run without the need of adding any command line flags since they specify options within the csd file's <CsOptions> tag, so you only need to type something like:

```
csound oscil.csd
```

within the examples folder, and realtime audio output should be generated.

# Csound command line

csound

## Description

The *csound* command executes Csound.

## Syntax

```
csound [flags] [orchname] [scorename]  
  
csound [flags] [csdfilename]
```

## Csound command line flags

Listed below are the command line flags available in Csound6 in alphabetical order. Various platform implementations may not react the same way to different flags! You can view the command line flags organized by category in *Command-line Flags (by Category)*.

The command line arguments are of 2 types: *flags* arguments (beginning with a “-”, “--” or “-+”), and *name* arguments (such as filenames). Certain flag arguments take a following name or numeric argument. Flags that start with “--” and “-+” usually take an argument themselves using “=”.

### Command-line Flags

|                               |  |
|-------------------------------|--|
| -@ FILE                       | Provide an extended command-line in file “FILE”  |
| -3, --format=24bit            | Use 24-bit audio samples.  |
| -8, --format=uchar            | Use 8-bit unsigned character audio samples.  |
| --format= <i>type</i>         | Set the audio file output format to one of the formats available in libsndfile. At present the list is aiff, au, avr, caf, flac, htk, ircam, mat4, mat5, MPC, nist, ogg, paf, pvf, raw, sd2, sds, svx, voc, w64, W64, wav, wavex, WVE, xi. Can also be used as -format= <i>type</i> :format or --format=format: <i>type</i> to set both the file type (wav, aiff, etc.) and sample format (short, long, float, etc.) at the same time.   |
| -A, --aiff, --format=aiff     | Write an AIFF format soundfile. Use with the <i>-c</i> , <i>-s</i> , <i>-l</i> , or <i>-f</i> flags.   |
| -a, --format=alaw             | Use a-law audio samples.   |
| -B NUM, -hardwarebufsamps=NUM | Number of audio sample-frames held in the DAC <i>hardware</i> buffer. This is a threshold on which <i>software</i> audio I/O (above) will wait before returning. A small number reduces audio I/O delay; but the value is often hardware limited, and small values will risk data lates. In the case of portaudio output (the default real-time output), the <i>-B</i> parameter (more precisely, <i>-B / sr</i> ) is passed as the “suggested latency” value. Other than that, Csound has no control over how PortAudio interprets the parameter. The default is 1024 |

on Linux, 4096 on Mac OS X and 16384 on Windows.

|                                 |   |
|---------------------------------|---|
| <b>-b NUM, --iobufsamps=NUM</b> | Number of audio sample-frames per sound i/o <i>software</i> buffer. Large is efficient, but small will reduce audio I/O delay and improve the accuracy of the timing of real time events. The default is 256 on Linux, 1024 on MacOS X, and 4096 on Windows. In real-time performance, Csound waits on audio I/O on <i>NUM</i> boundaries. It also processes audio (and polls for other input like MIDI) on orchestra <i>ksmps</i> boundaries. The two can be made synchronous. For convenience, if <i>NUM</i> is negative, the effective value is <i>ksmps</i> * <i>-NUM</i> (audio synchronous with k-period boundaries). With <i>NUM</i> small (e.g. 1) polling is then frequent and also locked to fixed DAC sample boundaries. |
|                                 | Note: if both <i>-iadc</i> and <i>-odac</i> are used at the same time (full duplex real time audio), the <i>-b</i> option should be set to an integer multiple of <i>ksmps</i> .  |
| <b>-C, --cscore</b>             | Use CsScore processing of the scorefile.  |
| <b>-c, --format=schar</b>       | Use 8-bit signed character audio samples.   |
| <b>--csd-line-nums=NUM</b>      | Determines how line numbers are counted and displayed for error messages when processing a Csound Unified Document file (.csd). This flag has no effect if separate orchestra and score files are used. (Csound 5.08 and later). <ul style="list-style-type: none"> <li>• 0 = line numbers are relative to the beginning of the orchestra or score sections of the CSD</li> <li>• 1 = line numbers are relative to the beginning of the CSD file. This is the default as of Csound 5.08.</li> </ul>   |
| <b>-D, --defer-gen1</b>         | Defer GEN01 soundfile loads until performance time.   |
| <b>-d, --nодisplays</b>         | Suppress all displays. See <i>-O</i> if you want to save the log to a file.   |
| <b>-d</b>                       | This option only works from the command line and not from .csound6rc or a CsOptions section of a csd file. It needs to be acted upon before sound proper starts. It is ignored in .csoundrc and CsOptions.  |
| <b>--devices</b>                | Run in daemon mode: do not exit if CSD/orchestra is not given, is empty or does not compile.  |
| <b>--devices[=x]</b>            | Gives a list of available audio devices and then exits.   |
| <b>--displays</b>               | list audio devices (x=out, output devices only; x=in, input; else input and output) and exit.   |
| <b>--default-paths</b>          | Enables displays, reverting the effect of any previous <i>-d</i> flag.  |
| <b>--env:NAME=VALUE</b>         | Reenables adding of directory of CSD/ORC/SCO to search paths, if it has been disabled by a previous <i>--no-default-paths</i> (e.g. in .csoundrc).  |
|                                 | Set environment variable NAME to VALUE. Note: not all envir-  |

onment variables can be set this way, because some are read before parsing the command line. INCDIR, SADIR, *SFDIR*, and *SSDIR* are known to work.

--env:NAME+=VALUE

Append VALUE to ';' separated list of search paths in environment variable NAME (should be INCDIR, SADIR, *SFDIR*, or *SSDIR*). If a file is found in multiple directories, the last will be used.

--expression-opt

*Note that this option has no affect in csound6. In Csound 5 only.*  
Turns on some optimizations in expressions:

- Redundant assignment operations are eliminated whenever possible. This means that for example this line `a1 = a2 + a3` will compile as `a1 Add a2, a3` instead of `#a0 Add a2, a3 a1 = #a0` saving a temporary variable and an opcode call. Less opcode calls result in reduced CPU usage (an average orchestra may compile about 10% faster with --expression-opt, but it depends largely on how many expressions are used, what the control rate is (see also below), etc.; thus, the difference may be less, but also much more).
- number of a- and k-rate temporary variables is significantly reduced. This expression

```
(a1 + a2 + a3 + a4)
```

will compile as

```
#a0 Add a1, a2
#a0 Add #a0, a3
#a0 Add #a0, a4 ; (the result is in #a0)
```

instead of

```
#a0 Add a1, a2
#a1 Add #a0, a3
#a2 Add #a1, a4 ; (the result is in #a2)
```

The advantages of less temporary variables are:

- less cache memory is used, which may improve performance of orchestras with many a-rate expressions and a low control rate (e.g. `ksmps = 100`)
- large orchestras may load faster due to less different identifier names
- index overflow errors (i.e. when messages like this `Case2: idx=-56004 (ffff253c); (short)idx = 9532 (253c)` are printed and odd behavior or a Csound crash occurs) may be fixed, because such errors are triggered by too many different (especially a-rate) variable names in a single instrument.

Note that this optimization (due to technical reasons) is not performed on i-rate temporary variables.

## Warning

When --expression-opt is turned on, it is not allowed to use the i() function with an expression argument, and relying on the value of k-rate expressions at i-time is unsafe.

-F FILE, --midifile=FILE

Read MIDI events from MIDI file *FILE*. The file should have only one track in Csound versions 4.xx and earlier; this limitation is removed in Csound 5.00.

-f, --format=float

Use single-format float audio samples (not playable on some systems, but can be read by -i, *soundin* and *GEN01*)

-G, --postscriptdisplay

Suppress graphics, use PostScript displays instead.

-g, --asciidisplay

Suppress graphics, use ASCII displays instead.

--get-system-sr

prints system sr and exits, requires -o dac.

-H#, --heartbeat=NUM

Print a heartbeat after each soundfile buffer write:

- no NUM, a rotating bar.
- NUM = 1, a rotating bar.
- NUM = 2, a dot (.)
- NUM = 3, filesize in seconds.
- NUM = 4, sound a bell.

-h, --noheader

No header on output soundfile. Don't write a file header, just binary samples.

--help

Display on-line help message.

-I, --i-only

*i-time only*. Allocate and initialize all instruments as per the score, but skip all p-time processing (no k-signals or a-signals, and thus no amplitudes and no sound). Provides a fast validity check of the score pfields and orchestra i-variables. This option is exclusive of the --syntax-check-only flag.

-i FILE, --input=FILE

Input soundfile name. If not a full pathname, the file will be sought first in the current directory, then in that given by the environment variable *SSDIR* (if defined), then by *SFDIR*. The name *stdin* will cause audio to be read from standard input.

The name *devaudio* or *adc* will request sound from the host audio input device. It is possible to select a device number by appending an integer value in the range 0 to 1023, or a device name separated by a : character (e.g. -iadc3, -iadc:hw:1,1). It depends on the host audio interface whether a device number or a name should be used. In the first case, an out of range number usually results in an error and listing the valid device numbers.

The audio coming in using -i can be received using opcodes like

|  |  |
|--|--|
|  | <i>inch.</i>   |
| -+id_artist=string   | (max. length = 200 characters) Artist tag in output soundfile (no spaces)  |
| -+id_comment=string  | (max. length = 200 characters) Comment tag in output soundfile (no spaces)   |
| -+id_copyright=string  | (max. length = 200 characters) Copyright tag in output soundfile (no spaces)   |
| -+id_scopyright=integer  | (Since version 6.05) Simple copyright/licence encoded as an integer. Coding is:  |
| 0: "All rights reserved" (default)   |  |
| 1: "Creative Commons Attribution-NonCommercial-NoDerivatives (CC BY-NC-ND)"              |  |
| 2: "Creative Commons Attribution-NonCommercial-ShareAlike (CC BY-NC-SA)"                 |  |
| 3: "Creative Commons Attribution-NonCommercial (CC BY-NC)"                               |  |
| 4: "Creative Commons Attribution-NoDerivatives (CC BY-ND)"                               |  |
| 5: "Creative Commons Attribution-ShareAlike (CC BY-SA)"                                  |  |
| 6: "Creative Commons Attribution-ShareAlike (CC BY)"                                     |  |
| 7: "Licenced under BSD"  |  |
| -+id_date=string   | .  |
|  | (max. length = 200 characters) Date tag in output soundfile (no spaces)  |
| -+id_software=string   | (max. length = 200 characters) Software tag in output soundfile (no spaces)  |
| -+id_title=string  | (max. length = 200 characters) Title tag in output soundfile (no spaces)   |
| -+ignore_csopts=integer  | If set to 1, Csound will ignore all options specified in the csd file's CsOptions section. See <i>Unified File Format for Orchestras and Scores</i> .  |
| -+input_stream=string  | Pulseaudio input stream name.  |
| -J, --ircam, --format=ircam  | Write an IRCAM format soundfile.   |
| -j NUM   | Make <i>NUM</i> processes available for rendering. This is only advantageous if the number of processors on the computer is more than the number of requested processes. It also may slow rendering down if ksmpls is too small. |
| -+jack_client=[client_name]  | The client name used by Csound, defaults to 'csound5'. If multiple instances of Csound connect to the JACK server, different client names need to be used to avoid name conflicts. (Linux and Mac OS X only)                     |
| -+jack_inportname=[input port name prefix], -+jack_outportname=[output port name prefix] | Name prefix of Csound JACK input/output ports; the default is 'input' and 'output'. The actual port name is the channel number appended to the name prefix. (Linux and Mac OS X only)  |
|  | Example: with the above default settings, a stereo orchestra will create these ports in full duplex operation:   |

csound5:input1

(record left)

|   |  |
|---|--|
| <pre>csound5:input2 csound5:output1 csound5:output2</pre> | <pre>(record right) (playback left) (playback right)</pre> |
|---|--|

|                                     |   |
|-------------------------------------|---|
| <b>-K, --nopeaks</b>                | Do not generate any PEAK chunks.  |
| <b>-k NUM, --control-rate=NUM</b>   | Override the control rate ( <i>KR</i> ) supplied by the orchestra.  |
| <b>-L DEVICE, --score-in=DEVICE</b> | Read line-oriented real-time score events from device <i>DEVICE</i> . The name <i>stdin</i> will permit score events to be typed at your terminal, or piped from another process. Each line-event is terminated by a carriage-return. Events are coded just like those in a <i>standard numeric score</i> , except that an event with p2=0 will be performed immediately, and an event with p2=T will be performed T seconds after arrival. Events can arrive at any time, and in any order. The score <i>carry</i> feature is legal here, as are held notes (p3 negative) and string arguments, but ramps and <i>pp</i> or <i>np</i> references are not. |

## Note

The **-L** flag is only valid on \*NIX systems which have pipes. It doesn't work on Windows.

|                                       |  |
|---------------------------------------|--|
| <b>-l, --format=long</b>              | Use long integer audio samples.  |
| <b>-M DEVICE, -midi-device=DEVICE</b> | Read MIDI events from device <i>DEVICE</i> . If using ALSA MIDI (-+rtmidi=alsa), devices are selected by name and not number. So, you need to use an option like <b>-M hw:CARD,DEVICE</b> where CARD and DEVICE are the card and device numbers (e.g. <b>-M hw:1,0</b> ). In the case of PortMidi and MME, <i>DEVICE</i> should be a number, and if it is out of range, an error occurs and the valid device numbers are printed. When using PortMidi, you can use ' <b>-Ma</b> ' to enable all devices. This is also convenient when you don't have devices as it will not generate an error. |

**-m NUM, --messagelevel=NUM** Message level for standard (terminal) output. Takes the *sum* of any of the following values:

- 1 = note amplitude messages
- 2 = samples out of range message
- 4 = warning messages
- 128 = print benchmark information

And exactly one of these to select note amplitude format:

- 0 = raw amplitudes, no colours
- 32 = dB, no colors
- 64 = dB, out of range highlighted with red
- 96 = dB, all colors
- 256 = raw, out of range highlighted with red

- 512 = raw, all colours

The default is 135 (128+4+2+1), which means all messages, raw amplitude values, and printing elapsed time at the end of performance. The coloring of raw amplitudes was introduced in version 5.04.

--mamps=NUM

Message level for amplitudes on standard (terminal) output.

- 0 = no note amplitude messages
- 1 = note amplitude messages

--m-range=NUM

Message level for out of range messages on standard (terminal) output.

- 0 = no samples out of range message
- 1 = samples out of range message

--m-warnings=NUM

Message level for warnings on standard (terminal) output.

- 0 = no warning messages
- 1 = warning messages

--m-dB=NUM

Message level for amplitude format on standard (terminal) output.

- 0 = absolute amplitude messages
- 1 = dB amplitude messages

--m-colours=NUM

Message level for amplitude format on standard (terminal) output.

- 0 = no colouring of amplitude messages
- 1 = colouring of amplitude messages

--m-benchmarks=NUM

Message level for benchmark information on standard (terminal) output.

- 0 = no benchark numbers
- 1 = print benchark numbers

-+max\_str\_len=integer

(min: 10, max: 10000) Maximum length of string variables + 1; defaults to 256 allowing a length of 255 characters. The length of string constants is not limited by this parameter.

--midi-devices[=x]

list midi devices (x=out, output devices only; x=in, input; else input and output) and exit.

--midi-key=N

Route MIDI note on message key number to pfield N as MIDI value [0-127].

--midi-key-cps=N

Route MIDI note on message key number to pfield N as cycles per second.

--midi-key-oct=N

Route MIDI note on message key number to pfield N as linear octave.

|                         |   |
|-------------------------|---|
| --midi-key-pch=N        | Route MIDI note on message key number to pfield N as oct.pch (pitch class).   |
| --midi-velocity=N       | Route MIDI note on message velocity number to pfield N as MIDI value [0-127].   |
| --midi-velocity-amp=N   | Route MIDI note on message velocity number to pfield N as amplitude [0-0dbFS].  |
| --midioutfile=FILENAME  | Save MIDI output to a file (Csound 5.00 and later only).  |
| -+msg_color=boolean     | Enable message attributes (colors etc.); might need to be disabled on some terminals which print strange characters instead of modifying text attributes. default: true.  |
| -+mute_tracks=string    | (max. length = 255 characters) Ignore events (other than tempo changes) in MIDI file tracks defined by pattern (for example, -+mute_tracks=00101 will mute the third and fifth tracks).   |
| -N, --notify            | Notify (ring the bell) when score or MIDI track is done.  |
| -n, --nosound           | No sound. Do all processing, but bypass writing of sound to disk. This flag does not change the execution in any other way.   |
| --num-threads=NUM       | Make <i>NUM</i> processes available for rendering. This is only advantageous if the number of processors on the computer is more than the number of requested processes. It also may slow rendering down if ksmpls is too small.  |
| --no-default-paths      | Disables adding of directory of CSD/ORC/SCO to search paths.  |
| --no-expression-opt     | Disables expression optimization.   |
| -O FILE, --logfile=FILE | Log output to file <i>FILE</i> . If <i>FILE</i> is null (i.e. <i>-O null</i> or <i>-logfile=null</i> ) all printing of messages to the console is disabled.   |
| -o FILE, --output=FILE  | Output soundfile name. If not a full pathname, the soundfile will be placed in the directory given by the environment variable <i>SF-DIR</i> (if defined), else in the current directory. The name <i>stdout</i> will cause audio to be written to standard output, while <i>null</i> results in no sound output similarly to the <i>-n</i> flag. If no name is given, the default name will be <i>test</i> . |

### Note

This option only works from the command line and not from .csound6rc or a CsOptions section of a csd file. It needs to be acted upon before sound proper starts. It is ignored in .csoundrc and CsOptions.

The name *devaudio* or *dac* (you can use *-odac* or *-o dac*) will request writing sound to the host audio output device. It is possible to select a device number by appending an integer value in the range 0 to 1023, or a device name separated by a : character (e.g. *-odac3*, *-odac:hw:1,1*). It depends on the host audio interface whether a device number or a name should be used. In the first case, an out of range number usually results in an error and listing the valid device numbers.

|                               |   |
|-------------------------------|---|
| --ogg                         | Set output file format to ogg. (csound 5.18 and later)  |
| --omacro:XXX=YYY              | Set orchestra macro XXX to value YYY  |
| --opcode-lib=LIBNAME          | Load plugin library <i>LIBNAME</i> .  |
| --orc orcname                 | Set the argument as the orchestra file. Used when not score is required. (Csound 5.18 and later).   |
| --ksmps=N                     | Set ksmmps override to N (6.05 and later).  |
| -+output_stream=string        | Pulseaudio output stream name.  |
| --port=N                      | Set UDP port on which to listen instruments/orchestra code (implies --daemon)   |
| -Q DEVICE                     | Enables MIDI OUT operations to device id <i>DEVICE</i> . This flag allows parallel MIDI OUT and DAC performance. Unfortunately the real-time timing implemented in Csound is completely managed by DAC buffer sample flow. So MIDI OUT operations can present some time irregularities. These irregularities can be reduced by using a lower value for the -b flag.<br><br>If using ALSA MIDI (-+rtmidi=alsa), devices are selected by name and not number. So, you need to use an option like -Q hw:CARD,DEVICE where CARD and DEVICE are the card and device numbers (e.g. -Q hw:1,0). In the case of PortMidi and MME, DEVICE should be a number, and if it is out of range, an error occurs and the valid device numbers are printed. |
| -R, --rewrite                 | Continually rewrite the header while writing the soundfile (WAV/AIFF).  |
| -r NUM, --sample-rate=NUM     | Override the sampling rate ( <i>SR</i> ) supplied by the orchestra.   |
| -+raw_controller_mode=boolean | Disable special handling of MIDI controllers like sustain pedal, all notes off etc., allowing the use of all the 128 controllers for any purpose. This will also set the initial value of all controllers to zero. Default: no.   |
| --realtime                    | realtime priority mode is switched on which the following effects:<br><br>1. all opcode audio file reading/writing is handled asynchronously by a separate thread.<br><br>2. all init-pass operations are also performed asynchronously.  |
| -+rtaudio=string              | (max. length = 20 characters) Real time audio module name. The default is PortAudio. Also available, depending on platform and build options: Linux: alsa, jack; Windows: mme; Mac OS X: CoreAudio. In addition, null can be used on all platforms, to disable the use of any real time audio plugin.   |
| -+rtmidi=string               | (max. length = 20 characters) Real time MIDI module name. Defaults to PortMidi, other options (depending on build options): Linux: alsa; Windows: mme, winmm. In addition, null can be used on all platforms, to disable the use of any real time MIDI plugin.  |

|                               |   |
|-------------------------------|---|
|                               | ALSA MIDI devices are selected by name and not number. So, you need to use an option like -M hw:CARD,DEVICE where CARD and DEVICE are the card and device numbers (e.g. -M hw:1,0).   |
| -s, --format=short            | Use short integer audio samples.  |
| --sample-accurate             | Start and stop instances of instruments at the nearest sample to the requested time. This is in contrast to traditional Csound which rounds the times to the nearest k-cycle. Note that this does not work with tied notes.   |
| --sched                       | <i>Linux only</i> . Use real-time scheduling and lock memory. (Also requires -d and either -o dac or -o devaudio). See also --sched=N below.  |
| --sched=N                     | <i>Linux only</i> . Same as --sched, but allows specifying a priority value: if N is positive (in the range 1 to 99) the scheduling policy SCHED_RR will be used with a priority of N; otherwise, SCHED_OTHER is used with the nice level set to N. Can also be used in the format --sched=N,MAXCPU,TIME to enable the use of a "watchdog" thread that terminates Csound if the average CPU usage exceeds MAXCPU percents over a period of TIME seconds (new in Csound 5.00). |
| +server=string                | Pulseaudio server name.   |
| +skip_seconds=float           | (min: 0) Start playback at the specified time (in seconds), skipping earlier events in the score and MIDI file.   |
| --smacro:XXX=YYY              | Set score macro XXX to value YYY  |
| --strset                      | <i>Csound 5</i> . The --strset option allows setting strset string values from the command line, in the format '-strsetN=VALUE'. It is useful for passing parameters to the orchestra (e.g. file names).  |
| --syntax-check-only           | Causes Csound to exit immediately after the orchestra and score parsers finish checking the syntax of the input files and before the orchestra performs the score. This option is exclusive of the -i-only flag. (Csound 5.08 and later).   |
| -T, --terminate-on-midi       | Terminate the performance when the end of MIDI file is reached.   |
| -t0, --keep-sorted-score      | Prevents Csound from deleting the sorted score file, score.srt, upon exit.  |
| -t NUM, --tempo=NUM           | Use the uninterpreted beats of <i>score.srt</i> for this performance, and set the initial tempo at <i>NUM</i> beats per minute. When this flag is set, the tempo of score performance is also controllable from within the orchestra. WARNING: this mode of operation is experimental and may be unreliable.  |
| -U UTILITY, --utility=UTILITY | Invoke the utility program <i>UTILITY</i> . Use any invalid name to list the available utilities.   |
| -u, --format=ulaw             | Use u-law audio samples.  |
| --vbr-quality=X               | Set variable bit-rate quality for output to ogg. (Csound 6.03 and   |

|  |  |
|--|--|
|  | later).  |
| -v, --verbose                              | Verbose translate and run. Prints details of orch translation and performance, enabling errors to be more clearly located.   |
| -W, --wave, --format=wave                  | Write a WAV format soundfile.  |
| -x FILE, --extract-score=FILE              | Extract a portion of the sorted score, score.srt, using the extract file <i>FILE</i> (see <i>Extract</i> ).  |
| -Z, --dither                               | Switch on dithering of audio conversion from internal floating point to 32, 16 and 8-bit formats. The default form of the dither is triangular.  |
| -Z, --dither--triangular, -dither--uniform | Switch on dithering of audio conversion from internal floating point to 32, 16 and 8-bit formats. In the case of -Z the next digit should be a 1 (for triangular) or a 2 (for uniform). The exact interpretation depends on the output system.             |
| -z NUM, --list-opcodesNUM                  | List opcodes in this version: <ul style="list-style-type: none"><li>• no NUM, just show names</li><li>• NUM = 0, just show names</li><li>• NUM = 1, show arguments to each opcode using the format &lt;opname&gt; &lt;outargs&gt; &lt;inargs&gt;</li></ul> |

## Command-line Flags (by Category)

Listed below are the command line available in Csound5 organized by categories. Various platform implementations may not react the same way to different flags!

You can view the command line flags organized alphabetically in *Command-line Flags (Alphabetically)*.

The format of a command is either:

csound [flags] [orchname] [scorename]  
or

csound [flags] [csdfilename]

where the arguments are of 2 types: *flags* arguments (beginning with a “-”, “--” or “-+”), and *name* arguments (such as filenames). Certain flag arguments take a following name or numeric argument. Flags that start with “--” and “-+” usually take an argument themselves using “=”.

### Audio File Ouput

|                           |  |
|---------------------------|--|
| -3, --format=24bit        | Use 24-bit audio samples.  |
| -8, --format=uchar        | Use 8-bit unsigned character audio samples.  |
| -A, --aiff, --format=aiff | Write an AIFF format soundfile. Use with the <i>-c</i> , <i>-s</i> , <i>-l</i> , or <i>-f</i> flags. |
| -a, --format=alaw         | Use a-law audio samples.   |

|                             |  |
|-----------------------------|--|
| -c, --format=schar          | Use 8-bit signed character audio samples.  |
| -f, --format=float          | Use single-format float audio samples (not playable on some systems, but can be read by <i>-i, soundin</i> and <i>GEN01</i> )  |
| --format= <i>type</i>       | Set the audio file output format to one of the formats available in libsndfile. At present the list is aiff, au, avr, caf, flac, htk, ircam, mat4, mat5, nis, paf, pvf, raw, sd2, sds, svx, voc, w64, wav, wavex and xi. Can also be used as --format= <i>type:format</i> or -format=format: <i>type</i> to set both the file type (wav, aiff, etc.) and sample format (short, long, float, etc.) at the same time.  |
| -h, --noheader              | No header on output soundfile. Don't write a file header, just binary samples.   |
| -i FILE, --input=FILE       | Input soundfile name. If not a full pathname, the file will be sought first in the current directory, then in that given by the environment variable <i>SSDIR</i> (if defined), then by <i>SFDIR</i> . The name <i>stdin</i> will cause audio to be read from standard input.  |
|                             | The name <i>devaudio</i> or <i>adc</i> will request sound from the host audio input device. It is possible to select a device number by appending an integer value in the range 0 to 1023, or a device name separated by a : character. It depends on the host audio interface whether a device number or a name should be used. In the first case, an out of range number usually results in an error and listing the valid device numbers.   |
|                             | The audio coming in using <i>-i</i> can be received using opcodes like <i>inch</i> .   |
| -J, --ircam, --format=ircam | Write an IRCAM format soundfile.   |
| -K, --nopeaks               | Do not generate any PEAK chunks.   |
| -l, --format=long           | Use long integer audio samples.  |
| -n, --nosound               | No sound. Do all processing, but bypass writing of sound to disk. This flag does not change the execution in any other way.  |
| -o FILE, --output=FILE      | Output soundfile name. If not a full pathname, the soundfile will be placed in the directory given by the environment variable <i>SFDIR</i> (if defined), else in the current directory. The name <i>stdout</i> will cause audio to be written to standard output, while <i>null</i> results in no sound output similarly to the <i>-n</i> flag. If no name is given, the default name will be <i>test</i> .   |
|                             | The name <i>dac</i> or <i>devaudio</i> (you can use <i>-odac</i> or <i>-o dac</i> ) will request writing sound to the host audio output device. It is possible to select a device number by appending an integer value in the range 0 to 1023, or a device name separated by a : character. It depends on the host audio interface whether a device number or a name should be used. In the first case, an out of range number usually results in an error and listing the valid device numbers. |
| --ogg                       | Set output file format to ogg. (Csound 5.18 and later).  |
| --vbr-quality=X             | Set variable bit-rate quality for output to ogg. (Csound 6.03 and later).  |

|  |  |
|--|--|
| -R, --rewrite                              | Continually rewrite the header while writing the soundfile (WAV/AIFF).   |
| -s, --format=short                         | Use short integer audio samples.   |
| -u, --format=ulaw                          | Use u-law audio samples.   |
| -W, --wave, --format=wave                  | Write a WAV format soundfile.  |
| -Z, --dither                               | Switch on dithering of audio conversion from internal floating point to 32, 16 and 8-bit formats. The default form of the dither is triangular.  |
| -Z, --dither--triangular, -dither--uniform | Switch on dithering of audio conversion from internal floating point to 32, 16 and 8-bit formats. In the case of -Z the next digit should be a 1 (for triangular) or a 2 (for uniform). The exact interpretation depends on the output system. |

## Output File Id tags

|                         |   |
|-------------------------|---|
| -+id_artist=string      | (max. length = 200 characters) Artist tag in output soundfile (no spaces)   |
| -+id_comment=string     | (max. length = 200 characters) Comment tag in output soundfile (no spaces)  |
| -+id_copyright=string   | (max. length = 200 characters) Copyright tag in output soundfile (no spaces)  |
| -+id_scopyright=integer | (Single version 6.05) Simple copyright/licence encoded as an integer. Coding is:<br><br>0: "All rights reserved" (default)<br>1: "Creative Commons Attribution-NonCommercial-NoDerivatives (CC BY-NC-ND)"<br>2: "Creative Commons Attribution-NonCommercial-ShareAlike (CC BY-NC-SA)"<br>3: "Creative Commons Attribution-NonCommercial (CC BY-NC)"<br>4: "Creative Commons Attribution-NoDerivatives (CC BY-ND)"<br>5: "Creative Commons Attribution-ShareAlike (CC BY-SA)"<br>6: "Creative Commons Attribution-ShareAlike (CC BY)"<br>7: "Licenced under BSD" |
| -+id_date=string        | (max. length = 200 characters) Date tag in output soundfile (no spaces)   |
| -+id_software=string    | (max. length = 200 characters) Software tag in output soundfile (no spaces)   |
| -+id_title=string       | (max. length = 200 characters) Title tag in output soundfile (no spaces)  |

## Realtime Audio Input/Output

**-input=adc[DEVICE]**

The name *devaudio* or *adc* will request sound from the host audio input device. It is possible to select a device number by appending an integer value in the range 0 to 1023, or a device name separated by a : character (e.g. -iadc3, -iadc:hw:1,1). It depends on the host audio interface whether a device number or a name should be used. In the first case, an out of range number usually results in an error and listing the valid device numbers.

**-o dac[DEVICE], -output=dac[DEVICE]**

The name *dac* or *devaudio* (you can use *-odac* or *-o dac*) will request writing sound to the host audio output device. It is possible to select a device number by appending an integer value in the range 0 to 1023, or a device name separated by a : character (e.g. -odac3, -odac:hw:1,1). It depends on the host audio interface whether a device number or a name should be used. In the first case, an out of range number usually results in an error and listing the valid device numbers.

**+rtaudio=string**

(max. length = 20 characters) Real time audio module name. The default is PortAudio (all platforms). Also available, depending on platform and build options: Linux: alsa, jack; Windows: mme; Mac OS X: CoreAudio. In addition, null can be used on all platforms, to disable the use of any real time audio plugin.

**--realtime**

realtime priority mode is switched on which the following effects:

1. all opcode audio file reading/writing is handled asynchronously by a separate thread.
2. all init-pass operations are also performed asynchronously.

**+server=string**

Pulseaudio server name.

**+output\_stream=string**

Pulseaudio output stream name.

**+input\_stream=string**

Pulseaudio input stream name.

**+jack\_client=[client\_name]**

The client name used by Csound, defaults to 'csound5'. If multiple instances of Csound connect to the JACK server, different client names need to be used to avoid name conflicts. (Linux and Mac OS X only)

**+jack\_inportname=[input port name prefix], -+jack\_outportname=[output port name prefix]**

Name prefix of Csound JACK input/output ports; the default is 'input' and 'output'. The actual port name is the channel number appended to the name prefix. (Linux and Mac OS X only)

Example: with the above default settings, a stereo orchestra will create these ports in full duplex operation:

```
csound5:input1          (record left)
csound5:input2          (record right)
csound5:output1         (playback left)
csound5:output2         (playback right)
```

## MIDI File Input/Ouput

**--devices[=x]**

list audio devices (x=out, output devices only; x=in, input; else in-

|                              |   |
|------------------------------|---|
|                              | put and output) and exit.   |
| -F FILE, --midifile=FILE     | Read MIDI events from MIDI file <i>FILE</i> . The file should have only one track in Csound versions 4.xx and earlier; this limitation is removed in Csound 5.00.   |
| --midioutfile=FILENAME       | Save MIDI output to a file (Csound 5.00 and later only).  |
| +mute_tracks=string          | (max. length = 255 characters) Ignore events (other than tempo changes) in MIDI file tracks defined by pattern (for example, +mute_tracks=00101 will mute the third and fifth tracks).  |
| +raw_controller_mode=boolean | Disable special handling of MIDI controllers like sustain pedal, all notes off etc., allowing the use of all the 128 controllers for any purpose. This will also set the initial value of all controllers to zero. Default: no. |
| +skip_seconds=float          | (min: 0) Start playback at the specified time (in seconds), skipping earlier events in the score and MIDI file.   |
| -T, --terminate-on-midi      | Terminate the performance when the end of MIDI file is reached.   |

## MIDI Realtime Input/Ouput

|                                     |  |
|-------------------------------------|--|
| -M DEVICE, -<br>-midi-device=DEVICE | Read MIDI events from device <i>DEVICE</i> . If using ALSA MIDI (+rtmidi=alsa), devices are selected by name and not number. So, you need to use an option like -M hw:CARD,DEVICE where CARD and DEVICE are the card and device numbers (e.g. -M hw:1,0). In the case of PortMidi and MME, DEVICE should be a number, and if it is out of range, an error occurs and the valid device numbers are printed. When using PortMidi, you can use '-Ma' to enable all devices. This is also convenient when you don't have devices as it will not generate an error. |
| --midi-key=N                        | Route MIDI note on message key number to pfield N as MIDI value [0-127].   |
| --midi-key-cps=N                    | Route MIDI note on message key number to pfield N as cycles per second.  |
| --midi-key-oct=N                    | Route MIDI note on message key number to pfield N as linear octave.  |
| --midi-key-pch=N                    | Route MIDI note on message key number to pfield N as oct.pch (pitch class).  |
| --midi-velocity=N                   | Route MIDI note on message velocity number to pfield N as MIDI value [0-127].  |
| --midi-velocity-amp=N               | Route MIDI note on message velocity number to pfield N as amplitude [0-0dbFS].   |
| --midioutfile=FILENAME              | Save MIDI output to a file (Csound 5.00 and later only).   |
| +rtmidi=string                      | (max. length = 20 characters) Real time MIDI module name. Defaults to PortMidi, other options (depending on build options):  |

Linux: alsa; Windows: mme, winmm. In addition, null can be used on all platforms, to disable the use of any real time MIDI plugin.

ALSA MIDI devices are selected by name and not number. So, you need to use an option like -M hw:CARD,DEVICE where CARD and DEVICE are the card and device numbers (e.g. -M hw:1,0).

**-Q DEVICE**

Enables MIDI OUT operations to device id *DEVICE*. This flag allows parallel MIDI OUT and DAC performance. Unfortunately the real-time timing implemented in Csound is completely managed by DAC buffer sample flow. So MIDI OUT operations can present some time irregularities. These irregularities can be reduced by using a lower value for the *-b* flag.

If using ALSA MIDI (-+rtmidi=alsa), devices are selected by name and not number. So, you need to use an option like -Q hw:CARD,DEVICE where CARD and DEVICE are the card and device numbers (e.g. -Q hw:1,0). In the case of PortMidi and MME, DEVICE should be a number, and if it is out of range, an error occurs and the valid device numbers are printed.

## Display

**--csd-line-nums=NUM**

Determines how line numbers are counted and displayed for error messages when processing a Csound Unified Document file (.csd). This flag has no effect if separate orchestra and score files are used. (Csound 5.08 and later).

- 0 = line numbers are relative to the beginning of the orchestra or score sections of the CSD
- 1 = line numbers are relative to the beginning of the CSD file. This is the default as of Csound 5.08.

**-d, --nodisplays**

Suppress all displays. See *-O* if you want to save the log to a file.

**Note**

This option only works from the command line and not from .csound6rc or a CsOptions section of a csd file. It needs to be acted upon before sound proper starts. It is ignored in .csoundrc and CsOptions.

**--displays**

Enables displays, reverting the effect of any previous *-d* flag.

**-G, --postscriptdisplay**

Suppress graphics, use PostScript displays instead.

**-g, --asciidisplay**

Suppress graphics, use ASCII displays instead.

**-H#, --heartbeat=NUM**

Print a heartbeat after each soundfile buffer write:

- no NUM, a rotating bar.
- NUM = 1, a rotating bar.

- NUM = 2, a dot (.)
- NUM = 3, filesize in seconds.
- NUM = 4, sound a bell.

**-m NUM, --messagelevel=NUM** Message level for standard (terminal) output. Takes the *sum* of any of the following values:

- 1 = note amplitude messages
  - 2 = samples out of range message
  - 4 = warning messages
  - 128 = print benchmark information
- And exactly one of these to select note amplitude format:

- 0 = raw amplitudes, no colours
- 32 = dB, no colors
- 64 = dB, out of range highlighted with red
- 96 = dB, all colors
- 256 = raw, out of range highlighted with red
- 512 = raw, all colours

The default is 135 (128+4+2+1), which means all messages, raw amplitude values, and printing elapsed time at the end of performance. The coloring of raw amplitudes was introduced in version 5.04

**--mamps=NUM** Message level for amplitudes on standard (terminal) output.

- 0 = no note amplitude messages
- 1 = note amplitude messages

**--m-range=NUM** Message level for out of range messages on standard (terminal) output.

- 0 = no samples out of range message
- 1 = samples out of range message

**--m-warnings=NUM** Message level for warnings on standard (terminal) output.

- 0 = no warning messages
- 1 = warning messages

**--m-dB=NUM** Message level for amplitude format on standard (terminal) output.

- 0 = absolute amplitude messages
- 1 = dB amplitude messages

|                           |  |
|---------------------------|--|
| --m-colours=NUM           | Message level for amplitude format on standard (terminal) output.  |
|                           | <ul style="list-style-type: none"><li>• 0 = no colouring of amplitude messages</li><li>• 1 = colouring of amplitude messages</li></ul>   |
| --m-benchmarks=NUM        | Message level for benchmark information on standard (terminal) output.   |
|                           | <ul style="list-style-type: none"><li>• 0 = no benchmark numbers</li><li>• 1 = print benchmark numbers</li></ul>   |
| -+msg_color=boolean       | Enable message attributes (colors etc.); might need to be disabled on some terminals which print strange characters instead of modifying text attributes. default: true.   |
| -v, --verbose             | Verbose translate and run. Prints details of orch translation and performance, enabling errors to be more clearly located.   |
| -z NUM, --list-opcodesNUM | List opcodes in this version: <ul style="list-style-type: none"><li>• no NUM, just show names</li><li>• NUM = 0, just show names</li><li>• NUM = 1, show arguments to each opcode using the format &lt;opname&gt; &lt;outargs&gt; &lt;inargs&gt;</li></ul> |

## Performance Configuration and Control

|                               |   |
|-------------------------------|---|
| -B NUM, -hardwarebufsamps=NUM | Number of audio sample-frames held in the DAC <i>hardware</i> buffer. This is a threshold on which <i>software</i> audio I/O (above) will wait before returning. A small number reduces audio I/O delay; but the value is often hardware limited, and small values will risk data lates. In the case of portaudio output (the default real-time output), the -B parameter (more precisely, -B / sr) is passed as the "suggested latency" value. Other than that, Csound has no control over how PortAudio interprets the parameter. The default is 1024 on Linux, 4096 on Mac OS X and 16384 on Windows.  |
| -b NUM, --iobufsamps=NUM      | Number of audio sample-frames per sound i/o <i>software</i> buffer. Large is efficient, but small will reduce audio I/O delay and improve the accuracy of the timing of real time events. The default is 256 on Linux, 1024 on Mac OS X, and 4096 on Windows. In real-time performance, Csound waits on audio I/O on <i>NUM</i> boundaries. It also processes audio (and polls for other input like MIDI) on orchestra <i>ksmps</i> boundaries. The two can be made synchronous. For convenience, if <i>NUM</i> is negative, the effective value is <i>ksmps</i> * - <i>NUM</i> (audio synchronous with k-period boundaries). With <i>NUM</i> small (e.g. 1) polling is then frequent and also locked to fixed DAC sample boundaries. |

Note: if both -iadc and -odac are used at the same time (full duplex real time audio), the -b option should be set to an integer multiple of *ksmps*.

**-d** Run in daemon mode: do not exit if CSD/orchestra is not given, is empty or does not compile.

**-k NUM, --control-rate=NUM** Override the control rate (*KR*) supplied by the orchestra.

**-L DEVICE, --score-in=DEVICE** Read line-oriented real-time score events from device *DEVICE*. The name *stdin* will permit score events to be typed at your terminal, or piped from another process. Each line-event is terminated by a carriage-return. Events are coded just like those in a *standard numeric score*, except that an event with *p2=0* will be performed immediately, and an event with *p2=T* will be performed *T* seconds after arrival. Events can arrive at any time, and in any order. The score *carry* feature is legal here, as are held notes (*p3* negative) and string arguments, but ramps and *pp* or *np* references are not.

## Note

The **-L** flag is only valid on \*NIX systems which have pipes. It doesn't work on Windows.

**--omacro:XXX=YYY**

Set orchestra macro XXX to value YYY

**--port=N**

Set UDP port on which to listen instruments/orchestra code (implies **--daemon**)

**-r NUM, --sample-rate=NUM**

Override the sampling rate (*SR*) supplied by the orchestra.

**--sample-accurate**

Start and stop instances of instruments at the nearest sample to the requested time. This is in contrast to traditional Csound which rounds the times to the nearest k-cycle. Note that this does not work with tied notes.

**--sched**

*Linux only.* Use real-time scheduling and lock memory. (Also requires **-d** and either **-o dac** or **-o devaudio**). See also **--sched=N** below.

**--sched=N**

*Linux only.* Same as **--sched**, but allows specifying a priority value: if N is positive (in the range 1 to 99) the scheduling policy SCHED\_RR will be used with a priority of N; otherwise, SCHED\_OTHER is used with the nice level set to N. Can also be used in the format **--sched=N,MAXCPU,TIME** to enable the use of a "watchdog" thread that terminates Csound if the average CPU usage exceeds MAXCPU percents over a period of TIME seconds (new in Csound 5.00).

**--smacro:XXX=YYY**

Set score macro XXX to value YYY

**--strset**

*Csound 5.* The **--strset** option allows setting strset string values from the command line, in the format '**-strsetN=VALUE**'. It is useful for passing parameters to the orchestra (e.g. file names).

**-+skip\_seconds=float**

(min: 0) Start playback at the specified time (in seconds), skipping earlier events in the score and MIDI file.

**-t NUM, --tempo=NUM**

Use the uninterpreted beats of *score.srt* for this performance, and set the initial tempo at *NUM* beats per minute. When this flag is

set, the tempo of score performance is also controllable from within the orchestra. WARNING: this mode of operation is experimental and may be unreliable.

**-j NUM, --num-threads=NUM**

Make *NUM* processes available for rendering. This is only advantageous if the number of processors on the computer is more than the number of requested processes. It also may slow rendering down if *ksmps* is too small.

## Miscellaneous

**-@ FILE**

Provide an extended command-line in file “FILE”

**-C, --cscore**

Use Csore processing of the scorefile.

**--default-paths**

Reenables adding of directory of CSD/ORC/SCO to search paths, if it has been disabled by a previous *--no-default-paths* (e.g. in *.csoundrc*).

**-D, --defer-gen1**

Defer GEN01 soundfile loads until performance time.

**--env:NAME=VALUE**

Set environment variable NAME to VALUE. Note: not all environment variables can be set this way, because some are read before parsing the command line. INCDIR, SADIR, SFDIR, and SS-DIR are known to work.

**--env:NAME+=VALUE**

Append VALUE to ';' separated list of search paths in environment variable NAME (should be INCDIR, SADIR, SFDIR, or SS-DIR). If a file is found in multiple directories, the last will be used.

**--expression-opt**

*Note that this option has no affect in csound6. In Csound 5 only.*  
Turns on some optimizations in expressions:

- Redundant assignment operations are eliminated whenever possible. This means that for example this line *a1 = a2 + a3* will compile as *a1 Add a2, a3* instead of *#a0 Add a2, a3 a1 = #a0* saving a temporary variable and an opcode call. Less opcode calls result in reduced CPU usage (an average orchestra may compile about 10% faster with *--expression-opt*, but it depends largely on how many expressions are used, what the control rate is (see also below), etc.; thus, the difference may be less, but also much more).
- number of a- and k-rate temporary variables is significantly reduced. This expression

*(a1 + a2 + a3 + a4)*

will compile as

```
#a0 Add a1, a2
#a0 Add #a0, a3
#a0 Add #a0, a4      ; (the result is in #a0)
```

instead of

```
#a0 Add a1, a2
#a1 Add #a0, a3
#a2 Add #a1, a4      ; (the result is in #a2)
```

The advantages of less temporary variables are:

- less cache memory is used, which may improve performance of orchestras with many a-rate expressions and a low control rate (e.g. ksmmps = 100)
- large orchestras may load faster due to less different identifier names
- index overflow errors (i.e. when messages like this Case2: indx=-56004 (ffff253c); (short)indx = 9532 (253c) are printed and odd behavior or a Csound crash occurs) may be fixed, because such errors are triggered by too many different (especially a-rate) variable names in a single instrument.

Note that this optimization (due to technical reasons) is not performed on i-rate temporary variables.

## Warning

When --expression-opt is turned on, it is not allowed to use the i() function with an expression argument, and relying on the value of k-rate expressions at i-time is unsafe.

|                         |   |
|-------------------------|---|
| --get-system-sr         | PObtain the machine's sample rate.  |
| --help                  | Display on-line help message.   |
| --devices               | Gives a list of available audio devices and then exits.   |
| -I, --i-only            | <i>i-time only.</i> Allocate and initialize all instruments as per the score, but skip all p-time processing (no k-signals or a-signals, and thus no amplitudes and no sound). Provides a fast validity check of the score pfields and orchestra i-variables. This option is exclusive of the --syntax-check-only flag. |
| -+ignore_csopts=integer | If set to 1, Csound will ignore all options specified in the csd file's CsOptions section. See <i>Unified File Format for Orchestras and Scores</i> .   |
| --ksmps=N               | Set ksmmps override to N (6.05 and later).  |
| -+max_str_len=integer   | (min: 10, max: 10000) Maximum length of string variables + 1; defaults to 256 allowing a length of 255 characters. The length of string constants is not limited by this parameter.   |
| -N, --notify            | Notify (ring the bell) when score or MIDI track is done.  |

|   |   |
|---|---|
| --no-default-paths  | Disables adding of directory of CSD/ORC/SCO to search paths.  |
| --no-expression-opt   | Disables expression optimization.   |
| -O FILE, --logfile=FILE   | Log output to file <i>FILE</i> . If <i>FILE</i> is null (i.e. <i>-O null</i> or <i>-logfile=null</i> ) all printing of messages to the console is disabled.   |
|  | <b>Note</b><br>This option only works from the command line and not from .csound6rc or a CsOptions section of a csd file. It needs to be acted upon before sound proper starts. It is ignored in .csoundrc and CsOptions.                 |
| --opcode-lib=LIBNAME  | Load plugin library <i>LIBNAME</i> .  |
| --orc orcname   | Set the argument as the orchestra file. Used when not score is required>. (Csound 5.18 and later).  |
| --syntax-check-only   | Causes Csound to exit immediately after the orchestra and score parsers finish checking the syntax of the input files and before the orchestra performs the score. This option is exclusive of the -i-only flag. (Csound 5.08 and later). |
| -t0, --keep-sorted-score  | Prevents Csound from deleting the sorted score file, score.srt, upon exit.  |
| -U UTILITY, --utility=UTILITY   | Invoke the utility program <i>UTILITY</i> . Use any invalid name to list the available utilities.   |
| -x FILE, --extract-score=FILE   | Extract a portion of the sorted score, score.srt, using the extract file <i>FILE</i> (see <i>Extract</i> ).   |

## Csound Environment Variables

The following environment variables can be used by Csound:

- SFDIR: Default directory for sound files. Used if no full path is given for sound files.
- SSDIR: Default directory for input (source) audio and MIDI files. Used if no full path is given for sound files. May be used in conjunction with SFDIR to set separate input and output directories. Please note that MIDI files as well as audio files are also sought inside SSDIR.
- SADIR: Default directory for analysis files. Used if no full path is given for analysis files.
- SFOUTYP: Sets the default output file type. Currently only 'WAV', 'AIFF' and 'IRCAM' are valid. This flag is checked by the csound executable and the utilities and is used if no file output type is specified.
- INCDIR: Include directory. Specifies the location of files used by *#include* statements.
- OP CODE6DIR: Defines the location of csound opcode plugins for the single precision float (32-bit) version.
- OP CODE6DIR64: Defines the location of csound opcode plugins for the double precision float (64-bit) version.

- **SNAPDIR**: Is used by the FLTK widget opcodes when loading and saving snapshots.
- **CSOUNDRC**: Defines the csound resource (or configuration) file. A full path and filename containing csound flags must be specified. This variable defaults to `.csoundrc` if not present.
- **CSSTRNGS**: In Csound 5.00 and later versions, the localisation of messages is controlled by two environment variables `CSSTRNGS` and `CS_LANG`, both of which are optional. `CSSTRNGS` points to a directory containing `.xmg` files.
- **CS\_LANG**: Selects a language for csound messages.
- **RAWWAVE\_PATH**: Is used by the STK opcodes to find the raw wave files. Only relevant if you are using STK wrapper opcodes like `STKBowed` or `STKBrass`.
- **CSONSTOP**: If this environment variable is set to "yes", then any graph displays are closed automatically at the end of performance (meaning that you possibly will not see much of them in the case of a short non-realtime render). Otherwise, you need to click "Quit" in the FLTK display window to exit, allowing for viewing the graphs even after the end of score is reached.
- **MFDIR**: Default directory for MIDI files. Used if no full path is given for MIDI files. Please note that MIDI files are sought in `SSDIR` and `SFDIR` as well.
- **CS OMIT LIBS**: Allows defining a list of plugin libraries that should be skipped. Libraries can be separated with commas, and don't require the "lib" prefix.

For more information about `SFDIR`, `SSDIR`, `SADIR`, `MFDIR` and `INCDIR` see *Directories and files*.

The only mandatory environment variables are `OPCODE6DIR` and `OPCODE6DIR64`. It is very important to set them correctly, otherwise most of the opcodes will not be available. Make sure you set the path correctly depending on the precision of your binary. if you run `csound` on a command line without any arguments you should see some text like : Csound version 6.03.1 (double samples) May 10 2014. This text refers to the double precision version.

`CSSTRNGS` and `CS_LANG` currently have very limited use since Csound has not yet been completely translated into other languages.

Other environment variables which are not exclusive to Csound but which might be of importance are:

- **PATH**: The directory containing csound executables should be listed in this variable.
- **PYTHONPATH**: If you intend to use CsoundVST and python, the directory containing the `_CsoundVST` shared library and the `CsoundVST.py` file must be in your `PYTHONPATH` environment variable (or the default path python searches in), so that the Python runtime knows how to load these files.
- **LADSPA\_PATH and DSSI\_PATH**: These environment variables are required if you are using the `dssi4cs` (LADSPA and DSSI host) plug-in opcodes.
- **CSDOCDIR**: Specifies the directory where the html help files are located. Though not used by Csound directly, this environment variable can help front-ends and editors (which implement it) to find the csound manual.

## Setting environment variables

### On the command line

---

You can set environment variables on the command line or the configuration file .csoundrc by using the command line flag --env:NAME=VALUE or --env:NAME+=VALUE, where NAME is the environment variable name, and VALUE is its value. See *Command-line Flags*

### Note

Please note that this method of setting environment variables will not work for variables which are parsed before the command line arguments. SADIR, SSDIR, SFDIR, INCDIR, SNAPDIR, RAWWAVE\_PATH, CSNOSTOP, SFOUTYP should work, but the following environment variables must be set on the system prior to running csound: OPCODE6DIR, OPCODE6DIR64, CSSTRINGS, and CS\_LANG. CSOUNDRC can currently (v. 5.02) be set using --env, but this behavior is not guaranteed for future versions.

## Windows

To set a csound environment on Windows XP and 2000 go to Control Panel->System->Advanced and click on the button 'Environment Variables'. On other versions of Windows earlier than Windows XP and Windows 2000 you set environment variables in the autoexec.bat file. Go to 'My Computer', select C: drive, right click on autoexec.bat, and select 'Edit'. The statement format is: SET NAME=VALUE .

## Linux

You can set environment variables on Linux in many ways. You can set them using the *export* shell command, by setting them on .bashrc or similar files or by adding them to the /etc/profile file.

## Mac

```
~$ export OPCODE6DIR64=/Users/you/your/Csound6/build
```

in addition if the bash shell is the default, then it is usually easier to edit your .bashrc or /etc/profile.

Note that if users choose one of the above methods, ie editing the .bashrc file then the environment variables are executed when a new shell is created. This can be problematic if your application implements a Quartz or Aqua interface and does not use the commandline.

If this is the case, then the standard solution (up to OS 10.3.9 and unless the application uses the csound-API and sets the environ variables directly) is to create an XML property list file (called a .plist file by the OS). This file should nominally be located at ~/.MacOSX/Environment.plist. This has been a solution specifically for the [csoundapi~] object for Pd on OS X. Since Pd uses an OS X native .app style packaging, and runs off of the Aqua interface, the standard means of supplying environment variables to Csound do not work. The solution is to set Csound's environment variables for the Aqua environment.

Likely, most users will not have the hidden folder .MacOSX located in their \$HOME directory (aka ~/). This folder must first be created and the Environment.plist added to this folder. The contents of the Environment.plist file should be something like:

```
<?xml version="1.0" encoding='UTF-8'?>
<!DOCTYPE plist PUBLIC "-//Apple Computer//DTD PLIST 1.0//EN"
  "http://www.apple.com/DTDs/PropertyList-1.0.dtd">
<plist version="1.0">
<dict>
<key>OPCODEDIR</key>
<string>/Library/Frameworks/CsoundLib.framework/Versions/5.1/Resources/Opcodes</string>
<key>OPCODEDIR64</key>
<string>/Volumes/ExternalHD-devel/csound5/lib64</string>
<key>INCDIR</key>
<string>/Volumes/ExternalHD/CSOUND/include</string>
<key>SFDIR</key>
<string>/Volumes/ExternalHD/iTunes/csoundaudio</string>
```

```
</dict>
</plist>
```

and so on, using the XML `<key>` tag for each environment variable required by the API and the `<string>` tag for its corresponding path on the system.

Please note that you must login out and login in for these changes to take effect.

# Unified File Format for Orchestras and Scores

## Description

The Unified File Format, introduced in Csound version 3.50, enables the orchestra and score files, as well as command line flags, to be combined in one file. The file has the extension `.csd`. This format was originally introduced by Michael Gogins in AXCsound.

The file is a structured data file which uses markup language, similar to any SGML such as HTML. Start tags (`<tag>`) and end tags (`</tag>`) are used to delimit the various elements. The file is saved as a text file.

## Structured Data File Format

### Mandatory Elements

The first tag in the file must be the start tag `<CsoundSynthesizer>`. The last tag in the file must be the end tag `</CsoundSynthesizer>`. This element is used to alert the csound compiler to the `.csd` format. All text before the start tag and after the end tag is ignored by Csound. The tag may also be spelled `<CsoundSynthesiser>`.

### Options (`<CsOptions>`)

Csound *command line flags* are put in the Options Element. This section is delimited by the start tag `<CsOptions>` and the end tag `</CsOptions>`. Lines beginning with # or ; are treated as comments.

### Orchestra (`<CsInstruments>`)

The instrument definitions (orchestra) are put into the Instruments Element. The statements and syntax in this section are identical to the Csound *orchestra file*, and have the same requirements, including the header statements (`sr`, `kr`, etc.) This Instruments Element is delimited with the start tag `<CsInstruments>` and the end tag `</CsInstruments>`.

### Score (`<CsScore>`)

Csound score statements are put in the Score Element. The statements and syntax in this section are identical to the Csound *score file*, and have the same requirements. The Score Element is delimited by the start tag `<CsScore>` and the end tag `</CsScore>`.

As an alternative Csound score statements can also be generated by an external program using the CsScore scheme with an attribute bin. The lines upto the closing tag `</CsScore>` are copied to a file and the external program named is called with that file name and the destination score file. The external program should create a standard Csound score.

### Optional Elements

## Included Base64 Files (<CsFileB>)

Base64-encoded files may be included with the tag <*CsFileB* filename=*filename*>, where *filename* is the name of the file to be included. The Base64-encoded data should be terminated with a </*CsFileB*> tag. For encoding files, the csb64enc and makecsd utilities (included with Csound 5.00 and newer) can be used. The file will be extracted to the current directory, and deleted at end of performance. If there is an already existing file with the same name, it is not overwritten, but an error will occur instead.

Base64-encoded MIDI files may be included with the tag <*CsMidifileB* filename=*filename*>, where *filename* is the name of the file containing the MIDI information. There is no matching end tag. This was added in Csound version 4.07. Note: using this tag is not recommended; use <*CsFileB*> instead.

Base64-encoded sample files may be included with the tag <*CsSampleB* filename=*filename*>, where *filename* is the name of the file containing the sample. There is no matching end tag. This was added in Csound version 4.07. Note: using this tag is not recommended; use <*CsFileB*> instead.

## Included Unencoded Files (<CsFile>)

Unencoded files may be included with the tag <*CsFile* filename=*filename*>, where *filename* is the name of the file to be included. The data should be terminated with a </*CsFile*> tag alone on a line. The file will be extracted to the current directory, and deleted at end of performance. If there is an already existing file with the same name, it is not overwritten, but an error will occur instead.

## Version Blocking (<CsVersion>)

Versions of Csound may be blocked by placing one of the following statements between the start tag <*CsVersion*> and the end tag </*CsVersion*>:

Before #.#

or

After #.#

where #.# is the requested Csound version number. The second statement may be written simply as:

#.#

This was added in Csound version 4.09.

## Licence Information (<CsLicence> or <CsLicense>)

Licencing details can be included in between the start tag <*CsLicence*> and the end tag </*CsLicence*>. There is no format for this information, any text is acceptable. This text will be printed by Csound to the console when the CSD is run.

## Licence Information (<CsShortLicence> or <CsShortLicense>)

From version 6.05 licencing details can be also included in between the start tag <*CsShortLicence*> and the end tag </*CsShortLicence*>. This offers seven well-known licences, coded as an integer.

0: "All rights reserved" (default)

- 1: "Creative Commons Attribution-NonCommercial-NoDerivatives (CC BY-NC-ND)"
- 2: "Creative Commons Attribution-NonCommercial-ShareAlike (CC BY-NC-SA)"
- 3: "Creative Commons Attribution-NonCommercial (CC BY-NC)"
- 4: "Creative Commons Attribution-NoDerivatives (CC BY-ND)"
- 5: "Creative Commons Attribution-ShareAlike (CC BY-SA)"
- 6: "Creative Commons Attribution-ShareAlike (CC BY)"
- 7: "Licenced under BSD"

## Embedded HTML (<html>)

Any valid HTML code can be embedded in the CSD file. This code should be structured exactly like an ordinary Web page. This code can contain any valid HTML, JavaScript, Cascading Style Sheet, WebGL, etc., etc. code.

In some Csound front ends and programming environments, including at least CsoundQt or Csound for Android, this page will be parsed, executed, and displayed by a Web browser embedded in the environment. JavaScript code in this page will have access to a global *csound* object that implements the following functions, which are a selected subset of the Csound API. The names, data types, and uses of these functions are exactly the same as detailed in the Csound API Reference Manual.

```
[int] getVersion ();
compileOrc (orchestra_text);
[double] evalCode (orchestra_expression);
readScore (score_text);
setControlChannel (channel_name, numeric_value);
[double] getControlChannel (channel_name);
message (message_string);
[int] getSr ();
[int] getKsmmps ();
[int] getNchnls ();
// Not a part of the Csound API -- called by the environment to detect whether Csound is running.
[int] isPlaying ();
```

The HTML element of the CSD file can be used to create custom user interfaces for the piece, to generate score events and even orchestra code using JavaScript, to store presets for widgets, and for many other purposes. The *GameOfLife3D.csd* [examples/GameOfLife3D.csd] and *LindenmayerCanvas.csd* [examples/LindenmayerCanvas.csd] examples demonstrate these uses (tested in CsoundQt; running these examples requires additional resources found in the Csound examples directory in GIT).

## Example

Below is a sample file, test.csd, which renders a .wav file at 44.1 kHz sample rate containing one second of a 1 kHz sine wave. Displays are suppressed. test.csd was created from two files, tone.orc and tone.sco, with the addition of command line flags.

```
<CsoundSynthesizer>
; test.csd - a Csound structured data file

<CsOptions>
-W -d -o tone.wav
</CsOptions>

<CsVersion>      ; optional section
Before 4.10       ; these two statements check for
After 4.08        ; Csound version 4.09
</CsVersion>

<CsInstruments>
; originally tone.orc
sr = 44100
kr = 4410
ksmps = 10
```

```
nchnls = 1
instr 1
    a1 oscil p4, p5, 1 ; simple oscillator
    out a1
endin
/>CsInstruments>

<CsScore>
; originally tone.sco
f1 0 8192 10 1
i1 0 1 20000 1000 ; play one second of one kHz tone
e
/>CsScore>

/>CsoundSynthesizer>
```

## Command Line Parameter File (.csoundrc)

If the file *.csoundrc* exists, it will be used to set the command line parameters. These can be overridden. Csound 5.00 and newer versions read this file from the HOME directory first (or the full path file name defined by the CSOUNDRC *environment variable*), and then the current directory. If both exist, options in the *.csoundrc* in the current directory will have higher precedence. It uses the same form as a *.csd* file, but no tags are needed. Lines beginning with # or ; are treated as comments.

A *.csoundrc* file can contain something like this:

```
-+rtaudio=portaudio -odac2 -iadc2 -+rtmidi=winmme -M1 -Q1 -m0
```

In this case, csound will generate real-time output and take realtime input from device 2, using the portaudio driver interface. It will input and output realtime MIDI on interface 1. It will print very few messages (-m0). These options will be used by default when other options are not given inside the <CsOptions> of the *.csd* file or the command line (See *Order of precedence*).

## Score File Preprocessing

### The Extract Feature

This feature will extract a segment of a sorted numeric score file according to instructions taken from a control file. The control file contains an instrument list and two time points, from and to, in the form:

```
instruments 1 2 from 1:27.5 to 2:2
```

The component labels may be abbreviated as i, f and t. The time points denote the beginning and end of the extract in terms of:

```
[section no.] : [beat no.].
```

Each of the three parts of the argument is optional. The default values for missing i, f or t are:

```
all instruments, beginning of score, end of score.
```

## Independent Pre-Processing with Scsort

Although the result of all score preprocessing is retained in the file score.srt after orchestra performance (it exists as soon as score preprocessing has completed), the user may sometimes want to run these phases independently. The command

```
scot filename
```

will process the Scot formatted filename, and leave a *standard numeric score* result in a file named score for perusal or later processing.

The command

```
scsort < infile > outfile
```

will put a numeric score infile through Carry, Tempo, and Sort preprocessing, leaving the result in outfile.

Likewise *extract*, also normally invoked as part of the *Csound command*, can be invoked as a standalone program:

```
extract xfile < score.sort > score.extract
```

This command expects an already sorted score. An unsorted score should first be sent through Scsort then piped to the extract program:

```
scsort < scorefile | extract xfile > score.extract
```

---

# Using Csound

Csound can be operated in a variety of modes and configurations. The original method for running Csound was as a console program (DOS prompt for Windows, Terminal for Mac OS X). This, of course, still works. Running `csound` without any arguments prints out a list of command-line options, which are more fully explained in the *Command Line Flags (by Category)* section. Normally, the user executes something like:

```
csound myfile.csd
```

or separate orchestra (orc) and score (sco) files can be used:

```
csound myorchestra.orc myscore.sco
```

You can find many .csd files in the examples folder. Most opcode entries in this manual also include simple .csd files showing the usage of the opcode.

There are also many *Front-Ends* which can be used to run `csound`. A *Front-End* is a graphical program that eases the process of running `csound`, and sometimes provides editing and composing functions.

Csound also has several ways of producing output. It can:

- Read and write soundfiles (off-line rendering) - Using the `-o` and `-i` flags specifying an output filename.
- Read and write digital audio using a sound card (real-time rendering) - Using the `-odac` and `-iadc` flags
- Read and write MIDI files (non-realtime) - Using the `-F` and `--midioutfile` flags.
- Read and write MIDI using a MIDI interface and controller (real-time control) - Using the `-M` and `-Q` flags.

## Csound's Console Output

When Csound runs, it prints a text output to the console, which shows data about the Csound run. A Console output looks something like this:

```
time resolution is 0.455 ns
PortMIDI real time MIDI plugin for Csound
virtual_keyboard real time MIDI plugin for Csound
PortAudio real-time audio module for Csound
0dBFS level = 32768.0
Csound version 5.10 beta (float samples) Apr 19 2009
libsndfile-1.0.17
Reading options from $HOME/.csoundrc
UnifiedCSD: oscil.csd

Creating options
Creating orchestra
Creating score
orchname: /tmp/csound-XYACV6.orc
scorename: /tmp/csound-IYtLAJ.sco
rtaudio: ALSA module enabled
rtmidi: PortMIDI module enabled
orch compiler:
17 lines read
      instr 1
Elapsed time at end of orchestra compile: real: 0.129s, CPU: 0.020s
sorting score ...
      ... done
```

```
Elapsed time at end of score sort: real: 0.130s, CPU: 0.020s
Csound version 5.10 beta (float samples) Apr 19 2009
displays suppressed
0dBFS level = 32768.0
orch now loaded
audio buffered in 256 sample-frame blocks
ALSA input: total buffer size: 1024, period size: 256
reading 1024-byte blks of shorts from adc (RAW)
ALSA output: total buffer size: 1024, period size: 256
writing 1024-byte blks of shorts to dac
SECTION 1:
ftable 1:
new alloc for instr 1:
B 0.000 .. 2.000 T 2.000 TT 2.000 M: 10000.0 10000.0
Score finished in csoundPerform().
inactive allocs returned to freespace
end of score.          overall amps: 10000.0 10000.0
                        overall samples out of range:      0      0
0 errors in performance
Elapsed time at end of performance: real: 2.341s, CPU: 0.050s
345 1024-byte soundblks of shorts written to dac
Removing temporary file /tmp/csound-CoVcrm.srt ...
Removing temporary file /tmp/csound-IYtLAJ.sco ...
Removing temporary file /tmp/csound-XYACV6.orc ...
```

The console output of Csound is quite verbose, particularly before the actual performance (like version, plugins loaded, etc.). Performance actually started when the console printed:

SECTION 1:

In this particular run, the lines:

```
new alloc for instr 1:
B 0.000 .. 2.000 T 2.000 TT 2.000 M: 10000.0 10000.0
```

Show that a single note for instrument 1, that lasted 2 seconds starting at time 0.000, was produced with an amplitude of 10000 for both channel 1 and 2. An important section of the console output is:

```
end of score.          overall amps: 10000.0 10000.0
                        overall samples out of range:      0      0
```

Which shows the overall amplitude and the number of samples which were clipped because they were out of range.

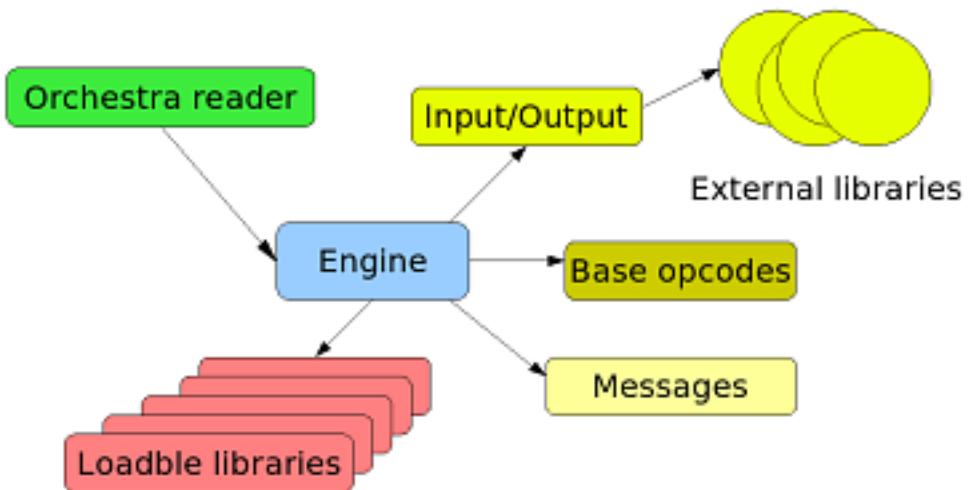

The line:

```
Elapsed time at end of performance: real: 2.341s, CPU: 0.050s
```

Shows the clock time and the CPU time it takes for the processor to complete the task. If CPU time is lower than clock time it means the csd can run in realtime (unless it has some sections which are extremely CPU intensive). The "real time" figure is the total running time and it is larger because it accounts for disk access, module loading, etc. (CPU time is strictly number-crunching time). If you have a sound that lasts for 100s and it takes 5s to generate it offline, it means that you are taking around 5% of CPU, and that it runs on 0.05 of realtime.

## How Csound works

Csound processes and generates output using "unit generators" (ugens) called *opcodes*. These opcodes are used to define *instruments* in the *orchestra*. When you run Csound, the engine loads the base Op-codes, and the opcodes contained in separate loadable "opcode libraries". It then interprets the orchestra (through the orchestra reader). The engine sets up an instrument processing chain, which then receives events from the score or in real-time. The processing chain uses the input/output modules to generate output. There are modules that can write to file, or generate *real-time audio output*.

The Csound Modular structure.

## Csound's processing buffers

Csound processes audio in sample blocks called buffers. There are three separate buffer layers:

1. *spout* = Csound's innermost software buffer, contains *ksmps* sample frames. Csound processes real-time control events once every *ksmps* sample frames.
2. *-b* = Csound's intermediate software buffer (the "software" buffer), in sample frames. Should be (but does not need to be) an integral multiple of *ksmps* (can equal *ksmps* too). Once per *ksmps* sample frames, Csound copies *spout* to the *-b* buffer. Once per *-b* sample frames, Csound copies the *-b* buffer to the *-B* "hardware" buffer.
3. *-B* = The sound card's internal buffer (the "hardware" buffer), in sample frames. Should be (and may need to be) an integral multiple of *-b*. If Csound misses delivering a *-b* one time, the extra *-b* sample frames in *-b* are still there for the sound card to keep playing while Csound catches up. But they can be the same size if you're willing to bet Csound can always keep up with the sound card.

## Amplitude values in Csound

Amplitude values in Csound are always relative to a "*0dbfs*" value representing the peak available amplitude before clipping, in either an AD/DA codec, or in a soundfile with a defined range (which both WAVE and AIFF are). In the original Csound, this value was always 32767, corresponding to the bipolar range of a 16bit soundfile or 16bit AD/DA codec, Csound's only possible output back then. This remains the *default* peak amplitude for Csound, for backward compatibility and you will find some of this manual's examples still use this value (hence you find large amplitude values like 10000).

The *0dbfs* value enables Csound to produce appropriately scaled values to whatever output format is being used, whether 24bit integer, 32bit floats, or even 32bit integers. Put another way, the literal amp-

litude values you write in a Csound instrument only match those written *literally* to the file if the *0dbfs* value in Csound corresponds exactly to that of the output sample format. The consequence of this approach is that you can write a piece with a certain amplitude and have it render correctly and identically (setting aside of course the better dynamic range of the high-res formats) whether written to an integer or floats file, or rendered in real-time.

## Note

The one exception to this is if you choose to write to a "raw" (headerless) file format. In such cases the internal *0dbfs* value is meaningless, and whatever values you use are written unmodified. This does enable arbitrary data to be generated or processed by Csound. It is a relatively exotic thing to do, but some users need it.

You can choose to redefine the *0dbfs* value in the orchestra header, purely for your own convenience or preference. Many people will choose 1.0 (the standard for SAOL, other software like Pure Data, and for many plugin standards such as VST, LADSPA, CoreAudio AudioUnits, etc), but any value is possible.

The common factor in defining amplitudes is the decibel (dB) scale, with  $0\text{dB}_{\text{FS}}$  always understood as digital peak; hence "0dbfs" means "0dB Full-Scale value". This measure is different to actual amplitude values, since amplitude values are a linear scale which show the actual oscillation around 0, so they can be positive or negative. Decibel values are an absolute logarithmic scale, but can be useful for most op-codes as well. You can convert amplitude to and from decibels using the *ampdb*, *ampdbfs*, *dbamp* and *dbfsamp* functions. This way, Csound enables the programmer to express all amplitudes in dB - lower amplitudes will then be represented by negative dB values. This reflects industry practice (e.g. in level meters in mixers, etc).

For example the same dB level of -6dB (half the amplitude) or -20dB are actually a different linear amplitude according to 0dbfs like this:

**Table 2. dB<sub>FS</sub> in relation to amplitude**

| <b>dB<sub>FS</sub></b> | <b>0dbfs = 32767 (default)</b> | <b>0dbfs = 1</b> | <b>0dbfs = 1000 (unusual)</b> |
|------------------------|--------------------------------|------------------|-------------------------------|
| 0 dB                   | 32767                          | 1                | 1000                          |
| -6 dB                  | 16384                          | 0.5              | 500                           |
| -20 dB                 | 3276.7                         | 0.1              | 100                           |

Some Csound users might therefore be minded to express all levels in  $\text{dB}_{\text{FS}}$ , and obviate any confusion or ambiguity of level that may otherwise arise when using explicit amplitude values. The decibel scale reflects the response of the ear pretty closely, and that when you want to express a really quiet level, it might be easier and more expressive to write "-46dB" than "0.005" or "163.8".

The reason for using 0dbfs is very simple: digital peak equates to maximum level regardless of sample resolution. If you then define a signal at -110dB you will lose it if rendering to a 16bit file, but retain it (audibly or not) if rendering to 24bit or better. In other words, there is a fixed ceiling, but a moveable floor - you can define sounds as quietly as you like (e.g. envelope tails), in a predictable way, and preserve them or not (without changing the orch code at all), depending on the resolution (file or audio i/o) you render to.

## A note on digital amplitude, decibels and dynamic range

A convenient approximation of dynamic range for a certain digital precision is to calculate the decibel interval between the minimum value and the maximum value for a sample. As a rule of thumb, 1 bit (doubling of level) is 6dB, so 16bits = 96dB.

This is not entirely accurate since audio sample values are represented on a bipolar scale with positive and negative values, and 1 bit is used for the sign. Therefore, for 16bit integer samples actually use 1 bit for the sign and 15 bits for the values, so the actual dynamic range is 90dB.

## Real-Time Audio

The following information applies mostly to csound being run directly from the command line. Frontends implement these features in different ways, but knowledge of them is necessary in some of them.

The `-i` and `-o` flags can be used to specify realtime output instead of the ordinary non-realtime file output. You should use `-o dac` for realtime output and `-i adc` for realtime input. Naturally, you can use either one or both if your hardware supports it. You can also specify the hardware you want to use by appending a device number or name to the flag (See `-i` and `-o`).

You might also need to use the `+rtaudio` flag to specify the driver interface to be used. Csound defaults to using Portaudio, which is cross-platform and reliable, but for better performance, you might need to use ALSA or JACK on linux, and CoreAudio on Mac. You can use ASIO on Windows if your version of Portaudio has been compiled with ASIO support.

You can see a list of available devices by giving a device number which is out of range, for instance `-o dac99`. This will also reveal if you have ASIO available if you are using PortAudio.

## Period & Buffer Sizes

Period and buffer sizes will vary greatly from one machine to another. Lower buffer sizes will result in lower latency, but might cause breakups or clicks in the audio. The Csound flags which control period and buffer sizes are `-b` and `-B`, respectively. Buffer size is hardware dependant, and some experimentation may be necessary to find the optimal balance between low latency performance and uninterrupted audio output. The values given to `-b` and `-B` should be powers of two, and the value of `-B` should be at least one power of two higher than that of `-b`.

Currently, with `-B` set to 512, audio output latency is about 12 milliseconds, fast enough for reasonably responsive keyboard playing. Even shorter latencies, are feasible on some systems.

## Control Rate

Low values for `ksmps` will in general give a higher quality of synthesis, but will consume more system resources. There is no hard and fast rule for setting `ksmps` - different orchestras will require different control rates. A waveguide instrument will need a `ksmps` of 1 (and may not be suitable for realtime use), whereas a simple FM synth may be run with a higher `ksmps` without noticeable degradation of sound. If the FM synth were to be used to play a monophonic bassline, a very low `ksmps` may be used, however more complex note clusters will require a higher `ksmps`. A well-tuned Linux system should be capable of running even complex polyphonic synths with `ksmps` values as low as 4 or 8. If full duplex audio is required, `-b` must be an integer multiple of `ksmps`. Bearing this in mind, a rule of thumb might be to only use powers of two for `ksmps`.

Some settings differ according to platform. See further below for information for each platform.

## Realtime I/O on Linux

Under Linux, the default PortAudio/PortMidi settings will result in higher latency than that which can be achieved using ALSA and/or JACK. The PortMusic plugins are audio and MIDI servers, which provide

an interface to the ALSA drivers, in a manner which is in some respects similar but fundamentally different from that provided by JACK. For a more detailed comparison please refer to:

<http://jackaudio.org/faq>

## Using ALSA

The highest level of control and the lowest possible level of latency are to be achieved using the ALSA plugins in combination with the *--sched* flag. Using *--sched* requires that Csound be run as the root user, which may be impossible or undesirable in some circumstances.

The ALSA plugins require the "name" of a "card" and a "device". Unless you have named your "cards" in *~/.asoundrc* (or */etc/asound.conf*), the "names" will actually be numbers. In order to obtain a list of the possible configurations, use the command line utilities "aplay", "arecord" and "amidi". These utilities are included with most Linux distros, or can be downloaded and built from source here:

<ftp://ftp.alsa-project.org/pub/utils/>

### Note

On every boot, the soundcard may have a different hardware order number, especially when there are more soundcards in the system. This can be awkward as every time you have to set the right number again. You can assign a fixed order by adding some lines to */etc/modprobe.d/alsa-base-conf*, for example for a card with the ice1712 chip :

```
# ALSA module ordering for soundcard
options snd slots=snd_ice1712
```

## Audio Output

Running the following command:

```
aplay -l
```

will give you a list of the audio playback devices available on your system. Typically this list will look something like:

```
[....]
**** List of PLAYBACK Hardware Devices ****
card 0: A5451 [ALI 5451], device 0: ALI 5451 [ALI 5451]
[....]
```

If you have more than one card on your system, or if there is more than one device on your card, the list will of course be more complicated, however in all cases the information that is pertinent is the number/name of the card/device. In order to use the above soundcard for audio output, the following flag would be added to the Csound command line, *~/.csoundrc*, or the <CsOptions> section of a CSD:

```
-+rtaudio=alsa -o dac
```

## Output with dmix

If you would like to use Csound with dmix and your soundcard does not support hardware mixing of audio streams, special care is needed in setting up of software (-b) and hardware (-B) buffers. If you get a message from Csound's ALSA driver that looks like the following:

```
ALSA: -B 8192 not allowed on this device; use 7526 instead
```

there is a good chance that you may be using dmix. If you are using dmix, the -b and -B settings of Csound must be synced the period\_size and buffer\_size of dmix respectively, using a ratio of the sr for the Csound project to the sample rate that dmix is set up to. The following formula will determine what settings to use for Csound given the settings of dmix:

```
-b = (csound_sr/dmix_sample_rate) * dmix_period_size  
-B = (csound_sr/dmix_sample_rate) * dmix_buffer_size
```

For example, if dmix is set to 48000 sample rate, a period\_size of 1024, and a buffer\_size of 8192, when running a Csound project with sr=48000, the settings for buffers should be "-b 1024 -B8192". If the sr=24000, the settings for buffers should be "-b 512 -B4096".

Because of this relationship, if a Csound project's sr does not evenly divide into the sample\_rate used by dmix, then it may be difficult if not impossible to set the correct setting for -b and -B due to rounding errors. It is suggested then that if you are using sample rates different than what your setting is for dmix, then you may want to configure dmix to have a period\_size and buffer\_size that can be evenly divided by the ratio between the csound sr and dmix sample\_rate. For example, to run a project with sr=16000, the following dmix setting:

```
pcm.amix {  
    type dmix  
    ipc_key 50557  
    slave {  
        pcm "hw:0,0"  
        period_time 0  
        #period_size 1024  
        #buffer_size 8192  
        period_size 1536  
        buffer_size 12288  
    }  
    bindings {  
        0 0  
        1 1  
    }  
}  
  
# route ALSA software through pcm.amix  
pcm.!default {  
    type plug  
    slave.pcm "amix"  
}
```

with period\_size 1536 and buffer\_size 12288 will divide nicely by 3 (the ratio of the csound sr to the dmix sample\_rate) to get "-b 512 -B4096" ( $(16000/48000) * 1536 = 512$ ,  $(16000/48000) * 12288 = 4096$  ).

### Note

For most soundcards that this affects, the default sample rate for the card will be 48000 and the defaults for dmix will be 1024 and 8192.

## Audio Input

Typically the same card will be used for both input and output, so to continue using the foregoing ex-

ample, the flag:

```
-i adc:hw:0,0
```

would be added for audio input from Card 0 Device 0. To use the default card employ one of the following flags, with the forementioned warning that this will not necessarily work:

```
-i adc
```

If you wish to use a different card or device for input, running the following utility from the command line will provide a list of input devices:

```
arecord -l
```

If, by way of an example, you wanted to use a USB audio interface, which is the second "card" in your system, for output, but wanted to use your internal soundcard, the first card in your setup, for input, you would put the following flags somewhere useful:

```
-+rtaudio=alsa -i adc:hw:0,0 -o dac:hw:1,0
```

If you wanted to use the second device on your USB interface, to send audio to a specific channel, for instance, you would use the following flags:

```
-+rtaudio=alsa -i adc:hw:0,0 -o dac:hw:1,1
```

## MIDI

2 Midi drivers are available:

- Raw Midi.
- Alsa Sequencer (since version 5.18).

## MIDI Input (Raw Midi driver)

In order to enable your orchestra to receive MIDI input you can use VirMIDI or MIDIThru, whichever you prefer. Setting up these virtual MIDI ports is a topic that has been covered extensively elsewhere, see The Linux MIDI how-to [<http://www.midi-howto.com/>] or browse your distro's documentation or the ALSA documentation for instructions on how to install and configure either VirMIDI or MIDIThru (seqdummy). Once you have done so run:

```
amidi -l
```

for a list of available devices. Typically this will look something like the following:

```
[....]
Device  Name
hw:1,0  Virtual Raw MIDI (16 subdevices)
```

```
hw:1,1  Virtual Raw MIDI (16 subdevices)
hw:1,2  Virtual Raw MIDI (16 subdevices)
hw:1,3  Virtual Raw MIDI (16 subdevices)
hw:2,0,0  PCR MIDI
hw:2,0,1  PCR 1
```

In this example, Csound can connect to any of the four available Virtual Raw MIDI ports, where it will listen for MIDI input. The following flag instructs Csound to listen on the first of these ports:

```
-+rtmidi=alsa -Mhw:1,0
```

You will then need to connect your hardware or software controller to the port which is hosting your Csound synthesizer. The simplest way to do this is using the "aconnect" utility. Run:

```
aconnect -li
```

for a list of available input devices, and:

```
aconnect -lo
```

for a list of available output devices (including the port to which Csound has been connected). These should give something like the following:

```
#aconnect -li
client 0: 'System' [type=kernel]
  0 'Timer'
  1 'Announce'
    Connecting To: 15:0
client 20: 'Virtual Raw MIDI 1-0' [type=kernel]
  0 'VirMIDI 1-0'
client 21: 'Virtual Raw MIDI 1-1' [type=kernel]
  0 'VirMIDI 1-1'
client 22: 'Virtual Raw MIDI 1-2' [type=kernel]
  0 'VirMIDI 1-2'
client 23: 'Virtual Raw MIDI 1-3' [type=kernel]
  0 'VirMIDI 1-3'
client 24: 'PCR' [type=kernel]
  0 'PCR MIDI'
  1 'PCR 1'
  2 'PCR 2'
```

```
#aconnect -lo
client 20: 'Virtual Raw MIDI 1-0' [type=kernel]
  0 'VirMIDI 1-0'
client 21: 'Virtual Raw MIDI 1-1' [type=kernel]
  0 'VirMIDI 1-1'
client 22: 'Virtual Raw MIDI 1-2' [type=kernel]
  0 'VirMIDI 1-2'
client 23: 'Virtual Raw MIDI 1-3' [type=kernel]
  0 'VirMIDI 1-3'
client 24: 'PCR' [type=kernel]
```

```
0 'PCR MIDI '
1 'PCR 1 '
```

In the following example, the USB keyboard which is listed above as client 24 will be connected to a Csound synthesizer which is listening on the first VirMIDI port. The keyboard has three output ports. The first (24:0) transmits messages received on the MIDI in port, the second (24:1) transmits keyboard and controller messages, and the third (24:2) transmits system exclusive messages. The following command connects the second port of the keyboard to the Csound synthesizer:

```
aconnect 24:1 20:0
```

Remember that Csound acts as a raw MIDI device and is not an ALSA sequencer client. This means that Csound will not appear in MIDI device listings and will not be available for use directly with *aconnect*, so you must connect to a virtual device (like 'virtual raw MIDI' or 'MIDI through') for persistent connections, or connect directly to the destination using command line flags.

## MIDI Output (Raw Midi driver)

Csound can be connected to any device which shows up on the ALSA sequencer list of output ports, obtained by "amidi -l" as above. In order to connect a Csound synthesizer to the MIDI out port of the keyboard listed above, the following flag would be used:

```
-Qhw:2,0,0
```

## MIDI Input and Output (Midi Sequencer driver)

This driver is to be preferred over the Raw Midi driver. It has these advantages:

- Multiple concurrent access.
- Scheduled by priority queues.
- Real-time event dispatching i.e., the role of the Midi Sequencer is to deliver events at the right time (sequence) to the right destination (device).

The following command will call the Midi Sequencer. Here it listens to midi port 20. The midi output port is also 20:

```
+rtmidi=alsaseq -M20 -Q20
```

Csound will automatically create its own ALSA sequencer port. For a list of available devices, use the following command:

```
aconnect -i -o
```

This will create output that will look something like the following:

```
client 0: 'System' [type=kernel]
0 'Timer '
1 'Announce '
client 14: 'Midi Through' [type=kernel]
```

```
0 'Midi Through Port-0'  
client 20: 'M Audio Delta 1010' [type=kernel]  
0 'M Audio Delta 1010 MIDI'  
client 130: 'Csound' [type=user]  
0 'Csound'
```

The output of Csound will contain lines like:

```
.....  
ALSASEQ: opened MIDI output sequencer  
ALSASEQ: created output port 'Csound' 130:0  
ALSASEQ: connected to 20:0  
.....  
.....  
ALSASEQ: opened MIDI input sequencer  
ALSASEQ: created input port 'Csound' 130:0  
ALSASEQ: connected from 20:0  
.....
```

## Scheduling

If you are able to run Csound as the root user, using the "--sched" flag will dramatically improve real-time performance, when using ALSA, however you may hang your system if you do something stupid. DO NOT use "--sched" if you are using JACK for audio output. JACK controls scheduling for the audio applications connected to it, and also tries to run at the highest possible priority. If the "--sched" flag is used, Csound and JACK will be competing rather than cooperating, resulting in extremely poor performance.

## Using JACK

The simplest way to use the JACK plugin enabling input and output is as follows:

```
-+rtaudio=jack -i adc -o dac
```

Additionally, there are some command line options specific to JACK:

### JACK Command-line Flags

**-+jack\_client=[client\_name]**

The client name used by Csound, defaults to 'csound5'. If multiple instances of Csound connect to the JACK server, different client names need to be used to avoid name conflicts.

**-+jack\_inportname=[input port name prefix], -+jack\_outportname=[output port name prefix]**

Name prefix of Csound JACK input/output ports; the default is 'input' and 'output'. The actual port name is the channel number appended to the name prefix. Example: with the above default settings, a stereo orchestra will create these ports in full duplex operation:

|                 |                  |
|-----------------|------------------|
| csound5:input1  | (record left)    |
| csound5:input2  | (record right)   |
| csound5:output1 | (playback left)  |
| csound5:output2 | (playback right) |

-+jack\_sleep\_time=[sleep time in microseconds] As of Csound version 5.01, this option is deprecated and ignored.

## Connecting Csound to other JACK clients

By default, no connections are made (you need to use jack\_connect, qjackctl, or a similar utility); however, the plugin can connect to ports specified as '-iadc:portname\_prefix' or '-odac:portname\_prefix', where portname\_prefix is the full name of a port without a channel number, such as 'alsa\_pcm:capture\_' (for -i adc), or 'alsa\_pcm:playback\_' (for -o dac).

## Notes on buffer sizes

Audio data is received from and sent to the JACK server by Csound using a ring buffer that is controlled by the -b and -B flags. -B is the total size of the buffer, while -b is the size of a single period. These values are rounded so that the total size is an integer multiple of, and greater than the period size. The difference of the Csound buffer and period size must be greater than or equal to the JACK period size.

If both -iadc and -odac are used at the same time, the -b option should be set to an integer multiple of ksmmps.

An example of buffer settings for low latency on a fast system:

```
jackd -d alsa -P -r 48000 -p 64 -n 4 -zt &
csound -+rtaudio=jack -b 64 -B 256 [...]
```

with real time scheduling (as root):

```
jackd -R -P 90 -d alsa -P -r 48000 -p 64 -n 2 -zt &
csound --sched=80,90,10 -d -+rtaudio=jack -b 64 -B 192 [...]
```

To improve performance, use ksmmps values like 32 and 64.

The sample rate of the orchestra must be the same as that of the JACK server.

## Using Pulseaudio

Support for Pulseaudio [<http://www.pulseaudio.org/>] was added in Csound 5.09. You can specify the following settings:

1. Sink names: it's possible to use a number instead of the full name, so -odac:1 would select your second device (count starts at 0).
2. Server name: it's possible to connect to a specific server by using -+server=<server\_string> where server\_string is a name of a server or a more complex server selection string (see [pulseaudio.org](http://www.pulseaudio.org/) [<http://www.pulseaudio.org/>] on server strings). This should be network transparent and should allow connections to remote machines.
3. Stream names: it is possible to label the streams generated by csound, by using -+output\_stream=<stream-name> and -+input\_stream=<stream-name>

Here's an example command line:

```
csound -odac:1 examples/trapped.csd -+rtaudio=pulse -+server=unix:/tmp/pulse-victor/native -+output_stream=trapped
```

# Windows

## Real-time Audio

Windows users can use either the default *PortAudio* Realtime module, or the *winmm* Realtime Audio Module. The *winmm* module is a native windows module which provides great stability, but latency will usually be too high for realtime interaction. To activate a realtime module, you can use the *-+rtaudio* flag with value of *portaudio* or *winmme*. The default value is *portaudio*, which is activated by default without specifying it.

You also need to specify the sound device you want to use, and specify that you want to generate realtime audio output instead of soundfile to disk output. To do this, you must use the *-odac* or *-o dac* flag, which tells csound to output to the Digital-to-Analog converters instead of a file. By adding a number after the flag (e.g. *-odac2*), you can choose the device number you want. To find out available devices in your system, you can use a large out of range number (e.g. *-odac99*), and csound will report an error, and list available devices.

When choosing the device number under Portaudio, you are also choosing the driver interface, since Portaudio supports WinMME, DirectX and ASIO. If you have an ASIO capable interface or an ASIO driver emulator like ASIO4ALL [<http://wwwasio4all.com>], the device will show multiple times, once for each driver interface. ASIO will give you the best latency on your system, so if available it should be your choice for realtime audio output.

Enabling realtime audio input is done using *-iadc*, which makes csound listen to the realtime audio outputs. You can again select the device by its number, and check for available devices using an out of range number. Note that for input you use 'adc' instead of 'dac'. Make sure you have the appropriate input selected in your soundcard's control panel.

## Real-time MIDI

To enable Real-time MIDI on Windows, you can use the *-M* flag for MIDI input and the *-Q* flag for MIDI output. You might need to specify the device number after the flag (e.g. *-M2*), and again, you can find the available devices by giving an out of range number.

Csound will use PortMidi as the default MIDI module, but there's also a native *winmme* module, which can be activated with the flag:

```
-+rtmidi=winmme
```

A typical set of flags to enable Real-time Audio and MIDI I/O can look like:

```
-+rtmidi=winmme -M1 -Q1 -+rtaudio=portaudio -odac3 -iadc3
```

# Mac OSX

## Real-time Audio

OSX users can use either the *PortAudio* (default),*auhal*(or *coreaudio*), or the *Jack* realtime audio modules. The *auhal* module is a native OSX module which provides good latency, but it might not work with

some external hardware. The Jack module can be used for interconnecting with other applications, but you will need to install the JackOSX software in order to use it. To activate a realtime module, you can use the `-+rtaudio` flag with value of *portaudio*, *auhal*, or *jack*. The default value is *portaudio*, which is activated by default without specifying it.

You also need to specify the sound device you want to use, and specify that you want to generate real-time audio output instead of soundfile to disk output. To do this, you must use the `-odac` or `-o dac` flag, which tells csound to output to the Digital-to-Analog converters instead of a file. By adding a number after the flag (e.g. `-odac2`), you can choose the device number you want. To find out available devices in your system, you can use a large out of range number (e.g. `-odac99`), and Csound will report an error, and list available devices. This numbering convention works for portaudio and auhal, but for Jack, you will need to pass the name of the desired output device after a colon (e.g. `-odac:system:playback_`).

Enabling realtime audio input is done using `-iadc`, which makes csound listen to the realtime audio inputs. You can again select the device by its number (or name), and check for available devices using an out of range number. Note that for input you use 'adc' instead of 'dac'. Make sure you have the appropriate input selected in your soundcard's control panel.

## Real-time MIDI

To enable Real-time MIDI on OSX, you can use the `-M` flag for MIDI input and the `-Q` flag for MIDI output. You might need to specify the device number after the flag (e.g. `-M2`), and again, you can find the available devices by giving an out of range number.

Csound will use PortMidi as the default MIDI module, but there's also a native coremidi module, which can be activated with the flag:

```
-+rtmidi=cmidi
```

The coremidi module currently only supports MIDI input.

A typical set of flags to enable Real-time Audio and MIDI I/O can look like:

```
-+rtmidi=cmidi -M1 -+rtaudio=auhal-odac3 -iadc3
```

## Optimizing Audio I/O Latency

To achieve the lowest latency possible without audio break ups, a combination of variables needs to be tweaked. The final values will be platform and system dependent, and will also depend on the complexity of the audio calculations performed. You need to adjust *ksmps* in the orchestra, as well as the software (*-b*) and hardware buffer (*-B*) sizes.

Usually the simplest solution is the following:

1. Set *ksmps* to a value with a good tradeoff between quality and performance, without adjusting *-B* at all.
2. Set *-b* to a negative power of two of this value.

To get the optimal values, start with something you think is going to be too low, ie `-1`, and then continue "upwards", `-2`, `-4` and so on, until you stop getting x-runs (glitches). The real value of *-b* will be

the absolute value of  $-b * ksmmps$ .

3. Reduce the hardware buffer ( $-B$ ). Bring it down from the default (1024 on Linux, 4096 on Mac OS X, 16384 on Windows), halving it each time, until you start to get x-runs (glitches) again. Then take it back up again until performance is continuous.

This process assumes you have a 16-bit soundcard. If you have a 24-bit soundcard, then  $-B$  should be 3/2, or 3 times  $-b$ , rather than 2 or 4 times. Csound works with 32-bit floats, or 64-bit doubles whereas most soundcards are 16 or 24-bit integer.  $-b$  is the internal buffer, so it's dealing with the 32 or 64-bit side of things, whereas  $-B$  is the hardware buffer, so it's dealing with the 16 or 24-bit side. The csound default for floats is  $-B = 4 * -b$ . This is a sane value for a 16 bit card. You can usually get away with  $-B = 2 * -b$ , but this is the absolute minimum. For example, if you set  $-b1024 -B2048$ , csound will tell you that:

```
audio buffered in 1024 sample-frame blocks  
writing 4096-byte blocks to dac
```

4096 bytes is 32768 bits.  $32768/32 = 1024$ , our sample-frame size,  $1024 * 32/16 = 2048$ , our buffer size. Were we to reduce the value of  $-B$ , we would need to reduce the value of  $-b$  by a corresponding amount in order to continue to write 16-bit integers to dac. The minimum size of  $-b$  is  $(-B * bitrate)/32$ . That is to say that the minimum ratio of  $-b$  to  $-B$  should be:

- 16-bit: 1:2
- 24-bit: 2:3
- 32-bit: 1:1

While there is no theoretical maximum ratio, it makes no sense to have a very high ratio here, as the software buffer has to fill the hardware buffer before returning. If the ratio is high, it will take a long time, defeating the purpose of setting a small value for  $-b$ .

The value of  $-b$  is something that will need to be varied depending on the complexity of the instrument you're working with, but because it's intimately related to the value of  $ksmps$ , it's better to synchronise it with  $ksmps$  and go from there. One way to do it is to decide how long the release on your envelopes might need to be at maximum (for desired effect), set the release on all envelopes to maximum, give yourself a generous value for  $-b$ , and then play. If it breaks up, double  $ksmps$ , repeat until smooth, then bring the value of  $-b$  down as far as possible.

The value of  $-B$  is primarily determined by operating system and soundcard. Figure out (using above method) how low you can go, and use that value (or one higher for safety). If you have problems you'll know that it's probably because of an inappropriate value for  $ksmps$ , too low a value for  $-b$ , or denormals (see *denorm*).

---

# Configuring

Once you have either unpacked a binary distribution, or built Csound from sources, you will need to configure Csound so that it will run properly on your system. Installers usually perform these steps for you automatically.

On all platforms, make sure the directory or directories containing Csound's plugin libraries are in an `OPCODE6DIR` or `OPCODE6DIR64` environment variable depending on the precision of the compiled binary. (Note that for csound5 these environment variables were `OPCODEDIR` and `OPCODEDIR64`.)

The Python opcodes currently require at least Python 2.4, which can be downloaded from [www.python.org](http://www.python.org) [<http://www.python.org>] if it is not already on your system. You can check if it is available by typing 'python' on a command prompt or DOS window.

## Windows

On Windows, make sure the directory or directories (normally the `C:\Program Files\Csound` directory) containing the Csound executables directory are in your `PATH` variable, or else copy all the executable files to your Windows `system32` directory. Depending on your installation method, you might also need to set the `OPCODE6DIR` and `OPCODE6DIR64` environment variables. Assuming that Csound is installed to the default location of `C:\Program Files\Csound` you can use (otherwise set the paths accordingly):

```
set OPCODE6DIR=C:\Program Files\Csound\plugins  
set OPCODE6DIR64=C:\Program Files\Csound\plugins64  
set PATH=%PATH%;C:\Program Files\Csound\bin
```

### Missing python24.dll or python25.dll

If you get a pop-up about the missing Python library (`python24.dll` or `python25.dll`) and don't need the Python opcodes, just delete `C:\Program Files\Csound\plugins\py.dll` and `C:\Program Files\Csound\plugins64\py.dll`, and the pop-up about the missing Python library should be gone.

## Unix and Linux

On Unix and Linux, either install the Csound program in one of the system `bin` directories, typically `/usr/local/bin`, and the Csound and plugin shared libraries in places like `/usr/local/lib/csound/plugins` or `/usr/local/lib/csound/plugins64` and make sure that `OPCODE6DIR` and `OPCODE6DIR64` environment variable are set correctly.

## CsoundAC

CsoundAC requires some additional configuration. On all platforms, CsoundAC requires that you have Python installed on your computer. The directory containing the `_csoundAC` shared library and the `CsoundAC.py` file must be in your `PYTHONPATH` environment variable, so that the Python runtime knows how to load these files.

---

# Syntax of the Orchestra

The Csound orchestra (.orc) or the *<CsInstruments>* section of a csd file, contains:

- A *header section*, which specifies global options for instrument performance
- A list of *User defined opcodes* and *instrument blocks* containing UDO and instrument definitions.

The orchestra header, instrument blocks, and UDOs contain *Orchestra statements*. An *orchestra statement* in Csound has the format:

```
label:    result opcode argument1, argument2, ... ;comments
```

The label is optional and identifies the basic statement that follows as the potential target of a go-to operation (see *Program Flow Control*). A label has no effect on the statement per se.

Depending on their function, some opcodes produce no output, so they have no result value. Others take no arguments and only produce a result.

Every orchestra statement must be on a single line, however long lines can be wrapped to a new line using the '\' character. This character indicates that the next line is part of the current one, this way you can split a line for easier reading, like this:

```
a2 oscbnk kcps, 1.0, kfmd1, 0.0, 40, 203, 0.1, 0.2, kamfr, kamfr2, 148, \
0, 0, 0, 0, 0, 0, -1,
kfnr, 3, 4
```

Comments are optional and are for the purpose of letting the user document his orchestra code. Comments begin with a semicolon (;) and extend to the end of the line. Comments can optionally be in C-style, spanning multiple lines like this:

```
/* Anything in here -----
   is a comment which can span
   several lines ----- */
```

The remainder (result, opcode, and arguments) form the basic statement. This also is optional, i.e. a line may have only a label or comment or be entirely blank. If present, the basic statement must be complete on one line, and is terminated by a carriage return and line feed.

The opcode determines the operation to be performed; it usually takes some number of input values (or arguments, with a maximum value of about 800); and it usually has a result field variable to which it sends output values at some fixed rate. There are four possible rates:

1. once only, at orchestra setup time (effectively a permanent assignment)
2. once at the beginning of each note (at initialization (init) time: i-rate)
3. once every performance-time control loop (perf-time control rate, or k-rate)
4. once each sound sample of every control loop (perf-time audio rate, or a-rate)

# Orchestra Header Statements

The *Orchestra Header* contains global information that applies to all instruments and defines aspects of Csound output. It is sometimes referred to as *instr 0*, because it behaves as an instrument, but without k- or a-rate processing (i.e. only opcodes and instructions that work at i-rate are allowed).

An *orchestra header statement* operates once only, at orchestra setup time. It is most commonly an assignment of some value to a *global reserved symbol*, e.g. sr = 20000. All orchestra header statements belong to a pseudo instrument 0, an *init* pass of which is run prior to all other instruments at score time 0. Any *ordinary statement* can serve as an orchestra header statement, eg. gifreq = cpspch(8.09) provided it is an init-time only operation. Statements that are normally placed in an orchestra header are:

- *0dbfs*
- *ctrlinit*
- *ftgen*
- *kr*
- *ksmps*
- *massign*
- *nchnls*
- *pgmassign*
- *pset*
- *seed*
- *sr*
- *strset*

For example, a Csound header may look like:

```
sr = 44100
kr = 4410
ksmps = 10
nchnls = 2
0dbfs = 1

massign 1, 10
```

# Instrument and Opcode Block Statements

An instrument block is comprised of *ordinary statements* that set values, control the logical flow, or invoke the various signal processing subroutines that lead to audio output. Statements that define an instrument block are:

- *instr*
- *endin*

An instrument block looks like this:

```
instr 1 ;A simple sine wave oscillator
aout oscils 10000, 440, 0
out aout
endin
```

Statements that define a user defined opcode (UDO) block are

- *opcode*
- *endop*

See the *UDO* section for more information.

## Ordinary Statements

An *ordinary statement* runs at either init time or performance time or both. Operations which produce a result formally run at the rate of that result (that is, at init time for i-rate results; at performance time for k- and a-rate results), with the sole exception of the *init* opcode. Most generators and modifiers, however, produce signals that depend not only on the instantaneous value of their arguments but also on some preserved internal state. These performance-time units therefore have an implicit init-time component to set up that state. The run time of an operation which produces no result is apparent in the opcode.

Arguments are values that are sent to an operation. Most arguments will accept arithmetic expressions composed of constants, variables, reserved symbols, value converters, arithmetic operations, and conditional values.

## Types, Constants and Variables

*Constants* are floating point numbers, such as 1, 3.14159, or -73.45. They are available continuously and do not change in value.

*Variables* are named cells containing numbers. They are available continuously and may be updated at one of the four update rates (setup only, i-rate, k-rate, or a-rate). i- and k-rate variables are scalars (i.e. they take on only one value at any given time) and are primarily used to store and recall controlling data, that is, data that changes at the note rate (for i-rate variables) or at the control rate (for k-rate variables). i- and k-variables are therefore useful for storing note parameter values, pitches, durations, slow-moving frequencies, vibratos, etc. a-rate variables, on the other hand, are arrays or vectors of information. Though renewed on the same perf-time control pass as k-rate variables, these array cells represent a finer resolution of time by dividing the control period into sample periods (see *ksmps*). a-rate variables are used to store and recall data changing at the audio sampling rate (e.g. output signals of oscillators, filters, etc.).

Some types of variables can be thought of as signals. For example a-rate and k-rate variables are signals that have a constant update frequency (see *kr* and *sr*). This abstraction is generally quite useful, but be aware that a-rate signals are actually vectors which are processed at k-rate, i.e. Csound works at k-rate internally but processes *ksmps* number samples for each a-rate variable on every control pass.

There are other types of signals that require rates that don't match *kr* or *sr*. f-rate and w-rate signals are used for spectral processing and their rate is determined by the window size and overlap factor.

A further distinction is that between local and global variables. *local* variables are private to a particular instrument, and cannot be read from or written into by any other instrument. Their values are preserved, and they may carry information from pass to pass (e.g. from initialization time to performance time)

within a single instrument. Local variable names begin with the letter *p*, *i*, *k*, or *a*. The same local variable name may appear in two or more different instrument blocks without conflict.

*Global* variables are cells that are accessible by all instruments. The names are either like local names preceded by the letter *g*, or are special reserved symbols. Global variables are used for broadcasting general values, for communicating between instruments (semaphores), or for sending sound from one instrument to another (e.g. mixing prior to reverberation).

Given these distinctions, there are nine forms of local and global variables:

**Table 3. Types of Variables**

| Type                          | When Renewable                                 | Local    | Global  |
|-------------------------------|--|----------|---------|
| reserved symbols              | permanent                                      | --       | rsymbol |
| score pfields                 | i-time   | p number | --      |
| init variables                | i-time   | i name   | gi name |
| control signals               | p-time, k-rate                                 | k name   | gk name |
| audio signals                 | p-time, k-rate (all audio samples in a k-pass) | a name   | ga name |
| spectral data types           | k-rate   | w name   | --      |
| streaming spectral data types | k-rate   | f name   | gf name |
| string variables              | i-time and optionally k-rate                   | S name   | gS name |
| vector variables              | k-rate   | t name   |         |

Where *rsymbol* is a special reserved symbol (e.g. *sr*, *kr*), *number* is a positive integer referring to a score pfield or sequence number, and *name* is a string of letters, the underscore character, and/or digits with local or global meaning. As might be apparent, score parameters are local i-rate variables whose values are copied from the invoking score statement just prior to the init pass through an instrument, while MIDI controllers are variables which can be updated asynchronously from a MIDI file or MIDI device.

## Variable Initialization

Opcodes that let one initialize variables are:

- *assign*
- *divz*
- *init*
- *tival*

## Predefined Math Constant Macros

Csound defines several important math constants as *Macros*. You can see the full list [here](#).

## Expressions

Expressions may be composed to any depth. Each part of an expression is evaluated at its own proper rate. For instance, if the terms within a sub-expression all change at the control rate or slower, the sub-expression will be evaluated only at the control rate; that result might then be used in an audio-rate evaluation. For example, in

```
k1 + abs(int(p5) + frac(p5) * 100/12 + sqrt(k1))
```

the 100/12 would be evaluated at orch init, the p5 expressions evaluated at note i-time, and the remainder of the expression evaluated every k-period. The whole might occur in a unit generator argument position, or be part of an assignment statement.

## Directories and Files

Many generators and the Csound command itself specify filenames to be read from or written to. These are optionally full pathnames, whose target directory is fully specified. When not a full path, filenames are sought in several directories in order, depending on their type and on the setting of certain environment variables. The latter are optional, but they can serve to partition and organize the directories so that source files can be shared rather than duplicated in several user directories. The environment variables can define directories for soundfiles *SFDIR*, sound samples *SSDIR*, sound analysis *SADIR*, and include files for orchestra and score files *INCDIR*.

In Csound version 5.00 and later, these environment variables can specify multiple directories as a ; separated list. If a file is found in more than one location, the first one has the highest precedence.

The search order is:

1. Soundfiles being written are placed in *SFDIR* (if it exists), else the current directory.
2. Soundfiles for reading are sought in the current directory. If default paths are not disabled, files will next be sought for relative to the CSD/ORC/SCO file. Finally they will be sought in *SSDIR* and then *SFDIR*.
3. Analysis control files for reading are sought in the current directory. If default paths are not disabled, files will next be sought for relative to the CSD/ORC/SCO file. Finally they will be sought in *SADIR*.
4. MIDI files for reading are sought in the current directory. If default paths are not disabled, files will next be sought for relative to the CSD/ORC/SCO file. Finally they will be sought in *MFDIR*, *SSDIR* and *SFDIR*.
5. Files of code to be included in orchestra and score files (with *#include*) are sought first in the current directory, then in the same directory as the orchestra or score file (as appropriate), then finally *INCDIR*.

## Nomenclature

Throughout this document, opcodes are indicated in **boldface** and their argument and result mnemonics, when mentioned in the text, are given in *italics*. Argument names are generally mnemonic (*amp*, *phs*), and the result is usually denoted by the letter *r*. Both are preceded by a type qualifier *i*, *k*, *a*, or *x* (e.g. *kamp*, *iphhs*, *ar*). The prefix *i* denotes scalar values valid at note init time; prefixes *k* or *a* denote control (scalar) and audio (vector) values, modified and referenced continuously throughout performance (i.e. at every control period while the instrument is active). Arguments are used at the prefix-listed times; res-

ults are created at their listed times, then remain available for use as inputs elsewhere. With few exceptions, argument rates may not exceed the rate of the result. The validity of inputs is defined by the following:

- arguments with prefix *i* must be valid at init time;
- arguments with prefix *k* can be either control or init values (which remain valid);
- arguments with prefix *a* must be vector inputs;
- arguments with prefix *x* may be either vector or scalar (the compiler will distinguish).

All arguments, unless otherwise stated, can be expressions whose results conform to the above. Most opcodes (such as **linen** and **oscil**) can be used in more than one mode, which one being determined by the prefix of the result symbol.

Throughout this manual, the term "opcode" is used to indicate a command that usually produces an a-, k-, or i-rate output, and always forms the basis of a complete Csound orchestra statement. Items such as "+" or "sin(x)" or, "( a >= b ? c : d)" are called "operators."

## Macros

Orchestra macros work like C preprocessor macros, and replace the content of the macro in the orchestra before it is compiled. The opcodes one can use to create, call, or undefine orchestra macros are:

- `#define`
- `$NAME`
- `#ifdef`
- `#ifndef`
- `#end`
- `#else`
- `#include`
- `#undef`

Orchestra macros can also be defined using the command line flag `--omacro:`.

More information and examples on the usage of orchestra macros can be found in the entry for `#define`.

These opcodes refer to orchestra macros; for score macros, refer to *Score Macros*.

## Named Instruments

As a recent addition to the orchestra syntax, instruments can be defined with string names. Such named instruments are callable from the score, and are supported by a number of opcodes.

## Syntax

---

A named instrument is declared as shown below:

```
instr Name[, Name2[, Name3[, ...]]]  
[...]  
endin
```

A single instrument can have any number of names, and any of these names can be used to call the instrument. Additionally, it is possible to use numbers as name, denoting a standard numbered instrument, so the following declaration is also valid:

```
instr 100, Name1, 99, Name2, 1, 2, 3
```

An instrument name may consist of any number of letters, digits, and the underscore (\_) character, however, the first character must not be a digit. Optionally, the instrument name may be prefixed with the '+' character (see below), for example:

```
instr +Reverb
```

For all instrument names, a number is automatically assigned (note: if the message level (-m) is not zero, these numbers are printed to the console during orchestra compilation), following these rules:

- any unused instrument numbers are taken up in ascending order, starting from 1
- the numbers are assigned in the order of instrument name definition, so named instruments that are defined later will always have a higher number (except if the '+' modifier is used)
- if the instrument name was prefixed with '+', the assigned number will be higher than that of any of the (both numbered and named) other instruments without '+'. If there are multiple '+' instruments, the numbering of these will follow the order of definition, according to the above rule.

Using '+' is mainly useful for global output or effect instruments, that must be performed after the other instruments.

An example for instrument numbers:

```
instr 1, 2  
endin  
  
instr Instr1  
endin  
  
instr +Effect1, Instr2  
endin  
  
instr 100, Instr3, +Effect2, Instr4, 5  
endin
```

In this example, the instrument numbers are assigned as follows:

```
Instr1: 3  
Effect1: 101  
Instr2: 4  
Instr3: 6  
Effect2: 102  
Instr4: 7
```

# Using Named Instruments

Named instruments can be called by using the name in double quotes as the instrument number (note: the '+' character should be omitted). Currently (as of Csound 4.22.4), named instruments are supported by:

- 'i' and 'q' score events

## Notes

1. in score files, unmatched quotes, and spaces or other invalid characters in the strings should be avoided, otherwise (at least with current version) unpredictable behavior may occur (this problem does not exist for -L line events). However, there is checking for undefined instruments, and in such cases, the event is simply ignored with a warning.
  2. Stand-alone utilities (score sort and extract) do not support named instruments. It is still possible to sort such scores by using the -t0 option of the main Csound executable)
- real-time line events (-L)
  - event, schedkwhen, subinstr, and subinstrinit opcodes
  - massign, pgmassign, prealloc, and mute opcodes

Additionaly, there is a new opcode (nstrnum) that returns the number of a named instrument:

```
insno nstrnum "name"
```

With the above example, nstrnum "Effect1" would return 101. If an instrument with the specified name does not exist, an init error occurs, and -1 is returned.

## Example

```
; ---- orchestra ----

sr      =  44100
ksmps   =  10
nchnls  =  1

prealloc "SineWave", 20
prealloc "MIDISineWave", 20

massign 1, "MIDISineWave"

gaOutSend    init 0
    instr +OutputInstr
    out gaOutSend
    clear gaOutSend
endin

instr SineWave
a1    oscils p4, p5, 0
vincr gaOutSend, a1
endin
```

```
        instr MIDISineWave
iamp    veloc
inote   notnum
icps    = cpsoct(inote / 12 + 3)
a1      oscils iamp * 100, icps, 0
        vincr gaOutSend, a1
        endin

; ---- score ----

i "SineWave" 0 2 12000 440
i "OutputInstr" 0 3
e
```

## User Defined Opcodes (UDO)

Csound allows the definition of opcodes inside the orchestra header using the opcodes *opcode* and *endop*. The defined opcode may run with a different number of control samples (*ksmps*) using *setksmps*.

To connect inputs and outputs for the UDO, use *xin* and *xout*.

An UDO looks like this:

```
opcode Lowpass, a, akk
setksmps 1           ; need sr=kr
ain, ka1, ka2  xin       ; read input parameters
aout  init 0          ; initialize output
aout    = ain*ka1 + aout*ka2 ; simple tone-like filter
        xout aout        ; write output
endop
```

This UDO called *Lowpass* takes 3 inputs (the first is a-rate, and the next two are k-rate), and delivers 1 a-rate output. Notice the use of *xin* to receive inputs and *xout* to deliver outputs. Also note the use of *setksmps*, which is needed for the filter to work properly.

To use this UDO within an instrument, you would do something like:

```
afiltered Lowpass asource, kvalue1, kvalue2
```

See the entry for *opcode* for detailed information on UDO definition.

You can find many ready made UDO's (or contribute your own) at *Csounds.com* [<http://www.csounds.com/>]'s *User Defined Opcode Database* [<http://www.csounds.com/udo/>].

## K-Rate Vectors

Csound allows the declaration and deployment of one-dimensional vectors or tables. They are local to an instrument, and need to be declared for size (with the *init* opcode). Individual elements are read as part of any expression with square brackets to give an index at k-rate. Individual elements can be assigned, and there are a number of opcodes to query and modify tables.

# Function Syntax in Csound6

Csound 6 has introduced a new alternative syntax for orchestra code. This is initially an experimental feature, which has some limitations, as explained below. It will also allow the introduction of some non-backwards-compatible language features.

## Overview

The main aspect of the new syntax is that some opcodes can be called as functions, and inlined in orchestra code. The general form of this is the expression:

```
var* = op(exprlist*)
```

where \* indicates optional, var is a single variable in one of Csound6 types, and exprlist is a comma separated list of expressions (or a single expression or variable). These expressions can be placed anywhere inside instrument or opcode blocks. I-time operations can also be placed outside instrument blocks. The functional syntax can be intermixed with standard Csound code.

Here are some examples of these expressions:

```
a1 = oscil(p4,p5)
out(vco2(p4*linen(1,0.1,p3,0.1),p5)
outs(oscili(in(),p5), in())
```

## Limitations

The main limitation is that only opcodes with single outputs (or no outputs) are allowed. In addition, opcodes with multiple optional outputs will not be parsed successfully in this form. An alternative to allow for these is to wrap them in user-defined opcodes, or just to intermix standard Csound syntax with this new style.

To resolve opcode ambiguities, we have introduced type annotations, in the form of op:type(exprlist). For instance the code:

```
a1 = oscili(oscili:k(p4,p5), 440)
```

will choose a control-rate opcode to modulate the amplitude of the audio carrier, rather than an audio rate one. There will be cases where the type annotation will be required, when the input arguments cannot be used to determine the correct type of opcode to be applied.

---

# The Standard Numeric Score

The score section contains events that instantiate instruments from the orchestra. There are various score statements that enable complex score building within the csound language.

Currently, the maximum length of the score depends on the platform's architecture; on a 32bit system this is  $2^{31}-1$  control periods; so for example, with kr=1500, you can run a score for a maximum of about 16.5 days before problems occur due to overflowing signed 32-bit integer variables. On a 64bit machine the same condition would be just about 9 billion years. The input token 'z' is read as a number with the value of approximately 25367 years.

Note also that when using single precision floats (i.e. the 'f' installers rather than the 'd' ones), the accuracy of timing becomes worse after performing for a long time.

## Preprocessing of Standard Scores

A *Score* (a collection of score statements) is divided into time-ordered sections by the *s statement*. Before being read by the orchestra, a score is preprocessed one section at a time. Each section is normally processed by 3 routines: *Carry*, *Tempo*, and *Sort*.

### Carry

Within a group of consecutive *i statements* whose p1 whole numbers correspond, any pfield left empty will take its value from the same pfield of the preceding statement. An empty pfield can be denoted by a single point(.) delimited by spaces. No point is required after the last nonempty pfield. The output of Carry preprocessing will show the carried values explicitly. The Carry Feature is not affected by intervening comments or blank lines; it is turned off only by a non-*i statement* or by an *i statement* with unlike p1 whole number.

Three additional features are available for p2 alone: +, ^+x, and ^-x. The symbol + in p2 will be given the value of p2 + p3 from the preceding i statement. This enables note action times to be automatically determined from the sum of preceding durations. The + symbol can itself be carried. It is legal only in p2. E.g.: the statements

```
  i1    0      .5      100  
  i1    .      +  
  i1
```

will result in

```
  i1    0      .5      100  
  i1    .5      .5      100  
  i1    1      .5      100
```

The symbols ^+x and ^-x determine the current p2 by adding or subtracting, respectively, the value of x from the preceding p2. These may be used in p2 only and are *not* carried like the + symbol. Note also that there should be no spaces following the ^, the +, or the - parts of these symbols -- the number must come directly after as in ^+2.3. If the example above had been

```
i1    0      .5      100
i .   ^+1
i .   ^+1
```

the result would instead be

```
i1    0      .5      100
i1    1      .5      100
i1    2      .5      100
```

The Carry feature should be used liberally. Its use, especially in large scores, can greatly reduce input typing and will simplify later changes.

There can sometimes be circumstances where you do not want "missing" pfields after the last one entered to be implicitly carried. An example would be an instrument that is designed to take a variable number of pfields. Beginning with Csound 5.08, you can prevent the implicit carrying of pfields at the end of an i statement by using the symbol ! (called the "no-carry symbol"). The ! must appear at the end of an i statement and it cannot be used in p1, p2, or p3, since these pfields are required. Here is an example:

```
i1    0      .5      100
i .   +
i .   .      .
i     !
```

This score would be interpreted as

```
i1    0      .5      100
i1    .5     .5      100
i1    1      .5      ; no p4
i1    1.5    .5      ; only p1 to p3 are carried here
```

## Tempo

This operation time warps a score section according to the information in a *t statement*. The tempo operation converts p2 (and, for *i statements*, p3) from original beats into real seconds, since those are the units required by the orchestra. After time warping, score files will be seen to have orchestra-readable format demonstrated by the following:

```
i p1 p2beats p2seconds p3beats p3seconds p4 p5 ...
```

## Sort

This routine sorts all action-time statements into chronological order by p2 value. It also sorts coincident events into precedence order. Whenever an *f statement* and an *i statement* have the same p2 value, the *f statement* will precede. Whenever two or more *i statements* have the same p2 value, they will be sorted into ascending p1 value order. If they also have the same p1 value, they will be sorted into ascending p3 value order. Score sorting is done section by section (see *s statement*). Automatic sorting implies that score statements may appear in any order within a section.

## Note

The operations *Carry*, *Tempo* and *Sort* are combined in a 3-phase single pass over a score file, to produce a new file in orchestra-readable format ( see the *Tempo* example). Processing can be invoked either explicitly by the *Ssort* command, or implicitly by *Csound* which processes the score before calling the orchestra. Source-format files and orchestra-readable files are both in ASCII character form, and may be either perused or further modified by standard text editors. User-written routines can be used to modify score files before or after the above processes, provided the final orchestra-readable statement format is not violated. Sections of different formats can be sequentially batched; and sections of like format can be merged for automatic sorting.

# Score Statements

The statements used in scores are:

- *a* - Advance score time by a specified amount
- *b* - Resets the clock
- *e* - Marks the end of the last section of the score
- *f* - Causes a *GEN subroutine* to place values in a stored function table
- *i* - Makes an instrument active at a specific time and for a certain duration
- *m* - Sets a named mark in the score
- *n* - Repeats a section
- *q* - Used to quiet an instrument
- *r* - Starts a repeated section
- *s* - Marks the end of a section
- *t* - Sets the tempo
- *v* - Provides for locally variable time warping of score events
- *x* - Skip the rest of the current section
- *y* - Set seed for random numbers, either from *p1* or, if omitted, the clock
- *{* - Begins a non-sectional, nestable loop.
- *}* - Ends a non-sectional, nestable loop.

# Next-P and Previous-P Symbols

At the close of any of the operations *Carry*, *Tempo*, and *Sort*, three additional score features are interpreted during file writeout: next-p, previous-p, and *ramping*.

*i statement* pfields containing the symbols *npx* or *ppx* (where *x* is some integer) will be replaced by the

appropriate pfield value found on the next i statement (or previous i statement) that has the same p1. For example, the symbol *np7* will be replaced by the value found in p7 of the next note that is to be played by this instrument. *np* and *pp* symbols are recursive and can reference other *np* and *pp* symbols which can reference others, etc. References must eventually terminate in a real number or a *ramp symbol*. Closed loop references should be avoided. *np* and *pp* symbols are illegal in p1, p2 and p3 (although they may reference these). *np* and *pp* symbols may be Carried. *np* and *pp* references cannot cross a Section boundary. Any forward or backward reference to a non-existent note-statement will be given the value zero.

E.g.: the statements

```
i1 0 1 10 np4 pp5
i1 1 1 20
i1 1 1 30
```

will result in

```
i1 0 1 10 20 0
i1 1 1 20 30 20
i1 2 1 30 0 30
```

*np* and *pp* symbols can provide an instrument with contextual knowledge of the score, enabling it to glissando or crescendo, for instance, toward the pitch or dynamic of some future event (which may or may not be immediately adjacent). Note that while the *Carry* feature will propagate *np* and *pp* through unsorted statements, the operation that interprets these symbols is acting on a fully sorted version of the score. The tempo operation is applied after the *pp* and/or *np* processing.

## Ramping

*i statement* pfields containing the symbol < will be replaced by values derived from linear interpolation of a time-based ramp. Ramps are anchored at each end by the first real number found in the same pfield of a preceding and following note played by the same instrument. E.g.: the statements

```
i1 0 1 100
i1 1 1 <
i1 2 1 <
i1 3 1 400
i1 4 1 <
i1 5 1 0
```

will result in

```
i1 0 1 100
i1 1 1 200
i1 2 1 300
i1 3 1 400
i1 4 1 200
i1 5 1 0
```

Ramps cannot cross a Section boundary. Ramps cannot be anchored by an *np* or *pp* symbol (although they may be referenced by these). Ramp symbols are illegal in p1, p2 and p3. Ramp symbols may be Carried. Note, however, that while the Carry feature will propagate ramp symbols through unsorted statements, the operation that interprets these symbols is acting on a time-warped and fully sorted ver-

sion of the score. In fact, time-based linear interpolation is based on warped score-time, so that a ramp which spans a group of accelerating notes will remain linear with respect to strict chronological time.

Starting with Csound version 3.52, using the symbols ( or ) will result in an exponential interpolation ramp, similar to *expon*. Using the symbol ~ (a tilde) will result in uniform, random distribution between the first and last values of the ramp. Use of these functions must follow the same rules as the linear ramp function.

## Score Macros

### Description

Macros are textual replacements which are made in the score as it is being presented to the system. The macro system in Csound is a very simple one, and uses the characters # and \$ to define and call macros. This can allow for simpler score writing, and provide an elementary alternative to full score generation systems. The score macro system is similar to, but independent of, the macro system in the orchestra language.

`#define NAME` -- defines a simple macro. The name of the macro must begin with a letter and can consist of any combination of letters and numbers. Case is significant. This form is limiting, in that the variable names are fixed. More flexibility can be obtained by using a macro with arguments, described below.

`#define NAME(a' b' c')` -- defines a macro with arguments. This can be used in more complex situations. The name of the macro must begin with a letter and can consist of any combination of letters and numbers. Within the replacement text, the arguments can be substituted by the form: \$A. In fact, the implementation defines the arguments as simple macros. There may be up to 5 arguments, and the names may be any choice of letters. Remember that case is significant in macro names.

`$NAME.` -- calls a defined macro. To use a macro, the name is used following a \$ character. The name is terminated by the first character which is neither a letter nor a number. If it is necessary for the name not to terminate with a space, a period, which will be ignored, can be used to terminate the name. The string, `$NAME.`, is replaced by the replacement text from the definition. The replacement text can also include macro calls.

`#undef NAME` -- undefines a macro name. If a macro is no longer required, it can be undefined with `#undef NAME`.

### Syntax

```
#define NAME # replacement text #
#define NAME(a' b' c') # replacement text #
$NAME.
#undef NAME
```

### Initialization

`# replacement text #` -- The replacement text is any character string (not containing a #) and can extend over multiple lines. The replacement text is enclosed within the # characters, which ensure that additional characters are not inadvertently captured.

### Performance

Some care is needed with textual replacement macros, as they can sometimes do strange things. They take no notice of any meaning, so spaces are significant. This is why, unlike the C programming language, the definition has the replacement text surrounded by # characters. Used carefully, this simple macro system is a powerful concept, but it can be abused.

**Another Use For Macros.** When writing a complex score it is sometimes all too easy to forget to what the various instrument numbers refer. One can use macros to give names to the numbers. For example

```
#define Flute  #i1#
#define Whoop  #i2#
$Flute. 0 10 4000 440
$Whoop. 5 1
```

## Examples

### Example 1. Simple Macro

A note-event has a set of p-fields which are repeated:

```
#define ARGS # 1.01 2.33 138#
i1 0 1 8.00 1000 $ARGS
i1 0 1 8.01 1500 $ARGS
i1 0 1 8.02 1200 $ARGS
i1 0 1 8.03 1000 $ARGS
```

This will get expanded before sorting into:

```
i1 0 1 8.00 1000 1.01 2.33 138
i1 0 1 8.01 1500 1.01 2.33 138
i1 0 1 8.02 1200 1.01 2.33 138
i1 0 1 8.03 1000 1.01 2.33 138
```

This can save typing, and makes revisions easier. If there were two sets of p-fields one could have a second macro (there is no real limit on the number of macros one can define).

```
#define ARGS1 # 1.01 2.33 138#
#define ARGS2 # 1.41 10.33 1.00#
i1 0 1 8.00 1000 $ARGS1
i1 0 1 8.01 1500 $ARGS2
i1 0 1 8.02 1200 $ARGS1
i1 0 1 8.03 1000 $ARGS2
```

### Example 2. Macros with arguments

```
#define ARG(A) # 2.345 1.03 $A 234.9#
i1 0 1 8.00 1000 $ARG(2.0)
```

```
i1 + 1 8.01 1200 $ARG(3.0)
```

which expands to

```
i1 0 1 8.00 1000 2.345 1.03 2.0 234.9  
i1 + 1 8.01 1200 2.345 1.03 3.0 234.9
```

## Multiple File Score

### Description

Using the score in more than one file.

### Syntax

```
#include "filename"
```

### Performance

It is sometimes convenient to have the score in more than one file. This use is supported by the *#include* facility which is part of the macro system. A line containing the text

```
#include "filename"
```

where the character " can be replaced by any suitable character. For most uses the double quote symbol will probably be the most convenient. The file name can include a full path.

This takes input from the named file until it ends, when input reverts to the previous input. There is currently a limit of 20 on the depth of included files and macros.

A suggested use of *#include* would be to define a set of macros which are part of the composer's style. It could also be used to provide repeated sections.

```
s  
#include :section1:  
; ; Repeat that  
s  
#include :section1:
```

Alternative methods of doing repeats, use the *r statement*, *m statement*, and *n statement*.

April, 1998 (New in Csound version 3.48)

Thanks to Luis Jure for pointing out the incorrect syntax in multiple file include statement.

## Evaluation of Expressions

In earlier versions of Csound the numbers presented in a score were used as given. There are occasions when some simple evaluation would be easier. This need is increased when there are macros. To assist in this area the syntax of arithmetic expressions within square brackets [ ] has been introduced. Expressions built from the operations +, -, \*, /, % ("modulo"), and ^ ("power of") are allowed, together with grouping with ( ). Unary minus and plus are also supported. The expressions can include numbers, and naturally macros whose values are numeric or arithmetic strings. All calculations are made in floating point numbers. The usual precedence rules are followed when evaluating: expressions within parentheses () are evaluated first and ^ is evaluated before \*, /, and % which are evaluated before + and -.

In addition to arithmetic operations, the following bitwise logical operators are also available: & (AND), | (OR), and # (XOR, exclusive-OR). These operators round their operands to the nearest (long) integer before evaluating. The logical operators have the same precedence as the \*, /, and % arithmetic operators.

Finally, the tilde symbol ~ can be used in an expression wherever a number is permissible to use. Each ~ will evaluate to a random value between zero (0) and one (1).

## Example

```
r3  CNT
i1  0   [0.3*$CNT.]
i1  +   [($CNT./3)+0.2]
e
```

As the three copies of the section have the macro \$CNT. with the different values of 1, 2 and 3, this expands to

```
s
i1  0   0.3
i1  0.3  0.533333
s
i1  0   0.6
i1  0.6  0.866667
s
i1  0   0.9
i1  0.9  1.2
e
```

This is an extreme form, but the evaluation system can be used to ensure that repeated sections are subtly different.

Here are some simple examples of each operator:

```
i1 0 1 [ 110 + 220 ] ; evaluates to 330
i1 +
. [ 330 - 55 ] ; 275
i1 +
. [ 44 * 10 ] ; 440
i1 +
. [ 1100 / 2 ] ; 550
i1 +
. [ 5 ^ 4 ] ; 625
i1 +
. [ 5660 % 1000 ] ; 660
i1 +
. [ 110 & 220 ] ; 76
i1 +
. [ 110 | 220 ] ; 254
i1 +
. [ 110 # 220 ] ; 178
i1 +
. [ ~ ] ; random between 0-1
i1 +
. [ ~ * 4 + 1 ] ; random between 1-5
i1 +
. [ ~ * 95 + 5 ] ; random between 5-100

i1 +
. [ 8 / 2 * 3 ] ; 12
i1 +
. [ 4 + 3 - 2 + 1 ] ; 6
i1 +
. [ 4 + 3 * 2 + 1 ] ; 11
i1 +
. [ (4 + 3)*(2 + 1)] ; 21

i1 +
. [ 2 * 2 & 3 ] ; 4
i1 +
. [ 3 & 2 * 2 ] ; 0
i1 +
. [ 4 | 3 * 3 ] ; 13
```

## The @ operator

New in Csound version 3.56 are  $@x$  (next power-of-two greater than or equal to  $x$ ) and  $@@x$  (next power-of-two-plus-one greater than or equal to  $x$ ).

```
[ @ 11 ] will evaluate to 16
[ @@ 11 ] to 17
```

## Strings in p-fields

You can pass a string as a p-field instead of a number, like this:

```
i 1 0 10 "A4"
```

The string can be received by the instrument and further processed using the *string opcodes*.

### Note

Currently only one p-field can contain a string (i.e. no more than one string per line is al-

lowed). You can overcome this using *strset* and *strget*.

---

# Front Ends

Front ends are programs that provide some form of user interface for Csound. Within these programs, Csound is used to generate sound, and familiarity with Csound code is required in order to use them. Front ends typically add helpful features, such as syntax coloring, graphic widgets, or tools for algorithmic score generation, that are not part of Csound itself. Most of these programs were created by a single person, so some of them are not being maintained. Below is a list (certainly not complete, and perhaps not up to date) of front ends available for Csound.

Most often, you'll want to download and install Csound itself before downloading and installing a front end. Some front ends require particular versions of Csound, so if you plan to use a front end, it's recommended that you verify its compatibility before installing Csound.

## CsoundQt

CsoundQt is a versatile, cross-platform GUI (graphical user interface) which is bundled with the standard Csound distribution. Created and maintained by Andres Cabrera, QuteCsound provides a multi-tabbed editor, graphic widgets for real-time sound control, and an opcode help system that links to this manual. At this writing (2013) CsoundQt is in active development, so the version installed in your system when you install Csound may not be the most current. The most recent version can be found at <http://qutecsound.sourceforge.net/>.

## Blue

A cross-platform composition-oriented front end written by Steven Yi in Java. The user interface provides a timeline structured somewhat like a digital multitrack, but differs in that timelines can be embedded within timelines (polyObjects). This allows for a compositional organization in time that many users will find intuitive, informative, and flexible. Each instrument and score section in a Blue project has its own editing window, which makes organizing large projects easier. Blue can be downloaded at Blue Home Page [<http://csounds.com/stevenyi/blue/>].

## Cabbage

Cabbage is a Csound frontend that provides users with the means to develop audio plugins and standalone software across the three major operating systems. While Cabbage makes use of underlying plugin technologies such as Steinberg's VST SDK, ASIO, etc, Csound is used to process all incoming and outgoing audio. Cabbage also provides a growing collection of GUI widgets ranging from simple sliders to automatable XY-pads. All GUI widgets in a Cabbage plugin can be controlled via host automation in a plugin host, thereby providing a quick and effective means of automating Csound instrument parameters in both commercial and non-commercial DAWs. Cabbage can be downloaded at Cabbage Home Page [<https://github.com/cabbageaudio/cabbage/releases>].

## WinXound

WinXound is a free and open-source Front-End GUI Editor with syntax highlighting for CSound 6, CSoundAV, CSoundAC, with Python and Lua support, developed by Stefano Bonetti. It runs on Microsoft Windows, Apple Mac OsX and Linux. You can get it at the WinXound Front Page [<http://winxound.codeplex.com/>].

## Winsound

Winsound was formerly part of the main Csound tree. It is now available only as source code. Winsound is a cross-platform FLTK port of Barry Vercoe's original front-end for csound. Some partially sighted or unsighted users report success using Winsound with text-to-speech software.

## CsoundAC

### Python Scripting

You can use CsoundAC as a Python extension module. You can do this in a standard Python interpreter, such as Python command line or the Idle Python GUI.

To use CsoundAC in a standard Python interpreter, import CsoundAC.

```
import CsoundAC
```

The CsoundAC module automatically creates an instance of CppSound named csound, which provides an object-oriented interface to the Csound API. In a standard Python interpreter, you can load a Csound .csd file and perform it like this:

```
C:\Documents and Settings\mkg>python
Python 2.3.3 (#51, Dec 18 2003, 20:22:39) [MSC v.1200 32 bit (Intel)] on win32
Type "help", "copyright", "credits" or "license" for more information.

The `koch.py` script shows how to use Python to do algorithmic composition for Csound. You can use Python triple-quoted string literals to hold your Csound files right in your script, and assign them to Csound:

```
csound.setOrchestra('''sr = 44100  
kr = 441  
ksmps = 100  
nchnls = 2  
Odbfs = .1  
instr 1,2,3,4,5 ; FluidSynth General MID

csound.setCommand("csound --opcode-lib=c:/projects/csound5/fluid.dll \  
-RWdfo ./koch.wav ./temp.orc ./temp.sco")  
csound.exportForPerformance()  
csound.perform()
```

## CsoundVST

CsoundVST is a multi-function front end for Csound, based on the Csound API. CsoundVST runs as a stand-alone graphical user interface to Csound, and it also runs as a VST instrument or effect plugin in

VST hosts such as Cubase with the same user interface. CsoundVST is part of the main csound source tree, but is not included in standard distributions, due to licensing limitations of Steinberg's VST SDK.

## Standalone

To run CsoundVST as a stand-alone front end to Csound, execute CsoundVST. When the program has loaded, you will see a graphical user interface with a row of buttons along the top. Click on the *Open...* button to load a *.csd* file. You can also click on the *Open...* button and load a *.orc* file, then click on the *Import...* button to add a *.sco* file. You can edit the Csound command, the orchestra file, or the score file in the respective tabs of the user interface. When all is satisfactory, click on the *Perform* button to run Csound. You can stop a performance at any time by clicking on the *Stop* button.

## VST Plugin

The following instructions are for Cubase 4.0. You would follow roughly similar procedures in other hosts.

Use the *Devices* menu, *Plug-In Information* dialog, *VST Plug-Ins* tab, *VST 2.x Plug-in Paths* dialog, *Add* button to add your *csound/bin* directory to Cubase's plugin path. You can have multiple directories separated by semicolons. Then select the CsoundVST path and click on the *Set as Shared Folder* button.

Quit Cubase, and start it again.

Use the *File* menu, *New Project* dialog to create a new song.

Use the *Project* menu, *Add Track* submenu, to add a new MIDI track.

Use the pencil tool to draw a *Part* on the track a few measures long. Write some music in the *Part* using the *Event* editor or the *Score* editor.

Use the *Devices* menu (or the F11 key) to open the *VST Instruments* dialog.

Click on one of the *No VST Instrument* labels, and select *CsoundVST* from the list that pops up.

Click on the *e* (for edit) button to open the *CsoundVST* dialog.

On the Settings page, check the *Instrument* box in the VST Plugin group, and the *Classic* box in the *Csound performance mode* group. Then click on the *Apply* button.

Click on the *Open* button to bring up the file selector dialog. Navigate to a directory containing a Csound csd file suitable for MIDI performance, such as *csound/examples/CsoundVST.csd*. Click on the *OK* button to load the file. You can also open and import a suitable *.orc* and *.sco* file as described above.

In any event, the command line in the *Classic Csound command line* text box must specify *-+rtmidi=null -M0*, and should read something like this:

```
csound -f -h -+rtmidi=null -M0 -d -n -m7 --midi-key-oct=4 --midi-velocity=5 temp.orc temp.sco
```

Click on the *VST Instruments* dialog's on/off button to turn it on. This should compile the Csound orchestra.

In the *Cubase Track Inspector*, click on the *out: Not Assigned* label and select *CsoundVST* from the list that pops up.

On the ruler at the top of the *Arrangement* window, select the loop end point and drag it to the end of your part, then click on the loop button to enable looping.

Click on the *play* button on the *Transport* bar. You should hear your music played by CsoundVST.

Try assigning your track to different channels; a different Csound instrument will perform each channel.

When you save your song, your Csound orchestra will be saved as part of the song and re-loaded when you re-load the song.

You can click on the *Orchestra* tab and edit your Csound instruments while CsoundVST is playing. To hear your changes, just click on the CsoundVST *Perform* button to recompile the orchestra.

You can assign up to 16 channels to a single CsoundVST plugin.

---

# Building Csound

Csound has become a complex project and can involve many dependencies. Unless you are a Csound developer or need to develop Csound plugins, you should try to use one of the pre-compiled distributions from <http://www.sourceforge.net/projects/csound>.

Detailed and up to date information about building Csound from source can be found in the BUILD.md [https://github.com/csound/csound/blob/develop/BUILD.md] file in the Csound6 sources.

---

# Csound Links

Csound's "home page" can be found at <http://csound.github.io>.

Another Csound page, maintained by Richard Boulanger, can be found at <http://csounds.com>.

The Csound source code is maintained by John ffitch and others at <http://www.sourceforge.net/projects/csound>. The most recent versions and precompiled packages for most platforms also can be downloaded here [[http://sourceforge.net/project/showfiles.php?group\\_id=81968](http://sourceforge.net/project/showfiles.php?group_id=81968)].

A Csound mailing list exists to discuss Csound. It is run by John ffitch of Bath University, UK. To have your name put on the mailing list send an empty message to: [csound-subscribe@lists.bath.ac.uk](mailto:csound-subscribe@lists.bath.ac.uk) [<mailto:csound-subscribe@lists.bath.ac.uk>]. You can also subscribe to the digest (1 message per day) by sending an empty email to: [csound-digest-subscribe@lists.bath.ac.uk](mailto:csound-digest-subscribe@lists.bath.ac.uk) [<mailto:csound-digest-subscribe@lists.bath.ac.uk>]. Posts sent to [csound@lists.bath.ac.uk](mailto:csound@lists.bath.ac.uk) [<mailto:csound@lists.bath.ac.uk>] go to all subscribed members of the list. You can browse the csound mailing list archives here [[http://agentcities.cs.bath.ac.uk/%7ebwillkie/list\\_arch.php](http://agentcities.cs.bath.ac.uk/%7ebwillkie/list_arch.php)]

Similarly, the `csound-devel` mailing list exists to discuss Csound development. For more information on this list, go to <http://lists.sourceforge.net/lists/listinfo/csound-devel>. Posts sent to [csound-devel@lists.sourceforge.net](mailto:csound-devel@lists.sourceforge.net) [<mailto:csound-devel@lists.sourceforge.net>] go to all subscribed members of the list.

# Signal Generators

## Additive Synthesis/Resynthesis

The opcodes for additive synthesis and resynthesis are:

- *adsyn*
- *adsynt*
- *adsynt2*
- *hsboscil*

See the section *Spectral processing* for more information and further additive/resynthesis opcodes.

## Basic Oscillators

The basic oscillator opcodes are: (note that opcodes that end with '1' implement linear interpolation and those that end with '3' implement cubic interpolation)

- Oscillator Banks: *oscblk*
- Simple table oscillators: *oscil*, *oscil3* and *oscili*.
- Simple, fast sine oscillator: *oscils*
- Precision oscillators: *poscil* and *poscil3*.
- More flexible oscillators: *oscilikt*, *osciliktp*, *oscilikts* and *osciln* (also called *oscilx*).

Oscillators can also be constructed from generic table read opcodes. See the *Table Read/Write operations* section.

## LFOs

- *lfo*
- *vibr*
- *vibrato*

See the section *Table access* for other table reading opcodes that can be used as oscillators. Also see the section *Dynamic spectrum Oscillators*.

## Dynamic Spectrum Oscillators

The opcodes that generate dynamic spectra are:

- Harmonic spectra: *buzz* and *gbuzz*
- Impulse generator: *mpulse*
- Band limited oscillators (analog modelled): *vco* and *vco2*

The following opcodes can be used to generate band-limited waveforms for use with *vco2* and other oscillators:

- *vco2init*
- *vco2ft*
- *vco2ift*

## FM Synthesis

The FM synthesis opcodes are:

- *foscil*
- *foscili*
- *crossfm*, *crossfmi*, *crosspm*, *crosspmi*, *crossfppm*, and *crossfppmi*.

## FM instrument models

- *fmb3*
- *fmbell*
- *fmmetal*
- *fmpercfl*
- *fmrhode*
- *fmvoice*
- *fmwurlie*

## Granular Synthesis

The granular synthesis opcodes are:

- *diskgrain*
- *fof*

- *fof2*
- *fog*
- *grain*
- *grain2*
- *grain3*
- *granule*
- *partikkel*
- *partikkelsync*
- *sdwarp*
- *sdwarpst*
- *syncgrain*
- *syncloop*
- *vosim*

## Hyper Vectorial Synthesis

- *vphaseseg*
- *hvs1*
- *hvs2*
- *hvs3*

## Linear and Exponential Generators

The opcodes that generate linear or exponential curves or segments are:

- *expon*
- *expcurve*
- *expseg*
- *expsega*
- *expsegr*

- *gainslider*
- *jspline*
- *line*
- *linseg*
- *linsegr*
- *logcurve*
- *loopseg*
- *loopsegp*
- *lpshold*
- *lpsholdp*
- *rspline*
- *scale*
- *transeg*

## Envelope Generators

The following envelope generators are available:

- *adsr*
- *madsr*
- *mxadsr*
- *xadsr*
- *linen*
- *linenr*
- *envlpx*
- *envlpxr*

Consult the *Linear and exponential generators* section for additional methods to create envelopes.

## Models and Emulations

The following opcodes model or emulate the sounds of other instruments (some based on the STK toolkit by Perry Cook):

- *bamboo*

- *barmodel*
- *cabasa*
- *crunch*
- *dripwater*
- *gogobel*
- *guiro*
- *mandol*
- *marimba*
- *moog*
- *sandpaper*
- *sekere*
- *shaker*
- *sleighbells*
- *stix*
- *tambourine*
- *vibes*
- *voice*

Also, see the *STK Opcodes* section for information on the STK opcodes.

Other models and emulations

- *lorenz*
- *planet*
- *prepiano*
- Fractal Number (Mandelbrot set) generator: *mandel*
- *chuap*
- *gendy*
- *gendyc*
- *gendyx*

A section on physical modeling using the waveguide principles can be found here: *Waveguide Physical Modeling*

## Phasors

---

The opcodes that generate a moving phase value:

- *phasor*
- *phasor*
- *phasorbnk*
- *syncphasor*

These opcodes are useful in combination with the *Table access* opcodes.

## Random (Noise) Generators

Opcodes that generate random numbers are:

- *betarnd*
- *bexprnd*
- *cauchy*
- *cuserrnd*
- *duserrnd*
- *dust*
- *dust2*
- *exprand*
- *fractalnoise*
- *gauss*
- *gausstrig*
- *linrand*
- *noise*
- *pcauchy*
- *pinkish*
- *pinker*
- *poisson*
- *rand*
- *randh*
- *randi*

- *rnd31*
- *random*
- *randomh*
- *randomi*
- *trirand*
- *unirand*
- *urd*
- *weibull*
- *jitter*
- *jitter2*
- *trandom*

See *seed* which sets the global seed value for all x-class noise generators, as well as other opcodes that use a random call, such as *grain*. *rand*, *randh*, *randi*, *rnd(x)* and *birnd(x)* are not affected by *seed*.

See also functions which generate random numbers in the section *Random Functions*.

## Sample Playback

Opcodes that implement sample playback and looping are:

- *bbcutm*
- *bbcuts*
- *flooper*
- *flooper2*
- *loscil*
- *loscil3*
- *loscilx*
- *lphasor*
- *lposcil*
- *lposcil3*
- *lposcila*
- *lposcilsa*
- *lposcilsa2*

- *sndloop*
- *waveset*

See also the *Signal Input* section for other ways to input sound.

## Soundfonts

### Fluid Opcodes

The fluid family of opcodes wraps Peter Hannape's SoundFont 2 player, FluidSynth: *fluidEngine* for instantiating a FluidSynth engine, *fluidSetInterpMethod* for setting interpolation method for a channel in a FluidSynth engine, *fluidLoad* for loading SoundFonts, *fluidProgramSelect* for assigning presets from a SoundFont to a FluidSynth engine's MIDI channel, *fluidNote* for playing a note on a FluidSynth engine's MIDI channel, *fluidCCi* for sending a controller message at i-time to a FluidSynth engine's MIDI channel, *fluidCCK* for sending a controller message at k-rate to a FluidSynth engine's MIDI channel, *fluidControl* for playing and controlling loaded Soundfonts (using 'raw' MIDI messages), *fluidOut* for receiving audio from a single FluidSynth engine, and *fluidAllOut* for receiving audio from all FluidSynth engines.

- *fluidAllOut*
- *fluidCCi*
- *fluidCCK*
- *fluidControl*
- *fluidEngine*
- *fluidLoad*
- *fluidNote*
- *fluidOut*
- *fluidProgramSelect*
- *fluidSetInterpMethod*

### "Old" Soundfont opcodes

These opcodes can also use soundfonts to generate sound. *sfplay* etc. were created for one purpose -- to use the samples in SoundFonts. The fluid opcodes were created for another purpose -- to use SoundFonts more or less the way they were designed to be used, i.e. using keyboard mappings, layers, internal processing, etc.

- *sfilist*
- *sfinstr*
- *sfinstr3*
- *sfinstr3m*

- *sfinstrm*
- *sfloat*
- *sfpassign*
- *splay*
- *splay3*
- *splay3m*
- *splaym*
- *sflooper*
- *sfplist*
- *sfpreset*

## Scanned Synthesis

Scanned synthesis is a variant of physical modeling, where a network of masses connected by springs is used to generate a dynamic waveform. The opcode *scnu* defines the mass/spring network and sets it in motion. The opcode *scans* follows a predefined path (trajectory) around the network and outputs the detected waveform. Several *scans* instances may follow different paths around the same network.

These are highly efficient mechanical modelling algorithms for both synthesis and sonic animation via algorithmic processing. They should run in real-time. Thus, the output is useful either directly as audio, or as controller values for other parameters.

The Csound implementation adds support for a scanning path or matrix. Essentially, this offers the possibility of reconnecting the masses in different orders, causing the signal to propagate quite differently. They do not necessarily need to be connected to their direct neighbors. Essentially, the matrix has the effect of “molding” this surface into a radically different shape.

To produce the matrices, the table format is straightforward. For example, for 4 masses we have the following grid describing the possible connections:

|   | 1 | 2 | 3 | 4 |
|---|---|---|---|---|
| 1 |   |   |   |   |
| 2 |   |   |   |   |
| 3 |   |   |   |   |
| 4 |   |   |   |   |

Whenever two masses are connected, the point they define is 1. If two masses are not connected, then the point they define is 0. For example, a unidirectional string has the following connections: (1,2), (2,3), (3,4). If it is bidirectional, it also has (2,1), (3,2), (4,3)). For the unidirectional string, the matrix appears:

|   | 1 | 2 | 3 | 4 |
|---|---|---|---|---|
| 1 | 0 | 1 | 0 | 0 |
| 2 | 0 | 0 | 1 | 0 |

|   |   |   |   |   |
|---|---|---|---|---|
| 3 | 0 | 0 | 0 | 1 |
| 4 | 0 | 0 | 0 | 0 |

The above table format of the connection matrix is for conceptual convenience only. The actual values shown in the table are obtained by *scans* from an ASCII file using *GEN23*. The actual ASCII file is created from the table model row by row. Therefore the ASCII file for the example table shown above becomes:

0100001000010000

This matrix example is very small and simple. In practice, most scanned synthesis instruments will use many more masses than four, so their matrices will be much larger and more complex. See the example in the *scans* documentation.

Please note that the generated dynamic wavetables are very unstable. Certain values for masses, centering, and damping can cause the system to “blow up” and the most interesting sounds to emerge from your loudspeakers!

The supplement to this manual contains a tutorial on scanned synthesis. The tutorial, examples, and other information on scanned synthesis is available from the Scanned Synthesis page at cSounds.com.

Scanned synthesis developed by Bill Verplank, Max Mathews and Rob Shaw at Interval Research between 1998 and 2000.

Opcodes that implement scanned synthesis are:

- *scanhammer*
- *scans*
- *scantable*
- *scanu*
- *xscanmap*
- *xscans*
- *xscansmap*
- *xscanu*

## Table Access

The opcodes that access tables are:

- *oscil1*
- *oscill1i*
- *osciln*

- *oscilx*
- *table*
- *table3*
- *tablei*

Opcodes ending in 'i' implement linear interpolation and opcodes ending in '3' implement cubic interpolation.

The following opcodes implement fast table reading/writing without boundary checks:

- *tab*
- *tab\_i*
- *tabw*
- *tabw\_i*

See the sections *Table Queries*, *Read/Write Operations* and *Table Reading with Dynamic Selection* for other table operations.

### Note

Although tables with a size which is not a power of two can be created using a negative size (see *fscore statement*), some opcodes will not accept them.

## Wave Terrain Synthesis

The opcode that uses wave terrain synthesis is *wterrain*.

## Waveguide Physical Modeling

The opcodes that implement waveguide physical modeling are:

- *pluck*
- *repluck*
- *wgbow*
- *wgbowedbar*
- *wgbrass*
- *wgclar*
- *wgflute*
- *wgpluck*

- *wgpluck2*
- *wguide1*
- *wguide2*

---

# Signal Input and Output

## File Input and Output

The opcodes for file input and output are:

- File open/close: *fopen* and *fclose*.
- File output: *dumpk*, *dumpk2*, *dumpk3*, *dumpk4*, *fout*, *fouti*, *foutir*, *foutk* and *hdf5write*
- File input: *readk*, *readk2*, *readk3*, *readk4*, *fin*, *fini* and *fink*
- Utilities for use with the fout opcodes: *clear*, *vincr*
- Printing to a file: *fprints* and *fprintks*

## Signal Input

The opcodes that receive audio signals are:

- Synchronous input: *in*, *in32*, *inch*, *inh*, *ino*, *inq*, *inrg*, *ins* and *inx*
- File streaming: *diskin*, *diskin2*, *soundin* and *hdf5read*
- User defined channel input: *invalue*
- Streaming input: *soundin*
- Websocket input: *websocket*
- Direct to zak input: *inz*

See the section *Software Bus* for input and output through the API.

The *mp3in* allows reading of mp3 files, which are currently not supported by ordinary reading methods inside Csound.

## Signal Output

The opcodes that write audio signals are:

- Synchronous output: *out*, *out32*, *outc*, *outch*, *outh*, *outo*, *outrg*, *outq*, *outq1*, *outq2*, *outq3*, *outq4*, *outs*, *outs1*, *outs2*, *outx* and *hdf5write*
- Streaming output: *soundout* and *soundouts*
- User defined channel output: *outvalue*
- Direct from zak output: *outz*

- Websocket output: *websocket*

The opcode *monitor* can be used for monitoring the complete output of csound (the output spout frame).

See the section *Software Bus* for input and output through the API.

## Software Bus

Csound implements a software bus for internal routing or routing to external software calling the Csound API.

The opcodes to use the software bus are:

- *chn\_k*
- *chn\_a*
- *chn\_S*
- *chnclear*
- *chnexport*
- *chnmix*
- *chnparams*

## Printing and Display

Opcodes for printing and displaying values are:

- *dispfft*
- *display*
- *flashtxt*
- *print*
- *printf*
- *printf\_i*
- *printk*
- *printk2*
- *printks*
- *prints*

## Sound File Queries

The opcodes that query information about files are:

- *filelen*
- *filenchnl*
- *filepeak*
- *filesr*
- *filevalid*

---

# Signal Modifiers

## Amplitude Modifiers and Dynamic processing

The opcodes that modify amplitude are:

- *balance*
- *compress*
- *clip*
- *dam*
- *gain*

The opcode *0dbfs* facilitates the use of amplitude by removing the need to use of explicit sample values.

## Convolution and Morphing

The opcodes that convolve and morph signals are:

- *convolve* also called *convle*
- *cross2*
- *dconv*
- *ftconv*
- *fimorf*
- *pconvolve*

## Delay

### Fixed delays

- *delay*
- *delay1*
- *delayk*

## Delay Lines

- *delayr*
- *delayw*
- *deltap*
- *deltap3*
- *deltapi*
- *deltapn*
- *deltapx*
- *deltapxw*

## Variable delays

- *vdelay*
- *vdelay3*
- *vdelayx*
- *vdelayxs*
- *vdelayxq*
- *vdelayxw*
- *vdelayxwq*
- *vdelayxws*

## Multitap delays

- *multitap*

## Panning and Spatialization

### Amplitude spatialization

- *locsend*
- *locsig*
- *pan*

- *pan2*
- *space*
- *spdist*
- *spsend*

## 3D spatialization with simulation of room acoustics

- *spat3d*
- *spat3di*
- *spat3dt*

## Vector Base Amplitude Panning

- *vbap16*
- *vbap16move*
- *vbap4*
- *vbap4move*
- *vbap8*
- *vbap8move*
- *vbaplsinit*
- *vbapz*
- *vbapzmove*

## Binaural spatialization

- *hrtfer*
- *hrtfmove*
- *hrtfmove2*
- *hrtfstat*

## Ambisonics

- *bformdec*

- *bformenc*

## Reverberation

The opcodes one can use for reverberation are:

- *alpass*
- *babo*
- *comb*
- *freeverb*
- *nestedap*
- *nreverb* (also called *reverb2*)
- *reverb*
- *reverbsc*
- *valpass*
- *vcomb*

## Sample Level Operators

The opcodes one may use to modify signals are:

- *a(k)*
- *denorm*
- *diff*
- *downsamp*
- *fold*
- *i(k)*
- *integ*
- *interp*
- *k(i)*
- *ntrpol*
- *samphold*
- *upsamp*

- *vaget*
- *vaset*

## Signal Limiters

Opcodes that can be used to limit signals are:

- *limit*
- *mirror*
- *wrap*

## Special Effects

Opcodes that generate special effects are:

- *distort*
- *distort1*
- *exciter*
- *flanger*
- *harmon*
- *phaser1*
- *phaser2*

## Standard Filters

### Resonant Low-pass filters

- *areson*
- *lowpass2*
- *lowres*
- *lowresx*
- *lpf18*
- *moogvcf*
- *moogladder*

- *reson*
- *resonr*
- *resonx*
- *resony*
- *resonz*
- *rezzy*
- *statevar*
- *svfilter*
- *tbvcf*
- *vlowres*
- *bqrez*

## Standard filters

- Hi-pass filters: *atone*, *atonex*
- Low-pass filters: *tone*, *tonex*
- Biquad filters: *biquad* and *biquada*.
- Butterworth filters: *butterbp*, *butterbr*, *butterhp*, *butterlp* (which are also called *butbp*, *butbr*, *buthp*, *butlp*)
- General filters: *cfilt*

## Control signal filters

- *aresonk*
- *atonek*
- *lineto*
- *port*
- *portk*
- *resonk*
- *resonxk*
- *tlineto*
- *tonek*

# Specialized Filters

## High pass filters

- *dcblock*
- *dcblock2*

## Parametric EQ

- *pareq*
- *rbjeq*
- *eqfil*

## Other filters

- *nlfilt*
- *filter2*
- *fofilter*
- *hilbert*
- *mode*
- *zfilter2*

# Waveguides

The opcodes that use waveguides to modify a signal are:

- *streson*
- *wguide1*
- *wguide2*

# Waveshaping and Phase Distortion

These opcodes can perform dynamic waveshaping or phaseshaping (a.k.a. phase distortion). They differ from traditional table-based methods of waveshaping by directly calculating the transfer function with one or more variable parameters for affecting the amount or results of the shaping. Most of these opcodes could be used on either an audio signal (for waveshaping) or a phasor (for phaseshaping) but tend to work best for one of these applications.

These opcodes are good for waveshaping:

- *chebyshevpoly*
- *clip*
- *distort*
- *distort1*
- *polynomial*
- *powershape*

These opcodes are good for phaseshaping:

- *pdclip*
- *pdhalf*
- *pdhalfy*

---

# Instrument Control

## Clock Control

The opcodes to start and stop internal clocks are:

- *clockoff*
- *clockon*

These clocks count CPU time. There are 32 independent clocks available. You can use the opcode *readclock* to read current values of a clock. See *Time Reading* for other timing opcodes.

## Conditional Values

The opcodes for conditional values are ==, >=, >, <, <=, and !=.

## Duration Control Statements

The opcodes one can use to manipulate a note's duration are:

- *ihold*
- *turnoff*
- *turnoff2*
- *turmon*

For other realtime instrument control see *Real-time Performance Control* and *Instrument Invocation*.

## FLTK Widgets and GUI controllers

Widgets allow the design of a custom Graphical User Interface (GUI) to control an orchestra in real-time. They are derived from the open-source library FLTK (Fast Light Tool Kit). This library is one of the fastest graphic libraries available, supports OpenGL and should be source compatible with different platforms (Windows, Linux, Unix and Mac OS). The subset of FLTK implemented in Csound provides the following types of objects:

### Containers

*FLTK Containers* are widgets that contain other widgets such as panels, windows, etc. Csound provides the following container objects:

- Panels
- Scroll areas
- Pack

|               |  |
|---------------|--|
|               | <ul style="list-style-type: none"><li>• Tabs</li><li>• Groups</li></ul>  |
| Valuators     | The most useful objects are named <i>FLTK Valuators</i> . These objects allow the user to vary synthesis parameter values in real-time. Csound provides the following valuator objects: <ul style="list-style-type: none"><li>• Sliders</li><li>• Knobs</li><li>• Rollers</li><li>• Text fields</li><li>• Joysticks</li><li>• Counters</li></ul> |
| Other widgets | There are <i>other FLTK widgets</i> that are not valuators nor containers: <ul style="list-style-type: none"><li>• Buttons</li><li>• Button banks</li><li>• Labels</li><li>• Keyboard and Mouse sensing</li></ul>  |

Also there are some other opcodes useful to modify the *widget appearance*:

- Updating widget value.
- Setting primary and selection colors of a widget.
- Setting font type, size and color of widgets.
- Resizing a widget.
- Hiding and showing a widget.

There are also these *general opcodes* that allow the following actions:

- Running the widget thread: *FLrun*
- Loading snapshots containing the status of all valuators of an orchestra: *FLgetsnap* and *FLloadsnap*.
- Saving snapshots containing the status of all valuators of an orchestra: *FLsavesnap* and *FLsetsnap*
- Setting the snapshot group of a declared valuator: *FLsetSnapGroup*

Below is a simple example of Csound code to create a window. Notice that all opcodes are init-rate and must be called only once per session. The best way to use them is to place them in the header section of

an orchestra, before any instrument. Even though placing them inside an instrument is not prohibited, unpredictable results can occur if that instrument is called more than once.

Each container is made up of a couple of opcodes: the first indicating the start of the container block and the last indicating the end of that container block. Some container blocks can be nested but they must not be crossed. After defining all containers, a widget thread must be run by using the special FLrun opcode that takes no arguments.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out    Audio in     No messages
-odac          -iadc      -d      ;;;RT audio I/O
; For Non-realtime output leave only the line below:
; -o linseg.wav -W ;; for file output any platform
</CsOptions>
<CsInstruments>
;*****
sr=48000
kr=480
ksmps=100
nchnls=1

;*** It is recommended to put almost all GUI code in the
;*** header section of an orchestra

        FLpanel      "Panel1", 450,550 ;***** start of container
; some widgets should contained here
        FLpanelEnd   ;***** end of container

        FLrun        ;***** runs the widget thread, it is always required!
instr 1
;put some synthesis code here
endin
;*****
</CsInstruments>
<CsScore>
f 0 3600 ;dummy table for realtime input
e

</CsScore>
</CsoundSynthesizer>
```

The previous code simply creates a panel (an empty window because no widgets are defined inside the container).

The following example creates two panels and inserts a slider inside each of them:

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out    Audio in     No messages
-odac          -iadc      -d      ;;;RT audio I/O
; For Non-realtime output leave only the line below:
; -o linseg.wav -W ;; for file output any platform
</CsOptions>
<CsInstruments>
;*****
sr=48000
kr=480
ksmps=100
nchnls=1

        FLpanel      "Panel1", 450,550,100,100 ;***** start of container
gk1,ih1  FLslider   "FLslider 1", 500, 1000, 0 ,1, -1, 300,15, 20,50
        FLpanelEnd   ;***** end of container

        FLpanel      "Panel2", 450,550,100,100 ;***** start of container
gk2,ih2  FLslider   "FLslider 2", 100, 200, 0 ,1, -1, 300,15, 20,50
```

```
FLpanelEnd      ;***** end of container
FLrun          ;***** runs the widget thread, it is always required!

instr 1
; gk1 and gk2 variables that contain the output of valuator
; widgets previously defined, can be used inside any instrument
printk2 gk1
printk2 gk2  ;print the values of the valuators whenever they change
endin
;*****
</CsInstruments>
<CsScore>
f 0 3600 ;dummy table for realtime input
e

</CsScore>
</CsoundSynthesizer>
```

All widget opcodes are init-rate opcodes, even if valuators output k-rate variables. This happens because an independent thread is run based on a callback mechanism. It consumes very few processing resources since there is no need of polling. (This differs from other MIDI based controller opcodes.) So you can use any number of windows and valuators without degrading the real-time performance.

## FLTK Containers

The opcodes for FLTK containers are:

- *FLgroup*
- *FLgroupEnd*
- *FLpack*
- *FLpackEnd*
- *FLpanel*
- *FLpanelEnd*
- *FLscroll*
- *FLscrollEnd*
- *FLtabs*
- *FLtabsEnd*

## FLTK Valuators

The opcodes for FLTK valuators are:

- *FLcount*
- *FLjoy*
- *FLknob*

- *FLroller*
- *FLslider*
- *FLtext*

## Other FLTK Widgets

Other FLTK widget opcodes are:

- *FLbox*
- *FLbutBank*
- *FLbutton*
- *FLexecButton*
- *FLkeyIn*
- *FLhvsBox*
- *FLhvsBoxSetValue*
- *FLmouse*
- *FLprintk*
- *FLprintk2*
- *FLslidBnk*
- *FLslidBnk2*
- *FLslidBnkGetHandle*
- *FLslidBnkSet*
- *FLslidBnk2Set*
- *FLslidBnk2Setk*
- *FLvalue*
- *FLvkeybd*
- *FLvslidBnk*
- *FLvslidBnk2*
- *FLxyin*

## Modifying FLTK Widget Appearance

The following opcodes modify FLTK widget appearance:

- *FLcolor*
- *FLcolor2*
- *FLhide*
- *FLlabel*
- *FLsetAlign*
- *FLsetBox*
- *FLsetColor*
- *FLsetColor2*
- *FLsetFont*
- *FLsetPosition*
- *FLsetSize*
- *FLsetText*
- *FLsetTextColor*
- *FLsetTextSize*
- *FLsetTextType*
- *FLsetVal\_i*
- *FLsetVal*
- *FLshow*

## General FLTK Widget-related Opcodes

The general FLTK widget-related opcodes are:

- *FLgetsnap*
- *FLloadsnap*
- *FLrun*
- *FLsavesnap*
- *FLsetsnap*
- *FLupdate*
- *FLsetSnapGroup*

## Instrument Invocation

---

The opcodes one can use to create score events from within a orchestra are:

- *event*
- *event\_i*
- *scoreline\_i*
- *scoreline*
- *schedule*
- *schedwhen*
- *schedkwhen*
- *schedkwhennamed*

The *mute* opcode can be used to mute/unmute instruments during a performance.

Instruments definitions can be removed using the *remove* opcode.

## Program Flow Control

The opcodes to manipulate which orchestra statements are executed are:

- *cgoto*
- *cigoto*
- *ckgoto*
- *engoto*
- *elseif*
- *else*
- *endif*
- *goto*
- *if*
- *igoto*
- *kgoto*
- *tigoto*
- *timeout*

Opcodes to create looping constructions are:

- *loop\_ge*
- *loop\_gt*
- *loop\_le*
- *loop\_lt*
- *until*
- *while*

## Warning

Some of these opcodes work at i-rate even if they contain k- or a- rate comparisons. See the *Reinitialization* section.

# Real-time Performance Control

Opcodes that monitor and control real-time performance are:

- *active*
- *cpuprc*
- *maxalloc*
- *prealloc*
- *jacktransport*

The running csound process can be terminated using *exitnow*.

# Initialization and Reinitialization

Opcodes used for the initialization of variables:

- *init*
- *tival*
- *=*
- *passign*
- *pset*

The opcodes that can generate another initialization pass are:

- *reinit*

- *rigoto*
- *rireturn*

The opcode *p* can be used to find score p-fields at i- or k-rate.

*nstrnum* returns the instrument number for a named instrument.

### Note

Note that a instrument may modify the p3 (duration) parameter at initialisation time. For example statements like

```
iattack = 0.02  
irelease = 0.04  
isustain = p3  
p3 = iattack + isustain + irelease
```

are valid.

## Sensing and Control

### TCL/TK widgets

- *button*
- *checkbox*
- *control*
- *setctrl*

## Keyboard and mouse sensing

- *sensekey* (also called *sense*)
- *xyin*

## Envelope followers

- *follow*
- *follow2*
- *peak*
- *rms*

## Tempo and Pitch estimation

- *ptrack*
- *pitch*
- *pitchamdf*
- *tempest*

## Tempo and Sequencing

- *tempo*
- *miditempo*
- *tempoval*
- *seqtime*
- *seqtime2*
- *trigger*
- *trigseq*
- *timedseq*
- *changed*

## System

- *getcfg*

## Score control

- *rewindscore*
- *setscorepos*

## Stacks

Csound implements a global stack that can be accessed with the following opcodes:

- *stack*
- *pop*
- *push*
- *pop\_f*
- *push\_f*

## Sub-instrument Control

These opcodes let one define and use a sub-instrument:

- *subinstr*
- *subinstrinit*

See also the UDO and *Orchestra Macros* Macros section for similar functionality.

## Time Reading

Opcodes one can use to read time values are:

- *readclock*
- *rtclock*
- *timeinstk*
- *timeinsts*
- *times*
- *timek*

You can obtain the system date using:

- *date* - Returns the number seconds since 1 January 1970.
- *dates* - Returns as a string the date and time specified.

You can also set up counters using *clockoff* and *clockon*.

---

# Function Table Control

Refer to the *f score statement*, *ftgen*, *ftgentmp*, *ftgenonce* and the *GEN Routines* section for information on creating tables.

Tables can be removed from memory using the *ffree* opcode.

Tables by default, require a size which is a power of two. However tables with any size can be generated by specifying the size as a negative number (see *f score statement*).

## Note

Not all opcodes accept tables whose size is not a power of two, as this may be a requirement for internal processing.

For information on table access, consult the section *Table Access*.

Tables for use with the *loscilx* opcode can be loaded using *sndload*.

## Table Queries

Opcodes the query tables for information are:

- For tables loaded from a sound file (using *GEN01*): *ftchnls*, *ftcps*, *ftlen*, *ftlptim* and *fts*
- For any table: *nsamp*, *ftlen*, *tableng*

The opcode *tabsum* calculates the sum of values in a table.

## Read/Write Operations

Opcodes that read and write to a table are:

- *ftloadk*
- *ftload*
- *ftsavek*
- *ftsave*
- *tablecopy*
- *tablegpw*
- *tableicopy*
- *tableigpw*
- *tableimix*
- *tableiw*

- *tablemix*
- *tablera*
- *tablew*
- *tablewa*
- *tablewkt*
- *tabmorph*
- *tabmorpha*
- *tabmorphak*
- *tabmorphi*
- *tabrec*
- *tabplay*
- *ftmorf*

Table values can be accessed within expressions using the *tb* family of opcodes.

Many oscillators are in fact specialized table readers. See the *Basic oscillators* section.

## Table Reading with Dynamic Selection

Opcodes that let one dynamically (at k-rate) select tables are:

- *tableikt*
- *tablekt*
- *tablexkt*

---

# Mathematical Operations

## Amplitude Converters

Opcodes to convert between different amplitude measurements are:

- *ampdb*
- *ampdbfs*
- *db*
- *dbamp*
- *dbfsamp*

Use *rms* to find the rms value of a signal. See also *0dbfs* for another way to handle amplitudes in csound.

## Arithmetic and Logic Operations

Opcodes that perform arithmetic and logic operations are `-`, `+`, `&&`, `//`, `*`, `/`, `^`, and `%`.

See the *Conditional Values* section and the *if* family of opcodes for usage of logical operators.

## Comparators and Accumulators

The following opcodes perform comparisons between signals at a-rate or k-rate, find maxima or minima, or accumulate the results of several computations or comparisons:

- *max*
- *max\_k*
- *maxabs*
- *maxabsaccum*
- *maxaccum*
- *min*
- *minabs*
- *minabsaccum*
- *minaccum*
- *vincr*
- *clear*

# Mathematical Functions

Opcodes that perform mathematical functions are:

- *abs*
- *ceil*
- *exp*
- *floor*
- *frac*
- *int*
- *log*
- *log10*
- *logbtwo*
- *pow*
- *powershape*
- *powoftwo*
- *round*
- *sqr $t$*

# Opcode Equivalents of Functions

Opcodes that perform the equivalent of mathematical functions are:

- *chebyshevpoly*
- *divz*
- *mac*
- *maca*
- *polynomial*
- *pow*
- *product*
- *sum*
- *taninv2*

## Random Functions

Opcodes that perform random functions are:

- *birnd*
- *rnd*

See the section *Random (Noise) Generators* for opcodes that generate random signals.

## Trigonometric Functions

Opcodes that perform trigonometric functions are:

- *cos*, *cosh* and *cosinv*
- *sin*, *sinh* and *sininv*
- *tan*, *tanh*, *taninv*, and *taninv2*.

# Linear Algebra Opcodes

Linear Algebra Opcodes — Scalar, vector, and matrix arithmetic on real and complex values.

## Description

These opcodes implement many linear algebra operations, from scalar, vector, and matrix arithmetic up to and including QR based eigenvalue decompositions. The opcodes are designed for digital signal processing, and of course other mathematical operations, in the Csound orchestra language.

The numerical implementation uses the gmm++ library from [home.gna.org/getfem/gmm\\_intro](http://home.gna.org/getfem/gmm_intro) [[http://home.gna.org/getfem/gmm\\_intro](http://home.gna.org/getfem/gmm_intro)].

### Warning

For applications with f-sig variables, array arithmetic must be performed only when the f-sig is "current," because f-rate is some fraction of k-rate; currency can be determined with the la\_k\_current\_f opcode.

For applications using assignments between real vectors and a-rate variables, array arithmetic must be performed only when the vectors are "current", because the size of the vector may be some integral multiple of ksmps; currency can be determined by means of the la\_k\_current\_vr opcode.

**Table 4. Linear Algebra Data Types**

| Mathematical Type | Code | Corresponding Csound Type or Types                |
|-------------------|------|---|
| real scalar       | r    | i-rate or k-rate variable                         |
| complex scalar    | c    | pair of i-rate or k-rate variables, e.g. "kr, ki" |
| real vector       | vr   | i-rate variable holding address of array          |
| real vector       | a    | a-rate variable                                   |
| real vector       | t    | function table number                             |
| complex vector    | vc   | i-rate variable holding address of array          |
| complex vector    | f    | fsig variable                                     |
| real matrix       | mr   | i-rate variable holding address of array          |
| complex matrix    | mc   | i-rate variable holding address of array          |

All arrays are 0-based; the first index iterates rows to give columns, the second index iterates columns to give elements.

All arrays are general and dense; banded, Hermitian, symmetric and sparse routines are not implemented.

An array can be of type code vr, vc, mr, or mc and is stored in an i-rate object. In orchestra code, an array is passed as a MYFLT i-rate variable that contains the address of the array object, which is actually stored in the allocator opcode instance. Although array variables are i-rate, of course their values and even shapes may change at i-rate or k-rate.

All operands must be pre-allocated; except for the creation opcodes, no opcode ever allocates any arrays. This is true even if the array appears on the left-hand side of an opcode! However, some operations may reshape arrays to hold results.

Arrays are automatically deallocated when their instrument is deallocated.

Not only for more efficient performance, but also to make it easier to remember opcode names, the performance rate, output value types, operation names, and input value types are deterministically encoded into the opcode name:

1. "la" for "linear algebra opcode family".
  2. "i" or "k" for performance rate.
  3. Type code(s) (see above table) for output value(s), but only if the type is not implicit from the input values.
  4. Operation name: common mathematical name (preferred) or abbreviation.
  5. Type code(s) for input values, if not implicit.

For additional details, see the gmm++ documentation at [ht-  
tp://download.gna.org/getfem/doc/gmmuser.pdf](http://download.gna.org/getfem/doc/gmmuser.pdf).

## Syntax

# Array Creation

ivr la i yr create irows

Create a real vector with `irows` rows

jvc la i vc create irows

Create a complex vector with irows rows

`imr` `la i mr create` `irows, icolumns [, odiagonall]`

Create a real matrix with `irows` rows and `icolumns` columns, with an optional value on the diagonal.

```
imc la i mc create irows, icolumns [., odiagonal r, odiagonal il]
```

Create a complex matrix with `irows` rows and `icolumns` columns, with an optional complex value on the diagonal.

## Array Introspection

irows la i size yr ivr

Return the number of rows in real vector jvr.

irows la\_i\_size\_vc ivc

Return the number of rows in complex vector ivc.

Return the number of rows and columns in real matrix imr.

Return the number of rows and columns in complex matrix `mat`.

BRITANNIA FIGHTS IN TANZANIA, THAT IS, IF THE VILLAGE ISN'T BEING WORN DOWN.

Return 1 if the real vector ivr is current, that is, if Csound's current audio sample frame stands at index 0 of the vector.

La Jolla Print Works

Print the value of real vector ivr

La Jolla Print Works

Print the value of complex vector jvc.

la i print mr imr

Print the value of real matrix jmr.

la i print mc imc

Print the value of complex matrix imc.

## Array Assignment and Conversion

ivr la\_i\_assign\_vr ivr

Assign the value of the real vector on the right-hand side to the real vector on the left-hand side, at i-rate.

ivr la\_k\_assign\_vr ivr

Assign the value of the real vector on the right-hand side to the

iyc la i assign vc iyc

ivc la\_k\_assign\_vc ivr

`imr` `la_i_assign_mr` `imr`

|     |                       |     |
|-----|-----------------------|-----|
| imc | <b>la_i_assign_mc</b> | imc |
| imc | <b>la_k_assign_mc</b> | imr |

## Warning

Assignments to vectors from tables or fsigs may resize the vectors.

Assignments to vectors from a-rate variables, or to a-rate variables from vectors, will be performed incrementally, one chunk of ksmps elements per kperiod. Therefore, array arithmetic on such vectors should only be performed when the vectors are current, as determined by the la\_k\_current\_vr opcode.

|           |                      |              |

# Array Opcodes

Array Opcodes

## Variable Name

An array must be created (via *init* or *fillarray*) as kMyName **plus** ending brackets. The brackets determine the dimensions of the array. So,

```
kArr[ ] init 10
```

creates a one-dimensional array of length 10, whereas

```
kArr[ ][ ] init 10, 10
```

creates a two-dimensional array with 10 rows and 10 columns.

After the initialization of the array, referring to the array as a whole is done **without** any brackets. Brackets are only used if an element is indexed:

```
kArr[ ] init 10          ;with brackets because of initialization  
kLen    = lenarray(kArr)  ;without brackets  
kFirstEl = kArr[0]        ;indexing with brackets
```

The same syntax is used for a simple copy via the '=' operator:

```
kArr1[ ] fillarray 1, 2, 3, 4, 5  
kArr2[ ] = kArr1           ;creates kArr2 as copy of kArr1
```

## k-rate

Note that most array operations are currently k-rate only. So like any other k-rate opcode, an operation on arrays will be automatically repeated every k-cycle. For instance, this code will repeat re-writing the array with different random values every k-cycle, as long as the instrument runs:

```
kArr[ ] init 10  
kIdx   = 0  
until kIdx == lenarray(kArr) do  
  kArr[kIdx] rnd31 10, 0  
  kIdx += 1  
od
```

If you want to avoid this, you must organize it in one of the usual ways, for instance by using a trigger:

```
kArr[] init 10
kTrig metro 1
if kTrig == 1 then ;do the following once a second
    kIndx = 0
    until kIndx == lenarray(kArr) do
        kArr[kIndx] rnd31 10, 0
        kIndx += 1
    od
endif
```

## Creation/Initialization

The usual way to create an array is with init:

```
kArr[] init 10      ;creates one-dimensional array with length 10
kArr[][] init 10, 10 ;creates two-dimensional array
```

A one-dimensional array can also be created and filled with distinct values by the opcode *fillarray*. This line creates a vector with length 4 and puts in the numbers [1, 2, 3, 4]:

```
kArr[] fillarray 1, 2, 3, 4
```

## Length

The function *lenarray(kArr)* reports the length of an array. See example for function *lenarray*.

## Copy Arrays to/from Tables

```
copyf2array kArr, kfn
```

copies data from an ftable to a vector.

```
copya2ftab kArr, kfn
```

copies data from a vector to an function table.

See examples for opcodes *copyf2array* and *copya2ftab*.

## Array Operations: Math

### +, -, \*, / on a Number

If the four basic math operators are used between an array and a scalar (number), the operation is applied to each element. The safest way to do this is to store the result in a new array:

```
kArr1[] fillarray 1, 2, 3  
kArr2[] = kArr1 + 10 ;(kArr2 is now [11, 12, 13])
```

Here is an example of array/scalar operations. It uses the file *array\_scalar\_math.csd* [examples/array\_scalar\_math.csd].

### Example 3. Example of array operations

```

## +, -, \*, / on a Second Array

If the four basic math operators are used between two arrays, the operation is applied element by element. The result can be straightforward stored in a new array:

```
kArr1[] fillarray 1, 2, 3
kArr2[] fillarray 10, 20, 30
kArr3[] = kArr1 + kArr2      ;(kArr3 is now [11, 22, 33])
```

Here is an example of array operations. It uses the file *array\_array\_math.csd* [examples/array\_array\_math.csd].

### Example 4. Example of array operations

```
<CsoundSynthesizer>
<CsOptions>
-n -m128
</CsOptions>
<CsInstruments>

instr 1

;create array and fill with numbers 1..10 resp .1..1
kArr1[] fillarray 1, 2, 3, 4, 5, 6, 7, 8, 9, 10
kArr2[] fillarray 1, 2, 3, 5, 8, 13, 21, 34, 55, 89

;print contents
    printf "%s", 1, "\nkArr1:\n"
kndx =
    0
    until kndx == lenarray(kArr1) do
        printf "kArr1[%d] = %f\n", kndx+1, kndx, kArr1[kndx]
    kndx +=
        1
    od
    printf "%s", 1, "\nkArr2:\n"
kndx =
    0
    until kndx == lenarray(kArr2) do
        printf "kArr2[%d] = %f\n", kndx+1, kndx, kArr2[kndx]
    kndx +=
        1
    od

;add arrays
kArr3[] = kArr1 + kArr2

## Map a Function to an Array

```
kArrRes maparray kArrSrc, "fun"
```

maps the k-rate 1-arg function in the string to every element of the vector.

Possible functions are for instance *abs*, *ceil*, *exp*, *floor*, *frac*, *int*, *log*, *log10*, *round*, *sqr*. This is a simple example:

```
kArrSrc[] fillarray 1, 2, 3, 4, 5
kArrRes[] init 5
kArrRes maparray kArrSrc, "sqrt"
```

See example for opcode *maparray*.

## Array Operations: min, max, sum, scale, slice

### Minimum and Maximum

```
kMin [,kMinIndx] minarray kArr
```

returns the smallest value in an array, and optionally its index.

```
kMax [,kMaxIndx] maxarray kArr
```

returns the largest value in an array, and optionally its index. See examples for opcodes *minarray* and *maxarray*.

## Sum

```
kSum sumarray kArr
```

returns the sum of all values in kArr. See example for opcode *sumarray*.

## Scale

```
scalearray kArr, kMin, kMax
```

scales all values in kArr between kMin and kMax.

```
kArr[] fillarray 1, 3, 9, 5, 6  
scalearray kArr, 1, 3
```

changes *kArr* to [1, 1.5, 3, 2, 2.25]. See example for opcode *scalearray*.

## Slice

```
slicearray kArr, iStart, iEnd
```

returns a slice of *kArr* from index *iStart* to index *iEnd* (included).

The array for receiving the slice must have been created in advance:

```
kArr[] fillarray 1, 2, 3, 4, 5, 6, 7, 8, 9  
kArr1[] init 5  
kArr2[] init 4  
kArr1 slicearray kArr, 0, 4 ;[1, 2, 3, 4, 5]  
kArr2 slicearray kArr, 5, 8 ;[6, 7, 8, 9]
```

See example for opcode *slicearray*.

## Arrays in UDOs

The dimension of an input array must be declared in two places:

- as k[] or k[][] in the type input list
- as kName[], kName[][] etc in the xin list.

For instance :

```
opcode FirstEl, k, k[]
;returns the first element of vector kArr
kArr[] xin
        xout    kArr[0]
endop
```

Here is an example of an array in an UDO. It uses the file *array\_udo.csd* [examples/array\_udo.csd].

### Example 5. Example of an array in an UDO

```
<CsoundSynthesizer>
<CsOptions>
-nml28
</CsOptions>
<CsInstruments>

    opcode FirstEl, k, k[]
    ;returns the first element of vector kArr
    kArr[] xin
    xout kArr[0]
    endop

    instr 1
    kArr[] fillarray 6, 3, 9, 5, 1
    kFirst FirstEl kArr
    printf "kFirst = %d\n", 1, kFirst
    turnoff
    endin

</CsInstruments>
<CsScore>
i 1 0 .1
</CsScore>
</CsoundSynthesizer>
```

# Pitch Converters

## Functions

Opcodes that provide common pitch functions are:

- *cent*
- *cpsmidinn*
- *cpsoct*
- *cpspch*
- *octave*
- *octcps*
- *octmidinn*
- *octpch*
- *pchmidinn*
- *pchoct*
- *semitone*

## Tuning Opcodes

Opcodes that provide tuning functions are:

- *cps2pch*
- *cpxpoch*
- *cpstun*
- *cpstuni*

# Real-time MIDI Support

Csound supports realtime MIDI input and output, as well as input from MIDI files. Realtime MIDI input is activated using the **-M** (or **--midi-device=DEVICE**) command line flag. You must specify the device number or name after the **-M**. For example to use device number 2, you would use something like:

```
csound -M2 myrtmidi.csd
```

You can find out the available devices by using an out of range device:

```
csound -M99 myrtmidi.csd
```

## Note

This will only work if the MIDI module can be accessed by device number. For alsal, you must first find the device name using:

```
cat /proc/asound/cards
```

You must then use something like:

```
csound -+rtmidi=alsa -M hw:3 myrtmidi.csd
```

Realtime MIDI output is activated using **-Q**, using device number or names as shown above.

You can also load a MIDI file using the **-F** or **--midifile=FILE** command line flag. The MIDI file is read in realtime, and behaves as if it was being performed or received in realtime. So the csound program is not aware if MIDI input comes from a MIDI file or directly from a MIDI interface.

Once realtime MIDI input and/or output has been activated, opcodes like *MIDI Input* and *MIDI Output* will have effect.

When MIDI input is enabled (with **-M** or **-F**), each incoming *noteon* message will generate a note event for an instrument which has the same number as the channel of the event (This means that MIDI controlled instruments are polyphonic by default, since each note will generate a new instance of the instrument.) If you have 1 instrument only, Csound works in omni mode, ie. it responds to all channels into that single instrument. If you have more than one instrument and instrs 1 - 16 , then by default instr 1 -> chn 1, instr 2 -> chn 2, unless you alter the mapping (see *massign* and *pgmassign* to change this behavior). If you have more than one instrument, but instr N in between 1 - 16 is missing, then chn N will be routed by default to the lowest order instrument.

See the *MIDI/Score Interoperability* opcodes for information on designing instruments which can be used from the score or driven by MIDI.

There are several realtime MIDI modules available, you must use the **-+rtmidi** flag (See **-+rtmidi**), to specify the module. The default module is portmidi which provides adequate MIDI I/O on all platforms, however for improved performance and reliability some platform specific modules are also provided.

Currently the midi modules available are:

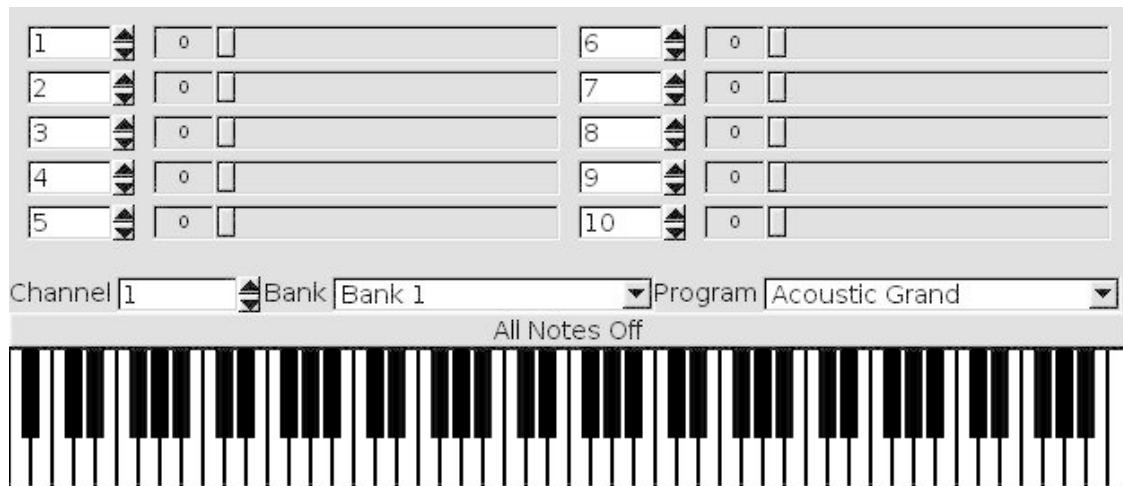

- *alsa* - To use the ALSA midi system (Linux only)
- *winmme* - To use the windows MME system (Windows only)
- *portmidi* - To use the portmidi system (all platforms). This is the default setting.
- *virtual* - To use a virtual graphical keyboard (See below) as MIDI input (all platforms)

### Tip

When csound runs, it will process the score and then quit. If there are no events in the score, Csound will exit immediately. If you want to use only MIDI events instead of score events, you need to tell Csound to run for a certain amount of time. This can be done with a dummy *f-statement* like "f 0 3600".

## Virtual MIDI Keyboard

Virtual MIDI keyboard.

The virtual MIDI keyboard module (activated using `-+rtmidi=virtual` on the command line flags) provides a way of sending realtime MIDI information to Csound without the need of a MIDI device. It can send note information, control changes, bank and program changes on a specified channel. The MIDI information from the virtual keyboard is processed by Csound in exactly the same way as MIDI information that comes from the other MIDI drivers, so if your Csound orchestra is designed to work with hardware MIDI devices, this will also work.

For the device flag (-M), the virtual keyboard uses this to take in the name of a keyboard mapping file. Like all MIDI drivers, a device must be given to activate the driver. If you would like to just use the default settings of the keyboard, simply passing in 0 (i.e. `-M0`) and the virtual keyboard will use its default settings. If instead of the 0 a name of a file is given, the keyboard will attempt to load the file as a keyboard mapping. If the file could not be opened or read correctly, the default settings will be used.

Keyboard Mapping files allow the user to customize the name and number of banks as well as the name and number of programs per bank. The following example keyboard mapping (named `keyboard.map`) has inline comments on the file format. This file is also available with the Csound source distribution in

the InOut/virtual\_keyboard folder.

```
# Custom Keyboard Map for Virtual Keyboard
# Steven Yi
#
# USAGE
#
# When using the Virtual Keyboard, you can supply a filename for a mapping
# of banks and programs via the -M flag, for example:
#
# csound -+rtmidi=virtual -Mkeyboard.map my_project.cs
#
# INFORMATION ON THE FORMAT
#
# -lines that start with '#' are comments
# -lines that have [] start new bank definitions,
#   the contents are bankNum=bankName, with bankNum=[1,16384]
# -lines following bank statements are program definitions
#   in the format programNum=programName, with programNum=[1,128]
# -bankNumbers and programNumbers are defined in this file
#   starting with 1, but are converted to midi values (starting
#   with 0) when read
#
# NOTES
#
# -if an invalid bank definition is found, all program
#   definitions that follow will be ignored until a new
#   valid bank definition is found
# -if a valid bank is defined by no valid programs found
#   for that bank, it will default to General MIDI program
#   definitions
# -if an invalid program definition is found, it will be
#   ignored

[1=My Bank]
1=My Test Patch 1
2=My Test Patch 2
30=My Test Patch 30

[2=My Bank2]
1=My Test Patch 1(bank2)
2=My Test Patch 2(bank2)
30=My Test Patch 30(bank3)
```

The ten sliders up top are by default set to MIDI Controller number 1-10 though they can be changed to whatever one wishes to use. The controller numbers and values of each slider are set per channel, so one may use different settings and values for each channel.

By default there are 128 banks and for each bank 128 patches defaulting to General Midi names. The MIDI bank standard uses 14-bit resolution to support 16384 possible banks, but the bank numbers by default are 0-127. To use values higher than 127, one should use a custom keyboard map and set the desired bank number value for the bank name. The virtual keyboard will correctly transmit the bank number as MSB and LSB with controller numbers 0 and 32.

Beyond the input available from interacting with the GUI via mouse, one may also trigger off MIDI notes by using the ASCII keyboard when the virtual keyboard window is focused. The layout is done much like a tracker and offers two octaves and a major third to trigger, starting from Middle-C (MIDI note 60). The ASCII keyboard MIDI note values are given in the following table.

**Table 5. ASCII Keyboard MIDI Note Values**

| Keyboard Key | MIDI Value |
|--------------|------------|
| z            | 60         |
| s            | 61         |
| x            | 62         |
| d            | 63         |

| Keyboard Key | MIDI Value |
|--------------|------------|
| c            | 64         |
| v            | 65         |
| g            | 66         |
| b            | 67         |
| h            | 68         |
| n            | 69         |
| j            | 70         |
| m            | 71         |
| q            | 72         |
| 2            | 73         |
| w            | 74         |
| 3            | 75         |
| e            | 76         |
| r            | 77         |
| 5            | 78         |
| t            | 79         |
| 6            | 80         |
| y            | 81         |
| 7            | 82         |
| u            | 83         |
| i            | 84         |
| 9            | 85         |
| o            | 86         |
| 0            | 87         |
| p            | 88         |

Here's an example of usage of the virtual MIDI keyboard. It uses the file *virtual.csd* [examples/virtual.csd].

## MIDI input

The following opcodes can receive MIDI information:

- MIDI information for any instruments: *aftouch*, *chanctrl* and *polyaft*, *pchbend*.
- MIDI information for MIDI-triggered instruments: *veloc*, *midictrl* and *notnum*. See also *Converters*.
- MIDI Controller input for any instrument: *ctrl7*, *ctrl14* and *ctrl21*.
- MIDI Controller input for MIDI-triggered instruments only: *midic7*, *midic14* and *midic21*.
- MIDI controller value initialization: *initc7*, *initc14*, *initc21* and *ctrlinit*.
- Generic MIDI input: *midiin*.

*massign* can be used to specify the csound instrument to be triggered by a particular MIDI channel. *pg-massign* can be used to assign a csound instrument to a specific MIDI program.

## MIDI Message Output

Opcodes that produce MIDI output are:

- *mdelay*
- *nрpn*
- *outiat*
- *outic*
- *outic14*
- *outipat*
- *outipb*
- *outipc*

- *outkat*
- *outkc*
- *outkc14*
- *outkpat*
- *outkpb*
- *outkpc*
- *midiout*

## Generic Input and Output

Opcodes for generic MIDI input and output are *midiin* and *midiout*.

## Converters

The following opcodes can convert MIDI information from a MIDI-triggered instrument instance:

- MIDI note number to frequency converters: *cpsmidi*, *cpsmidib*, *cpstmid*, *octmidi*, *octmidib*, *pchmidi* and *pchmidib*.
- MIDI velocity to amplitude converters: *ampmidi* and *ampmidid*.

## Event Extenders

Opcodes that let one extend the duration of an event are:

- *release*
- *xtratim*

## Note-on/Note-off Output

Opcodes to output MIDI note on or off messages are:

- *midion*
- *midion2*
- *moscil*
- *noteoff*
- *noteon*
- *noteondur*

- *noteondur2*

## MIDI/Score Interoperability opcodes

The following opcodes can be used to design instruments that work interchangably for real-time MIDI and score events:

- *midichannelaftertouch*
- *midichn*
- *midicontrolchange*
- *mididefault*
- *midinoteoff*
- *midinoteoncps*
- *midinoteonkey*
- *midinoteonoct*
- *midinoteonpch*
- *midipitchbend*
- *midipolyaftertouch*
- *midiprogramchange*.

### Adapting a score-activated Csound instrument.

To adapt an ordinary Csound instrument designed for score activation for score/MIDI interoperability:

- Change all *linen*, *linseg*, and *expseg* opcodes to *linenr*, *linsegr*, and *expsegr*, respectively, except for a de-clicking or damping envelope. This will not materially change score-driven performance.
- Add the following lines at the beginning of the instrument definition:

```
; Ensures that a MIDI-activated instrument  
; will have a positive p3 field.  
mididefault 60, p3  
; Puts MIDI key translated to cycles per  
; second into p4, and MIDI velocity into p5  
midinoteoncps p4, p5
```

Obviously, *midinoteoncps* could be changed to *midinoteonoct* or any of the other options, and the choice of p-fields is arbitrary.

## MIDI Realtime Input/Ouput command line options

New *MIDI I/O flags* in Csound 5.02, can replace most uses of these MIDI interop opcodes, and make usage easier.

# System Realtime Messages

Opcodes for System Realtime MIDI messages are: *mclock* and *mrtmsg*.

## Slider Banks

Opcodes for slider banks of MIDI controls are:

- *slider8*
- *slider8f*
- *slider16*
- *slider16f*
- *slider32*
- *slider32f*
- *slider64*
- *slider64f*
- *s16b14*
- *s32b14*
- *sliderKawai*

Opcodes for storing slider banks of MIDI controls to tables are:

- *slider8table*
- *slider8tablef*
- *slider16table*
- *slider16tablef*
- *slider32table*
- *slider32tablef*
- *slider64table*
- *slider64tablef*

---

# Spectral Processing

See the section *Additive Synthesis/Resynthesis* for the basic resynthesis opcodes.

## Short-time Fourier Transform (STFT) Re-synthesis

### Use of PVOC-EX files with the old Csound pvoc opcodes

All the original pvoc opcodes can now read a PVOC-EX file, as well as the native non-portable file format. As the PVOC-EX file uses a double-size analysis window, users may find that this gives a useful improvement in quality, for some sounds and processes, despite the fact that the resynthesis does not use the same window size.

Apart from the window size parameter, the main difference between the original .pv format and PVOC-EX is in the amplitude range of analysis frames. While rescaling is applied, so that no significant difference in output level is experienced, whichever file format is used, some slight loss of amplitude can still arise, as the double window usage itself modifies frame amplitudes, of which the resynthesis code is unaware. Note that all the original pvoc opcodes expect a mono analysis file, and multi-channel PVOC-EX files will accordingly be rejected.

Opcodes that implement STFT resynthesis are:

- *mincer*
- *temposcal*
- *tableseg*
- *pvadd*
- *pbufread*
- *pvcross*
- *pvinterp*
- *pvoc*
- *pvread*
- *tableseg*
- *tablexseg*
- *vpvoc*

Use the utility *PVANAL* to generate pv analysis files.

# Linear Predictive Coding (LPC) Resynthesis

The linear predictive coding resynthesis opcodes are:

- *lpfreson*
- *lpinterp*
- *lpread*
- *lpreson*
- *lpslot*

LPC analysis files can be created using the *LPANAL* utility.

# Non-standard Spectral Processing

These units generate and process non-standard signal data types, such as down-sampled time-domain control signals and audio signals, and their frequency-domain (spectral) representations. The data types (*d-*, *w-*) are self-defining, and the contents are not processable by any other Csound units.

The opcodes for non-standard spectral processing are *specaddm*, *specdiff*, *specdisp*, *specfilt*, *spechist*, *specptrk*, *specscal*, *specsum*, and *spectrum*.

# Tools for Real-time Spectral Processing (pvs opcodes)

With these opcodes, two new core facilities are added to Csound. They offer improved audio quality, and fast performance, enabling high-quality analysis and resynthesis (together with transformations) to be applied in real-time to live signals. The original Csound phase vocoder remains unaltered; the new opcodes use an entirely separate set of functions based on “pvoc.c” in the CARL distribution, written by Mark Dolson.

The Csound *dnoise* and *srconv* utilities (also by Dolson, from CARL) also use this pvoc engine. CARL pvoc is also the basis for the phase vocoder included in the Composer's Desktop Project. A few small but important modifications have been made to the original CARL code to support real-time streaming.

1. Support for the new PVOC-EX analysis file format. This is a fully portable (cross-platform) open file format, supporting three analysis formats, and multi-channel signals. Currently only the standard amplitude+frequency format has been implemented in the opcodes, but the file format itself supports amplitude+phase and complex (real-imaginary) formats. In addition to the new opcodes, the original Csound pvoc opcodes have been extended (and thereby with enhanced audio quality in some cases) to read PVOC-EX files as well as the original (non-portable) format.

Full details of the structure of a PVOC-EX file are available via the website: <http://www.cs.bath.ac.uk/~jpff/NOS-DREAM/researchdev/pvocex/pvocex.html>. This site also gives details of the freely available console programs *pvoce* and *pvoce2* which can be used to create PVOC-EX files in all supported formats.

2. A new frequency-domain signal type, fully streamable, with *f* as the leading character. In this document it is conveniently referred to as an *fsig*. Primary support for *fsigs* is provided by the opcodes

pvsanal and pvsynth, which perform conventional phase vocoder overlap-add analysis and resynthesis, independently of the orchestra control-rate. The only requirement is that the control-rate kr be higher than or equal to the analysis rate, which can be expressed by the requirement that ksmpls <= overlap, where overlap is the distance in samples between analysis frames, as specified for pvsanal. As overlap is typically at least 128, and more usually 256, this is not an onerous restriction in practice. The opcode pvsinfo can be used at init time to acquire the properties of an fsig.

The fsig enables the nominal separation between the analysis and resynthesis stages of the phase vocoder to be exposed to the Csound programmer, so that not only can alternatives be employed for either or both of these stages (not only oscillator-bank resynthesis, but also the generation of synthetic fsig streams), but opcodes, operating on the fsig stream, can themselves become more elemental. Thus the fsig enables the creation of a true streaming plugin framework for frequency domain signals. With the old pvoc opcodes, each opcode is required to act as a resynthesiser, so that facilities such as pitch scaling are duplicated in each opcode; and in many cases the opcodes are parameter-rich. The separation of analysis and synthesis stages by means of the fsig encourages the development of a wide range of simple building-block opcodes implementing one or two functions, with which more elaborate processes can be constructed.

This is very much a preliminary and experimental release, and it is possible that the precise definition of the opcodes may change, in response to user feedback. Also, clearly, many new possibilities for opcodes are opened up; these factors may also have a retrospective influence on the opcodes presented here.

Note that some opcode parameters currently have restricted or missing implementation. This is at least in part in order to keep the opcodes simple at this stage, and also because they highlight important design issues on which no decision has yet been made, and on which opinions from users are sought.

One important point about the new signal type is that because the analysis rate is typically much lower than kr, new analysis frames are not available on each k-cycle. Internally, the opcodes track ksmpls, and also maintain a frame counter, so that frames are read and written at the correct times; this process is generally transparent to the user. However, it means that k-rate signals only act on an fsig at the analysis rate, not at each k-cycle. The opcode pvsftw returns a k-rate flag that is set when new fsig data is valid.

Because of the nature of the overlap-add system, the use of these opcodes incurs a small but significant delay, or latency, determined by the window size (max(ifftsize,iwinsize)). This is typically around 23msecs. In this first release, the delay is slightly in excess of the theoretical minimum, and it is hoped that it can be reduced, as the opcodes are further optimized for real-time streaming.

The opcodes for real-time spectral processing are *pvsadsyn*, *pvsanal*, *pvscross*, *pvsfread*, *pvsftr*, *pvsftw*, *pvsinfo*, *pvsmaska*, and *pvsynth*.

In addition there are a number of opcodes available as plugins in Csound5, and in the core for Csound6. These are *pvtanal*, *pvsdiskin*, *pvcnt*, *pvsdemix*, *pvsfreeze*, *pvsbuffer*, *pvsbufread*, *pvsbufread2*, *pvscale*, *pvshift*, *pvsifd*, *pvsinit*, *pvsin*, *pvsout*, *pvsosc*, *pvsbin*, *pvsdisp*, *pvsfwrite*, *pvslock*, *pvsmix*, *pvssmooth*, *pvsfilter*, *pvsblur*, *pvcstencil*, *pvsarp*, *pvs voc*, *pvsmorph*, *pvsbandp*, *pvsbandr*, *pvsawarp*, *pvgain*, *pvs2tab*, *tab2pvs*.

A number of opcodes are designed to generate and process streaming partials tracks data. these are *partials*, *trcross*, *trfilter*, *trsplit*, *trmix*, *trscale*, *trshift*, *trlowest*, *trhighest*, *tradsyn*, *sinsyn*, *resyn*, *binit*

See the *Stacks* section for information on the stack opcodes which can stack f-signals.

## ATS Spectral Processing

These opcodes can read, transform and resynthesize ATS analysis files. Please note that you need the ATS application to produce analysis files. From the ATS Reference Manual:

"ATS is a software library of functions for spectral Analysis, Transformation, and Synthesis of sound based on a sinusoidal plus critical-band noise model. A sound in ATS is a symbolic object representing a spectral model that can be sculpted using a variety of transformation functions."

For more information on ATS visit: <http://www-ccrma.stanford.edu/~juan/ATS.html>.

ATS analysis files can be produced using the ATS software or the csound utility ATSA.

The opcodes for ATS processing are:

- *ATSinfo*: reads data out of the header of an ATS file.
- *ATSread*, *ATSreadnz*, *ATSBufread*, *ATSInterpread*, *ATSPartialtap*: read data from an ATS file or buffer.
- *ATSadd*, *ATSandnz*, *ATScross*, *ATSSinnoi*: Resynthesize sound.

## Loris Opcodes

### Note

These opcodes are an optional component of Csound5. You can check if they are installed by using the command 'csound -z' which lists all available opcodes.

The Loris family of opcodes wraps: *lorisread* which imports a set of bandwidth-enhanced partials from a SDIF-format data file, applying control-rate frequency, amplitude, and bandwidth scaling envelopes, and stores the modified partials in memory; *lorismorph*, which morphs two stored sets of bandwidth-enhanced partials and stores a new set of partials representing the morphed sound. The morph is performed by linearly interpolating the parameter envelopes (frequency, amplitude, and bandwidth, or noisiness) of the bandwidth-enhanced partials according to control-rate frequency, amplitude, and bandwidth morphing functions, and *lorisplay*, which renders a stored set of bandwidth-enhanced partials using the method of Bandwidth-Enhanced Additive Synthesis implemented in the Loris software, applying control-rate frequency, amplitude, and bandwidth scaling envelopes.

For more information about sound morphing and manipulation using Loris and the Reassigned Bandwidth-Enhanced Additive Model, visit the Loris web site at [www.cerlsoundgroup.org/Loris](http://www.cerlsoundgroup.org/Loris) [<http://www.cerlsoundgroup.org/Loris>].

## Examples

### Example 6. Play the partials wihtout modification

```
; Play the partials in clarinet.sdif
; from 0 to 3 sec with 1 ms fadetime
```

```
; and no frequency, amplitude, or
; bandwidth modification.
;
instr 1
    ktime    linseg      0, p3, 3.0      ; linear time function from 0 to 3 seconds
            lorisread   ktime, "clarinet.sdif", 1, 1, 1, 1, .001
    asig     lorisplay   1, 1, 1, 1
            out        asig
endin
```

### Example 7. Add tuning and vibrato

```
; Play the partials in clarinet.sdif
; from 0 to 3 sec with 1 ms fadetime
; adding tuning and vibrato, increasing the
; "breathiness" (noisiness) and overall
; amplitude, and adding a highpass filter.
;
instr 2
    ktime    linseg      0, p3, 3.0      ; linear time function from 0 to 3 seconds
            ;
            ; compute frequency scale for tuning
            ; (original pitch was G#4)
            ifscale =      cpspch(p4)/cpspch(8.08)

            ; make a vibrato envelope
    kvenv    linseg      0, p3/6, 0, p3/6, .02, p3/3, .02, p3/6, 0, p3/6, 0
    kvib     oscil       kvenv, 4, 1      ; table 1, sinusoid

    kbwenv   linseg      1, p3/6, 1, p3/6, 2, 2*p3/3, 2
            lorisread   ktime, "clarinet.sdif", 1, 1, 1, 1, .001
    a1       lorisplay   1, ifscale*kvib, 2, kbwenv
    a2       atone       a1, 1000       ; highpass filter, cutoff 1000 Hz
            out        a2
endin
```

The instrument in the first example synthesizes a clarinet tone from beginning to end using partials derived from reassigned bandwidth-enhanced analysis of a three-second clarinet tone, stored in a file, `clarinet.sdif`. The instrument in Example 2 adds tuning and vibrato to the clarinet tone synthesized by instr 1, boosts its amplitude and noisiness, and applies a highpass filter to the result. The following score can be used to test both of the instruments described above.

```
; make sinusoid in table 1
f 1 0 4096 10 1

; play instr 1
;      strt    dur
i 1    0      3
i 1    +      1
i 1    +      6
s

; play instr 2
;      strt    dur    ptch
i 2    1      3      8.08
i 2    3.5    1      8.04
i 2    4      6      8.00
i 2    4      6      8.07

e
```

### Example 8. Morph partials

```
; Morph the partials in clarinet.sdif into the
```

```
; partials in flute.sdif over the duration of
; the sustained portion of the two tones (from
; .2 to 2.0 seconds in the clarinet, and from
; .5 to 2.1 seconds in the flute). The onset
; and decay portions in the morphed sound are
; specified by parameters p4 and p5, respectively.
; The morphing time is the time between the
; onset and the decay. The clarinet partials are
; shifted in pitch to match the pitch of the flute
; tone (D above middle C).
;
instr 1
    ionset    =          p4
    idecay   =          p5
    itmorph   =          p3 - (ionset + idecay)
    ipshift   =          cpspch(8.02)/cpspch(8.08)

        ; clarinet time function, morph from .2 to 2.0 seconds
    ktcl    linseg    0, ionset, .2, itmorph, 2.0, idecay, 2.1
        ; flute time function, morph from .5 to 2.1 seconds
    ktfl    linseg    0, ionset, .5, itmorph, 2.1, idecay, 2.3
    kmurph  linseg    0, ionset, 0, itmorph, 1, idecay, 1
        lorisread  ktcl, "clarinet.sdif", 1, ipshift, 2, 1, .001
        lorisread  ktfl, "flute.sdif", 2, 1, 1, 1, .001
        lorismorph 1, 2, 3, kmurph, kmurph, kmurph
    asig    lorisplay 3, 1, 1, 1
        out      asig
endin
```

## Example 9. More morphing

```
; Morph the partials in trombone.sdif into the
; partials in meow.sdif. The start and end times
; for the morph are specified by parameters p4
; and p5, respectively. The morph occurs over the
; second of four pitches in each of the sounds,
; from .75 to 1.2 seconds in the flutter-tongued
; trombone tone, and from 1.7 to 2.2 seconds in
; the cat's meow. Different morphing functions are
; used for the frequency and amplitude envelopes,
; so that the partial amplitudes make a faster
; transition from trombone to cat than the frequencies.
; (The bandwidth envelopes use the same morphing
; function as the amplitudes.)
;
instr 2
    ionset    =          p4
    imorph   =          p5 - p4
    irelease  =          p3 - p5

    kttbn    linseg    0, ionset, .75, imorph, 1.2, irelease, 2.4
    ktmeow   linseg    0, ionset, 1.7, imorph, 2.2, irelease, 3.4

    kmfreq   linseg    0, ionset, 0, .75*imorph, .25, .25*imorph, 1, irelease, 1
    kmamp    linseg    0, ionset, 0, .75*imorph, .9, .25*imorph, 1, irelease, 1

        lorisread  kttbn, "trombone.sdif", 1, 1, 1, 1, .001
        lorisread  ktmeow, "meow.sdif", 2, 1, 1, 1, .001
        lorismorph 1, 2, 3, kmfreq, kmamp, kmamp
    asig    lorisplay 3, 1, 1, 1
        out      asig
endin
```

The instrument in the first morphing example performs a sound morph between a clarinet tone and a flute tone using reassigned bandwidth-enhanced partials stored in `clarinet.sdif` and `flute.sdif`.

The morph is performed over the sustain portions of the tones, 2. seconds to 2.0 seconds in the case of the clarinet tone and .5 seconds to 2.1 seconds in the case of the flute tone. The time index functions, `ktcl` and `ktfl`, align the onset and decay portions of the tones with the specified onset and decay times for the morphed sound, specified by parameters `p4` and `p5`, respectively. The onset in the morphed sounds is

purely clarinet partial data, and the decay is purely flute data. The clarinet partials are shifted in pitch to match the pitch of the flute tone (D above middle C).

The instrument in the second morphing example performs a sound morph between a flutter-tongued trombone tone and a cat's meow using reassigned bandwidth-enhanced partials stored in `trombone.sdif` and `meow.sdif`. The data in these SDIF files have been channelized and distilled to establish correspondences between partials.

The two sets of partials are imported and stored in memory locations labeled 1 and 2, respectively. Both of the original sounds have four notes, and the morph is performed over the second note in each sound (from .75 to 1.2 seconds in the flutter-tongued trombone tone, and from 1.7 to 2.2 seconds in the cat's meow). The different time index functions, `kttbn` and `ktmeow`, align those segments of the source and target partial sets with the specified morph start, morph end, and overall duration parameters. Two different morphing functions are used, so that the partial amplitudes and bandwidth coefficients morph quickly from the trombone values to the cat's-meow values, and the frequencies make a more gradual transition. The morphed partials are stored in a memory location labeled 3 and rendered by the subsequent `lorisplay` instruction. They could also have been used as a source for another morph in a three-way morphing instrument. The following score can be used to test both of the instruments described above.

```
; play instr 1
;      strt   dur   onset   decay
i 1     0       3     .25    .15
i 1     +       1     .10    .10
i 1     +       6     1.     1.
s

; play instr 2
;      strt   dur   morph_start   morph_end
i 2     0       4     .75    2.75
e
```

## Credits

This implementation of the Loris unit generators was written by Kelly Fitz ([loris@cerlsoundgroup.org](mailto:loris@cerlsoundgroup.org) [<mailto:loris@cerlsoundgroup.org>]).

It is patterned after a prototype implementation of the `lorisplay` unit generator written by Corbin Champion, and based on the method of Bandwidth-Enhanced Additive Synthesis and on the sound morphing algorithms implemented in the Loris library for sound modeling and manipulation. The opcodes were further adapted as a plugin for Csound 5 by Michael Gogins.

## Array-based spectral opcodes

### Note

These opcodes are designed to work with k-rate arrays for spectral data manipulation.

- `fft`,
- `fftinv`,
- `rfft`,
- `rifft`,

- *pvs2array*,
- *pvsfromarray*,
- *cplxprod*,
- *rect2pol*,
- *pol2rect*,
- *window*,
- *r2c*,
- *c2r*,
- *mags*, and
- *phs*.

# Strings

String variables are variables with a name starting with S or gS (for a local or global string variable, respectively), and can store any string with a maximum length defined by the -+max\_str\_len command line flag (255 characters by default). These variables can be used as input argument to any opcode that expects a quoted string constant, and can be manipulated at initialization or performance time with the opcodes listed below.

It is also possible to use string p-fields. The string p-field can be used by many orchestra op-codes directly, or it can be copied to a string variable first:

```
a1      diskin2 p5, 1  
  
Sname strget p5  
a1      diskin2 Sname, 1
```

Strings within Csound can be expressed using traditional double quotes (" "), and also using {{ }}. The second method is useful to allow ';' and '\$' characters within the string without having to use ASCII codes.

## Note

String variables and related opcodes are not available in Csound versions older than 5.00.

Strings can also be linked to a number using *strset* and *strget*.

Csound 5 also has improvements in parsing string constants. It is possible to specify a multi-line string by enclosing it within {{ }} instead of the usual double quote characters (note that the length of string constants is not limited, and is not affected by the -+max\_str\_len option), and the following escape sequences are automatically converted:

- \a alert bell
- \b backspace
- \n new line
- \r carriage return
- \t tab
- \\ a single '\' character
- \nnn the character of which the ASCII code (in octal) is nnn

It can be useful together with the *system* opcode:

```
instr 1  
; csound5 lets you make a string with line returns inside double brackets  
system {{ ps  
date  
cd ~/Desktop  
pwd  
ls -l
```

```
        whois csounds.com
    }
endin
```

And the *python opcodes*, among others:

```
pyruni {{
import random

pool = [(1 + i/10.0) ** 1.2 for i in range(100)]

def get_number_from_pool(n, p):
    if random.random() < p:
        i = int(random.random() * len(pool))
        pool[i] = n
    return random.choice(pool)
}}
```

## String Manipulation Opcodes

These opcodes perform operations on string variables (note: most of the opcodes run at init time only, and have a version with a "k" suffix that runs at both init and performance time; exceptions to this rule include puts and strget):

- *strcpy* and *strcpyk* - Assigns to a string variable.
- *strcat* and *strcatk* - Concatenates strings, and stores the result in a variable.
- *strcmp* and *strcmpk* - Compares strings.
- *strget* - Assigns to a string variable, from strset table at the specified index, or string score p-field.
- *strlen* and *strlenk* - Returns the length of a string.
- *sprintf* - printf-style formatted output conversion, storing the result in a string variable.
- *sprintfk* - printf-style formatted output conversion, storing the result in a string variable at k-rate.
- *puts* - Prints a string constant or variable.
- *strindex* and *strindexk* - Returns the first occurrence of a string in another string.
- *strrindex* and *strrindexk* - Returns the last occurrence of a string in another string.
- *strsub* and *strsubk* - Returns a substring of the input string.

## String Conversion Opcodes

These opcodes convert string variables (note: most of the opcodes run at init time only, and have a version with a "k" suffix that runs at both init and performance time; exceptions to this rule include puts and strget):

- *strtod* and *strtodk* - Converts string value to a floating point value at i-rate.
- *strtol* and *strtolk* - Converts string value to signed integer at i-rate.
- *strchar* and *strchark* - Returns the ASCII code of a character in a string.

- *strlower* and *strlowerk* - Converts a string to lower case.
- *struprupper* and *struprperk* - Converts a string to upper case.

---

# Vectorial Opcodes

The vectorial opcode family is designed to allow sections of f-tables to be treated as vectors for diverse operations on them.

## Tables of vectors operators

The following Vectorial opocodes support read/write access to arrays of vectors (or arrays of arrays):

- *vtablei*
- *vtable1k*
- *vtablek*
- *vtablea*
- *vtablewi*
- *vtablewk*
- *vtablewa*
- *vtabi*
- *vtabk*
- *vtaba*
- *vtabwi*
- *vtabwk*
- *vtabwa*

## Operations Between a Vectorial and a Scalar Signal

These opcodes perform numeric operations between a vectorial control signal (hosted inside a function table), and a scalar signal. Result is a new vector that overrides old values of the table. There are k-rate and i-rate versions of the opcodes.

All these operators are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2*, etc.

Operations Between a Vectorial and a Scalar Signal:

- *vadd*
- *vmult*

- *vpow*
- *vexp*
- *vadd\_i*
- *vmult\_i*
- *vpow\_i*
- *vexp\_i*

## Operations Between two Vectorial Signals

These opcodes perform operations between two vectors, that is, each element of the first vector is processed with the corresponding element of the other vector. The result is a new vector that overrides the old values of the source vector.

Operations Between two Vectorial Signals:

- *vaddv*
- *vsubv*
- *vmultv*
- *vdivv*
- *vpowv*
- *vexpv*
- *vcopy*
- *vmap*
- *vaddv\_i*
- *vsubv\_i*
- *vmultv\_i*
- *vdivv\_i*
- *vpowv\_i*
- *vexpv\_i*
- *vcopy\_i*

All these operators are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2*, etc.

## Vectorial Envelope Generators

---

The opcodes to generate vectors containing envelopes are *vlinseg* and *vexpseg*.

These opcodes are similar to *linseg* and *expseg*, but operate with vectorial signals instead of scalar signals.

Output is a vector hosted by an f-table (that must be previously allocated), while each break-point of the envelope is actually a vector of values. All break-points must contain the same number of elements (*ielements*).

These operators are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2*, etc.

## Limiting and wrapping of vectorial control signals

The opcodes to perform limiting and wrapping of elements within a vector are:

- *vlimit*
- *vwrap*
- *vmirror*

These opcodes are similar to *limit*, *wrap* and *mirror*, but operate on a vector instead of a scalar signal. The old values of the vector contained in an f-table are over-written if they are out of min/max interval. If you want to keep the original values of the input vector, use the *vcopy* opcode to copy it in another table.

All these opcodes work at k-rate.

All these operators are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2* etc.

## Vectorial Control-rate Delay Paths

Vectorial Control-rate Delay Paths:

- *vdelayk*
- *vport*
- *vecdelay*

## Vectorial Random Signal Generators

These opcodes generate vectors of random numbers to be stored in tables. They generate a sort of 'vectorial band-limited noise'. All these opcodes work at k-rate.

Vectorial random signal generators: *vrandh* and *vrandi*.

Cellular automata vectors can be generated using: *vcella*.

---

# Zak Patch System

The zak opcodes are used to create a system for i-rate, k-rate or a-rate patching. The zak system can be thought of as a global array of variables. These opcodes are useful for performing flexible patching or routing from one instrument to another. The system is similar to a patching matrix on a mixing console or to a modulation matrix on a synthesizer. It is also useful whenever an array of variables is required.

The zak system is initialized by the *zakinit* opcode, which is usually placed just after the other global initializations: *sr*, *kr*, *ksmps*, *nchnls*. The *zakinit* opcode defines two areas of memory, one area for i- and k-rate patching, and the other area for a-rate patching. The *zakinit* opcode may only be called once. Once the zak space is initialized, other zak opcodes can be used to read from, and write to the zak memory space, as well as perform various other tasks.

Zak channels count from 0, so if you define 1 channel, the only valid channel is channel 0.

Opcodes for the zak patch system are:

- Audio Rate: *zacl*, *zakinit*, *zamod*, *zar*, *zarg*, *zaw* and *zawm*.
- Control Rate: *zkcl*, *zkmod*, *zkr*, *zkw*, and *zkwm*.
- At initialization: *zir*, *ziw* and *ziwm*

---

# Plugin Hosting

Csound currently hosts external plugins using *dssi4cs* (for LADSPA plugins) on Linux and *vst4cs* (for VST plugins) on Windows and Mac OS X.

## DSSI and LADSPA for Csound

*dssi4cs* enables the use of DSSI and LADSPA plugin effects and synthesizers within Csound on Linux. The following opcodes are available:

- *dssiinit* - Loads a plugin.
- *dssiactivate* - Activates or deactivates a plugin if it has this facility
- *dssilist* - Lists all available plugins found in the LADSPA\_PATH and DSSI\_PATH global variables.
- *dssiaudio* - Process audio using a Plugin.
- *dssictls* - Send control information to a plugin's control port.

See the entry for *dssiinit* for a usage example.

### Note

Currently only LADSPA plugins are supported, but DSSI support is planned.

## VST for Csound

*vst4cs* enables the use of VST plugin effects and synthesizers within Csound. The following opcodes are available:

- *vstinit* - Loads a plugin.
- *vstaudio, vstaudiog* - Returns a plugin's output.
- *vstmidiout* - Sends MIDI data to a plugin.
- *vstparamset, vstparamget* - Sends and receives automation data to and from the plugin.
- *vstnote* - Sends a MIDI note with definite duration.
- *vstinfo* - Outputs the Parameter and Program names for a plugin.
- *vstbankload* - Loads an .fxb Bank.
- *vstprogset* - Sets a Program in an .fxb Bank.
- *vstedit* - Opens the GUI editor for the plugin, when available.

# OSC and Network

## OSC

OSC enables interaction between different audio processes, and in particular between Csound and other synthesis engines. The following opcodes are available:

- *OSCinit* - Start an OSC listener thread.
- *OSClisten* - Receive OSC messages.
- *OSCsendl* - Send an OSC message.

## Credits

By: John ffitch with the liblo library as inspiration and support.

## Network

The following opcodes can stream or receive audio through UDP:

- *sockrecv*
- *socksend*

## Remote Opcodes

The Remote opcodes enable transmission of score or MIDI events through a network, so remote instances (or a different local instance) can process them. The following opcodes are available:

- *insglobal* - Used to implement a remote orchestra.
- *insremot* - Used to implement a remote orchestra.
- *midiglobal* - Used to implement a remote MIDI orchestra.
- *midiremot* - Used to implement a remote MIDI orchestra.
- *remoteport* - Defines the port for use with the remote system.

---

# Mixer Opcodes

The Mixer family of opcodes provides a global mixer for Csound. The Mixer opcodes include *MixerSend* for sending (that is, mixing in) an arate signal from any instrument to a channel of a mixer buss, *MixerReceive* for receiving an arate signal from a channel of any mixer buss in any instrument, *MixerSetLevel* (krate) and *MixerSetLevel\_i* (irate) for controlling the level of the signal sent from a particular send to a particular buss, *MixerGetLevel* for reading (at krate) the level for sending a signal from a particular send to a particular buss, and *MixerClear* for resetting the busses to zero before the next kperiod of a performance.

---

# Signal Flow Graph Opcodes

These opcodes enable the use of signal flow graphs (AKA asynchronous data flow graphs) in Csound orchestras. Signals flow from the outlets of source instruments and are summed in the inlets of sink instruments. Signals may be krate, arate, or frate. Any number of outlets may be connected to any number of inlets. When a new instance of an instrument is instantiated during performance, the declared connections also are automatically instantiated.

Signal flow graphs simplify the construction of complex mixers, signal processing chains, and the like. They also simplify the re-use of "plug and play" instrument definitions and even entire sub-orchestras, which can simply be #included and then "plugged in" to existing orchestras.

Note that inlets and outlets are defined in instruments without reference to how they are connected. Connections are defined in the orchestra header. It is this separation that enables plug-in instruments.

Inlets must be named. Instruments may be named or numbered, but in either case each source instrument must be defined in the orchestra before any of its sinks. Naming instruments makes it easier to connect outlets and inlets in any higher-level orchestra to inlets and outlets in any lower-level #included orchestra.

The signal flow graph opcodes include: *outleta*, for sending an arate signal from any instrument out a named port. *outletk*, for sending a krate signal from any instrument out a named port. *outletkid*, similar to outletk, but receiving a krate signal only from an identified instance of a port. *outletf*, for sending an frate signal from any instrument out a named port. *inleta*, for receiving an arate signal through a named port. *inletk*, for receiving a krate signal through a named port. *inletkid*, similiar to inletk, but transmitting a signal only between inlet and outlet opcodes . *inletf*, for receiving an frate signal through a named port. *connect*, for routing the signal from a named outlet in a source instrument to a named inlet in a sink instrument. *alwayson* for permanently activating an instrument from the orchestra header, without need of a score statement, e.g. for use as an effect processor receiving inputs from a number of sources. *ftgenonce* for instantiating function tables from within instrument definitions, without need for f-statements in the score or ftgen opcodes in the orchestra header.

A typical scenario for the use of these opcodes would be something like this. A set of instruments would be defined, each in its own orchestra file, and each instrument would define inlet ports, outlet ports, and function tables within itself. Such instruments are completely self-contained. Then, a set of effects processors, such as equalizers, reverbs, compressors, and so on, would also be defined, each in its own file. Then, a customized master orchestra would #include the instruments and effects to be used, route the outputs of some instruments into one equalizer and the outputs of other effects into another equalizer, then route the outputs of both equalizers into a reverb, the output of the reverb into a compressor, and the output of the compressor into a stereo output soundfile.

## Example

Here is an example of the signal flow graph opcodes. It uses the file *signalflowgraph.csd* [examples/signalflowgraph.csd].

### Example 10. Example of the signal flow graph opcodes.

# Jacko Opcodes

These opcodes enable the use of Jack ports from within Csound orchestras and instruments. Ports can receive or send audio or MIDI data, and send note data.

The Jacko opcodes do not replace the Jack driver and Jack command-line options for Csound, nor do the Jacko opcodes work with them (hence the name "Jacko" instead of "Jack"). The Jacko opcodes are an independent facility that offers greater flexibility in signal routing.

In addition, the Jacko opcodes can work with the Jack system in "freewheeling" mode, which enables the use of Jack-enabled external synthesizers, such as Aeolus or Pianoteq, to render Csound pieces either faster or, even more importantly, slower than real time. This is extremely useful for rendering complex pieces without dropouts using instruments, such as Aeolus, that may not be available except through Jack.

The Jacko opcodes include: *JackoInit*, for initializing the current instance of Csound as a Jack client. *JackoInfo*, for printing information about the Jack daemon, its clients, their ports, and their connections. *JackoFreewheel*, for turning Jack's freewheeling mode on or off. *JackoAudioInConnect*, for creating a connection from an external Jack audio output port to a Jack port in Csound. *JackoAudioOutConnect*, for creating a connection from a Jack port in Csound to an external Jack audio input port. *JackoMidiInConnect*, for creating a connection from an external Jack MIDI port. MIDI events from Jack are received by Csound's regular MIDI opcodes and MIDI interop system. *JackoMidiOutConnect*, for creating a connection from a Jack port in Csound to an external Jack MIDI input port. *JackoOn*, for turning Jack ports in Csound on or off. *JackoAudioIn*, for receiving audio from a Jack input port in Csound, which in turn has received the audio from its connected external port. *JackoAudioOut*, for sending audio to a Jack output port in Csound, which in turn will send the audio on to its connected external port. *JackoMidiOut*, for sending MIDI channel messages to a Jack output port in Csound, which in turn will send the MIDI on to its connected external port. *JackoNoteOut*, for sending a note (with duration) to a Jack output port in Csound, which in turn will send the note on to its connected external port. *JackoTransport*, for controlling the Jack transport.

A typical scenario for the use of the Jacko opcodes would be something like this.

## Example

Here is an example of the Jacko opcodes. It uses the file *jacko.csd* [examples/jacko.csd].

### Example 11. Example of the Jacko opcodes.

# Lua Opcodes

The purposes of the Lua opcodes are:

1. Make it possible to write Csound code in a user-friendly, high-level language with full lexical scoping, structures and classes, and support for functional programming, using LuajIT (the Lua programming language, implemented with a just-in-time compiler and foreign function interface).
2. Require the installation of no third party software packages, or at least a minimum installation; also, require no build system or external compilation.
3. Run *really fast*; typically, almost as fast as compiled C code, and several times faster than user-defined opcodes.

Using the Lua opcode family, you can interact with the Lua interpreter and just-in-time compiler (luajit) embedded in Csound as follows:

1. Execute any arbitrary block of Lua code (the *lua\_exec* opcode),
2. Define an opcode in Lua taking any number or type of parameters, and returning any number or type of parameters (the *lua\_opdef* opcode),
3. Call a Lua opcode at i-rate (the *lua\_iopcall* opcode),
4. Call a Lua opcode at i-rate and k-rate (the *lua\_ikopcall* opcodes), or
5. Call a Lua opcode at i-rate and a-rate (the *lua\_iaopcall* opcode).

Lua is Portuguese for "moon." And Lua (<http://www.lua.org>) is a lightweight, efficient dynamic programming language, designed for embedding in C/C++ and extending with C/C++. Lua has a stack-based calling mechanism and provides a toolkit of features (tables, metatables, anonymous functions, and closures) with which many styles of object-oriented and functional programming may be implemented. Lua's syntax is only slightly harder than Python's.

Lua is already one of the fastest dynamic languages; yet LuajIT by Mike Pall (<http://luajit.org>) goes much further, giving Lua a just-in-time optimizing trace compiler for Intel architectures. LuajIT includes an efficient foreign function interface (FFI) with the ability to define C arrays, structures, and other types in Lua. The speed of LuajIT/FFI ranges from several times as fast as Lua, to faster (in some contexts) than optimized C.

## Example

Here is an example of a Lua opcode, implementing a Moog ladder filter. For purposes of comparison, a user-defined opcode and the native Csound opcode that compute the same sound using the same algorithm also are shown, and timed.. The example uses the file *luamoog.csd* [examples/luamoog.csd].

### Example 12. Example of a Lua opcode.

```

# Python Opcodes

## Introduction

Using the Python opcode family, you can interact with a Python interpreter embedded in Csound in five ways:

1. Initialize the Python interpreter (the *pyinit* opcodes),
2. Run a statement (the *pyrun* opcodes),
3. Execute a script (the *pyexec* opcodes),
4. Invoke a callable and pass arguments (the *pycall* opcodes),
5. Evaluate an expression (the *pyeval* opcodes), or
6. Change the value of a Python object, possibly creating a new Python object (the *pyassign* opcodes);

and you can do any of these things:

1. At i-time or at k-time,
2. In the global Python namespace, or in a namespace specific to an individual instance of a Csound instrument (local or "I" context),
3. And you can retrieve from 0 to 8 return values from callables that accept N parameters.

...this means that there are many Python-related opcodes. But all of these opcodes share the same *py* prefix, and have a regular naming scheme:

"py" + [optional context prefix] + [action name] + [optional x-time suffix]

## Orchestra Syntax

Blocks of Python code, and indeed entire scripts, can be embedded in Csound orchestras using the {{ and }} directives to enclose the script, as follows:

```
sr=44100
kr=4410
ksmps=10
nchnls=1
pyinit

giSinusoid ftgen 0, 0, 8192, 10, 1

pyruni {{
import random

pool = [(1 + i/10.0) ** 1.2 for i in range(100)]

def get_number_from_pool(n, p):
```

```
    if random.random() < p:
        i = int(random.random() * len(pool))
        pool[i] = n
    return random.choice(pool)
}

instr 1
    k1 oscil 1, 3, gisinusoid
    k2 pycall1 "get_number_from_pool", k1 + 2, p4
    printk 0.01, k2
endin
```

# Image processing opcodes

Here is a list of opcodes that read/write image files:

- *imagecreate*
- *imagesize*
- *imagegetpixel*
- *imagesetpixel*
- *imagesave*
- *imagedload*
- *imagefree*

---

# STK Opcodes

## Note

These opcodes are an optional component of Csound6. You can check if they are installed by using the command 'csound -z' which lists all available op-codes.

The STK opcodes can be built in several ways. If you are already building Csound, simply follow the directions at the top of the Opcodes/stk/stkOpcodes.cpp file.

The STK family of opcodes wraps:

- *STKBandedWG*
- *STKBeeThree*
- *STKBlowBotl*
- *STKBlowHole*
- *STKBowed*
- *STKBrass*
- *STKClarinet*
- *STKDrummer*
- *STKFlute*
- *STKFMVoices*
- *STKHevyMetl*
- *STKMandolin*
- *STKModalBar*
- *STKMoog*
- *STKPercFlut*
- *STKPlucked*
- *STKResonate*
- *STKRhodey*
- *STKSaxofony*
- *STKShakers*
- *STKSimples*
- *STKSitar*

- *STKStifKarp*
- *STKTubeBell*
- *STKVocForm*
- *STKWhistle*
- *STKWurley*

For more information about the STK opcodes, visit The Synthesis ToolKit in C++ (STK) web site at <https://ccrma.stanford.edu/software/stk>.

## Credits

This implementation of the STK unit generators was written by Perry R. Cook and Gary P. Scavone.

The opcodes were further adapted as a plugin for Csound 5 by Michael Gogins.

---

# Miscellaneous opcodes

Here is a list of opcodes that don't fall in any category:

- *system* - Call an external program via the system call.
- *modmatrix* - modulation matrix opcode with optimizations for sparse matrices.

---

# **Orchestra Opcodes and Operators**

## !=

!= — Determines if one value is not equal to another.

## Description

Determines if one value is not equal to another.

## Syntax

```
(a != b ? v1 : v2)
```

where  $a$ ,  $b$ ,  $v1$  and  $v2$  may be expressions, but  $a$ ,  $b$  not audio-rate.

## Performance

In the above conditional,  $a$  and  $b$  are first compared. If the indicated relation is true ( $a$  not equal to  $b$ ), then the conditional expression has the value of  $v1$ ; if the relation is false, the expression has the value of  $v2$ .

NB.: If  $v1$  or  $v2$  are expressions, these will be evaluated before the conditional is determined.

In terms of binding strength, all conditional operators (i.e. the relational operators (<, etc.), and ?, and :) are weaker than the arithmetic and logical operators (+, -, \*, /, && and //).

These are *operators* not *opcodes*. Therefore, they can be used within orchestra statements, but do not form complete statements themselves.

## Examples

Here is an example of the != operator. It uses the file *notequal.csd* [examples/notequal.csd].

### Example 13. Example of the != operator.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# #define

`#define` — Defines a macro.

## Description

Macros are textual replacements which are made in the orchestra as it is being read. The macro system in Csound is a very simple one, and uses the characters # and \$ to define and call macros. This can save typing, and can lead to a coherent structure and consistent style. This is similar to, but independent of, the *macro system in the score language*.

`#define NAME` -- defines a simple macro. The name of the macro must begin with a letter and can consist of any combination of letters and numbers. Case is significant. This form is limiting, in that the variable names are fixed. More flexibility can be obtained by using a macro with arguments, described below.

`#define NAME(a' b' c')` -- defines a macro with arguments. This can be used in more complex situations. The name of the macro must begin with a letter and can consist of any combination of letters and numbers. Within the replacement text, the arguments can be substituted by the form: \$A. In fact, the implementation defines the arguments as simple macros. There may be up to 5 arguments, and the names may be any choice of letters. Remember that case is significant in macro names.

## Syntax

```
#define NAME # replacement text #
#define NAME(a' b' c') # replacement text #
```

## Initialization

`# replacement text #` -- The replacement text is any character string (not containing a #) and can extend over multiple lines. The replacement text is enclosed within the # characters, which ensure that additional characters are not inadvertently captured.

## Performance

Some care is needed with textual replacement macros, as they can sometimes do strange things. They take no notice of any meaning, so spaces are significant. This is why, unlike the C programming language, the definition has the replacement text surrounded by # characters. Used carefully, this simple macro system is a powerful concept, but it can be abused.

## Examples

Here is a simple example of defining a macro. It uses the file `define.csd` [examples/define.csd].

### Example 14. Simple example of the define macro.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out   Audio in    No messages
-odac          -iadc     -d      ;;;RT audio I/O
; For Non-realtime output leave only the line below:
; -o define.wav -W ;; for file output any platform
</CsOptions>
<CsInstruments>

; Initialize the global variables.
sr = 44100
kr = 4410
ksmps = 10
nchnls = 1

; Define the macros.
#define VOLUME #5000#
#define FREQ #440#
#define TABLE #1#

; Instrument #1
instr 1
; Use the macros.
; This will be expanded to "a1 oscil 5000, 440, 1".
a1 oscil $VOLUME, $FREQ, $TABLE

; Send it to the output.
out a1
endin

</CsInstruments>
<CsScore>

; Define Table #1 with an ordinary sine wave.
f 1 0 32768 10 1

; Play Instrument #1 for two seconds.
i 1 0 2
e

</CsScore>
</CsoundSynthesizer>
```

Its output should include lines like this:

```
Macro definition for VOLUME
Macro definition for CPS
Macro definition for TABLE
```

Here is an example of defining a macro with arguments. It uses the file *define\_args.csd* [examples/*define\_args.csd*].

### Example 15. Example of the define macro with arguments.

```
<CsoundSynthesizer>
<CsOptions>

# #include

#include — Includes an external file for processing.

## Description

Includes an external file for processing.

## Syntax

```
#include "filename"
```

## Performance

It is sometimes convenient to have the orchestra arranged in a number of files, for example with each instrument in a separate file. This style is supported by the *#include* facility which is part of the macro system. A line containing the text

```
#include "filename"
```

where the character " can be replaced by any suitable character. For most uses the double quote symbol will probably be the most convenient. The file name can include a full path.

This takes input from the named file until it ends, when input reverts to the previous input. *Note:* Csound versions prior to 4.19 had a limit of 20 on the depth of included files and macros.

Another suggested use of *#include* would be to define a set of macros which are part of the composer's style.

An extreme form would be to have each instrument defines as a macro, with the instrument number as a parameter. Then an entire orchestra could be constructed from a number of *#include* statements followed by macro calls.

```
#include "clarinet"
#include "flute"
#include "bassoon"
$CLARINET(1)
$FLUTE(2)
$BASSOON(3)
```

It must be stressed that these changes are at the textual level and so take no cognizance of any meaning.

If the version of Csound is built with the CURL library the filename in an *#include* statement can be an URL, recognised by including the substring "://" in the name. This will include text via protocols such as http, https, and ftp.

## Examples

Here is an example of the include opcode. It uses the file *include.csd* [examples/include.csd], and *table1.inc* [examples/table1.inc].

### Example 16. Example of the include opcode.

```
/* table1.inc */  
; Table #1, a sine wave.  
f 1 0 16384 10 1  
/* table1.inc */
```

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# #undef

#undef — Un-defines a macro.

## Description

Macros are textual replacements which are made in the orchestra as it is being read. The macro system in Csound is a very simple one, and uses the characters # and \$ to define and call macros. This can save typing, and can lead to a coherent structure and consistent style. This is similar to, but independent of, the *macro system in the score language*.

#*undef NAME* -- undefines a macro name. If a macro is no longer required, it can be undefined with #*undef NAME*.

## Syntax

```
#undef NAME
```

## Performance

Some care is needed with textual replacement macros, as they can sometimes do strange things. They take no notice of any meaning, so spaces are significant. This is why, unlike the C programming language, the definition has the replacement text surrounded by # characters. Used carefully, this simple macro system is a powerful concept, but it can be abused.

# #ifdef

#ifdef — Conditional reading of code.

## Description

If a macro is defined then `#ifdef` can incorporate text into an orchestra upto the next `#end`. This is similar to, but independent of, the *macro system in the score language*.

## Syntax

```
#ifdef NAME  
....  
#else  
....  
#end
```

## Performance

Note that the `#ifdef` can be nested, like in the C preprocessor language.

## Examples

Here is a simple example of the conditional.

### Example 17. Simple example of the #ifdef form.

```
#define debug ##  
      instr 1  
#ifdef debug  
      print "calling oscil"  
#end  
      a1    oscil 32000,440,1  
      out   a1  
#endif
```

# \$NAME

\$NAME — Calls a defined macro.

## Description

Macros are textual replacements which are made in the orchestra as it is being read. The macro system in Csound is a very simple one, and uses the characters # and \$ to define and call macros. This can save typing, and can lead to a coherent structure and consistent style. This is similar to, but independent of, the *macro system in the score language*.

\$NAME -- calls a defined macro. To use a macro, the name is used following a \$ character. The name is terminated by the first character which is neither a letter nor a number. If it is necessary for the name not to terminate with a space, a period, which will be ignored, can be used to terminate the name. The string, \$NAME., is replaced by the replacement text from the definition. The replacement text can also include macro calls.

## Syntax

\$NAME

## Initialization

# replacement text # -- The replacement text is any character string (not containing a #) and can extend over multiple lines. The replacement text is enclosed within the # characters, which ensure that additional characters are not inadvertently captured.

## Performance

Some care is needed with textual replacement macros, as they can sometimes do strange things. They take no notice of any meaning, so spaces are significant. This is why, unlike the C programming language, the definition has the replacement text surrounded by # characters. Used carefully, this simple macro system is a powerful concept, but it can be abused.

## Examples

Here is an example of calling a macro. It uses the file *define.csd* [examples/define.csd].

### Example 18. An example of calling a macro.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## %

% — Modulus operator.

## Description

Arithmetic operators perform operations of change-sign (negate), don't-change-sign, logical AND logical OR, add, subtract, multiply and divide. Note that a value or an expression may fall between two of these operators, either of which could take it as its left or right argument, as in

$a + b * c$ .

In such cases three rules apply:

1. \* and / bind to their neighbors more strongly than + and #. Thus the above expression is taken as

$a + (b * c)$

with \* taking b and c and then + taking a and  $b * c$ .

2. + and # bind more strongly than &&, which in turn is stronger than ||:

$a \&\& b - c || d$

is taken as

$(a \&\& (b - c)) || d$

3. When both operators bind equally strongly, the operations are done left to right:

$a - b - c$

is taken as

$(a - b) - c$

Parentheses may be used as above to force particular groupings.

The operator % returns the value of  $a$  reduced by  $b$ , so that the result, in absolute value, is less than the absolute value of  $b$ , by repeated subtraction. This is the same as modulus function in integers. New in Csound version 3.50.

## Syntax

`a % b` (no rate restriction)

where the arguments  $a$  and  $b$  may be further expressions.

## Arguments

The arguments of % can be scalar values or k-rate one dimensional arrays (vectors), or any combination. If one of the arguments is an array, so is the value.

## Examples

Here is an example of the % operator. It uses the file *modulus.csd* [examples/modulus.csd].

### Example 20. Example of the % operator.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

Arithmetic on vectors is new in version 6.00

## &&

`&&` — Logical AND operator.

## Description

Arithmetic operators perform operations of change-sign (negate), don't-change-sign, logical AND logical OR, add, subtract, multiply and divide. Note that a value or an expression may fall between two of these operators, either of which could take it as its left or right argument, as in

`a + b * c.`

In such cases three rules apply:

1. `*` and `/` bind to their neighbors more strongly than `+` and `#`. Thus the above expression is taken as

`a + (b * c)`

with `*` taking `b` and `c` and then `+` taking `a` and `b * c`.

2. `+` and `#` bind more strongly than `&&`, which in turn is stronger than `||`:

`a && b - c || d`

is taken as

`(a && (b - c)) || d`

3. When both operators bind equally strongly, the operations are done left to right:

`a - b - c`

is taken as

`(a - b) - c`

Parentheses may be used as above to force particular groupings.

## Syntax

`a && b` (logical AND; not audio-rate)

where the arguments `a` and `b` may be further expressions.

## Examples

Here is an example of the Logical AND operator. It uses the file `opand.csd` [examples/opand.csd].

### Example 21. Example of the opand opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## See Also

-, +, //, \*, /, ^, %

**>**

> — Determines if one value is greater than another.

## Description

Determines if one value is greater than another.

## Syntax

```
(a > b ? v1 : v2)
```

where  $a$ ,  $b$ ,  $v1$  and  $v2$  may be expressions, but  $a$ ,  $b$  not audio-rate.

## Performance

In the above conditional,  $a$  and  $b$  are first compared. If the indicated relation is true ( $a$  greater than  $b$ ), then the conditional expression has the value of  $v1$ ; if the relation is false, the expression has the value of  $v2$ .

NB.: If  $v1$  or  $v2$  are expressions, these will be evaluated before the conditional is determined.

In terms of binding strength, all conditional operators (i.e. the relational operators ( $<$ , etc.), and  $?$ , and  $:$ ) are weaker than the arithmetic and logical operators ( $+$ ,  $-$ ,  $*$ ,  $/$ ,  $\&&$  and  $//$ ).

These are *operators* not *opcodes*. Therefore, they can be used within orchestra statements, but do not form complete statements themselves.

## Examples

Here is an example of the  $>$  operator. It uses the file *greaterthan.csd* [examples/greaterthan.csd].

### Example 22. Example of the $>$ operator.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

Arithmetic on vectors is new in version 6.00

---

**=**

= — Performs a simple assignment.

## Syntax

```
ares = xarg  
  
ires = iarg  
  
kres = karg  
  
ires, ... = iarg, ...  
  
kres, ... = karg, ...  
  
table [ kval] = karg
```

## Description

Performs a simple assignment.

## Initialization

= (simple assignment) - Put the value of the expression *iarg* (*karg*, *xarg*) into the named result. This provides a means of saving an evaluated result for later use.

From version 5.13 onwards the i- and k-rate versions of assignment can take a number of outputs, and an equal or less number of inputs. If there are less the last value is repeated as necessary.

From version 5.14 values can be assigned to elements of a vector with the square bracket form.

## Examples

Here is an example of the assign opcode. It uses the file *assign.csd* [examples/assign.csd].

### Example 30. Example of the assign opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

**==**

**==** — Compares two values for equality.

## Description

Compares two values for equality.

## Syntax

```
(a == b ? v1 : v2)
```

where  $a$ ,  $b$ ,  $v1$  and  $v2$  may be expressions, but  $a$ ,  $b$  not audio-rate.

## Performance

In the above conditional,  $a$  and  $b$  are first compared. If the indicated relation is true ( $a$  is equal to  $b$ ), then the conditional expression has the value of  $v1$ ; if the relation is false, the expression has the value of  $v2$ . (For convenience, a sole " $=$ " will function as " $= =$ ".)

NB.: If  $v1$  or  $v2$  are expressions, these will be evaluated before the conditional is determined.

In terms of binding strength, all conditional operators (i.e. the relational operators ( $<$ , etc.), and  $?$ , and  $:$ ) are weaker than the arithmetic and logical operators ( $+$ ,  $-$ ,  $*$ ,  $/$ ,  $\&&$  and  $//$ ).

These are *operators* not *opcodes*. Therefore, they can be used within orchestra statements, but do not form complete statements themselves.

## Examples

Here is an example of the **==** operator. It uses the file *equals.csd* [examples>equals.csd].

### Example 32. Example of the == operator.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## Λ

$\wedge$  — “Power of” operator.

## Description

Arithmetic operators perform operations of change-sign (negate), don't-change-sign, logical AND logical OR, add, subtract, multiply and divide. Note that a value or an expression may fall between two of these operators, either of which could take it as its left or right argument, as in

$a + b * c.$

In such cases three rules apply:

1.  $*$  and  $/$  bind to their neighbors more strongly than  $+$  and  $#$ . Thus the above expression is taken as

$a + (b * c)$

with  $*$  taking  $b$  and  $c$  and then  $+$  taking  $a$  and  $b * c$ .

2.  $+$  and  $#$  bind more strongly than  $\&\&$ , which in turn is stronger than  $\|$ :

$a \&\& b - c \| d$

is taken as

$(a \&\& (b - c)) \| d$

3. When both operators bind equally strongly, the operations are done left to right:

$a - b - c$

is taken as

$(a - b) - c$

Parentheses may be used as above to force particular groupings.

The operator  $\wedge$  raises  $a$  to the  $b$  power.  $b$  may not be audio-rate. Use with caution as precedence may not work correctly. See *pow*. (New in Csound version 3.493.)

## Syntax

```
a ^ b  (b not audio-rate)
```

where the arguments *a* and *b* may be further expressions.

## Examples

Here is an example of the `^` operator. It uses the file *raises.csd* [examples/raises.csd].

### Example 33. Example of the `^` operator.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>

**||**

|| — Logical OR operator.

## Description

Arithmetic operators perform operations of change-sign (negate), don't-change-sign, logical AND logical OR, add, subtract, multiply and divide. Note that a value or an expression may fall between two of these operators, either of which could take it as its left or right argument, as in

$a + b * c.$

In such cases three rules apply:

1. \* and / bind to their neighbors more strongly than + and #. Thus the above expression is taken as

$a + (b * c)$

with \* taking b and c and then + taking a and  $b * c$ .

2. + and # bind more strongly than &&, which in turn is stronger than ||:

$a \&\& b - c || d$

is taken as

$(a \&\& (b - c)) || d$

3. When both operators bind equally strongly, the operations are done left to right:

$a - b - c$

is taken as

$(a - b) - c$

Parentheses may be used as above to force particular groupings.

## Syntax

---

`a || b (logical OR; not audio-rate)`

# 0dbfs

0dbfs — Sets the value of 0 decibels using full scale amplitude.

## Description

Sets the value of 0 decibels using full scale amplitude.

## Syntax

```
0dbfs = iarg  
  
0dbfs
```

## Initialization

*iarg* -- the value of 0 decibels using full scale amplitude.

## Performance

The default is 32767, so all existing orcs *should* work.

Amplitude values in Csound are always relative to a "0dbfs" value representing the peak available amplitude before clipping. In the original Csound, this value was always 32767, corresponding to the bipolar range of a 16bit soundfile or 16bit AD/DA codec. This remains the *default* peak amplitude for Csound, for backward compatibility. The 0dbfs value enables Csound to produce appropriately scaled values to whatever output format is being used, whether 16bit integer, 24bit integer, 32bit floats, or even 32bit integers.

OdBFS can be defined in the header, to set the amplitude reference Csound will use, but it can also be used as a variable inside instruments like this:

```
ipeak = 0dbfs  
  
asig oscil 0dbfs, freq, 1  
out asig * 0.3 * 0dbfs
```

The purpose of the 0dbfs opcode is for people to start to code 0dbfs-relatively (and use the *ampdbfs()* opcodes a lot more!), rather than use explicit sample values. Using 0dbfs=1 is in accordance to industry practice, as ranges from -1 to 1 are used in most commercial plugin formats and in most other synthesis systems like Pure Data.

Floats written to a file, when *0dbfs = 1*, will in effect go through no range translation at all. So the numbers in the file are exactly what the orc says they are.

For more details on amplitude values in Csound, see the section *Amplitude values in Csound*

# Example

Here is an example of the 0dbfs opcode. It uses the file *0dbfs.csd* [examples/0dbfs.csd].

## Example 35. Example of the 0dbfs opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## Description

The bitwise operators perform operations of bitwise AND, bitwise OR, bitwise NOT and bitwise non-equivalence.

The priority of these operators is less binding than the arithmetic ones, but more binding than the comparisons.

Parentheses may be used as above to force particular groupings.

## Syntax

`~ a (bitwise NOT)`

where the argument *a* may be a further expression. It is converted to the nearest integer to machine precision and then the operation is performed.

## See Also

## #

# — Bitwise NON EQUIVALENCE operator.

## Description

The bitwise operators perform operations of bitwise AND, bitwise OR, bitwise NOT and bitwise non-equivalence.

The priority of these operators is less binding than the arithmetic ones, but more binding than the comparisons.

Parentheses may be used as above to force particular groupings.

## Syntax

```
a # b  (bitwise NON EQUIVALENCE)
```

where the arguments *a* and *b* may be further expressions. They are converted to the nearest integer to machine precision and then the operation is performed.

## See Also

&, /  $\neg$

# a

a — Converts a k-rate parameter to an a-rate value with interpolation.

## Description

Converts a k-rate parameter to an a-rate value with interpolation.

## Syntax

```
a(x) (control-rate args only)
```

where the argument within the parentheses may be an expression. Value converters perform arithmetic translation from units of one kind to units of another. The result can then be a term in a further expression.

## Examples

Here is an example of the a opcode. It uses the file *opa.csd* [examples/opa.csd].

### Example 38. Example of the a opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# abs

abs — Returns an absolute value.

## Description

Returns the absolute value of  $x$ .

## Syntax

```
abs(x) (no rate restriction)
```

where the argument within the parentheses may be an expression. Value converters perform arithmetic translation from units of one kind to units of another. The result can then be a term in a further expression.

## Examples

Here is an example of the abs opcode. It uses the file *abs.csd* [examples/abs.csd].

### Example 39. Example of the abs opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# active

active — Returns the number of active instances of an instrument.

## Description

Returns the number of active instances of an instrument with options to ignore releasing instances.

## Syntax

```
ir active insnum [,iopt [,inorel]]  
  
ir active Sinsname [,iopt [,inorel]]  
  
kres active kinsnum [,iopt [,inorel]]
```

## Initialization

*insnum* -- number or string name of the instrument to be reported

*Sinsname* -- instrument name

*iopt* -- select currently active (zero, default), or all every active (non zero)

*inorel* -- if non-zero ignore instruments in release phase (zero, default), only valid if iopts is zero.

## Performance

*kinsnum* -- number or string name of the instrument to be reported

*active* returns the number of active instances of instrument number *insnum*/*kinsnum* (or named instrument *Sinsname*). As of Csound 4.17 the output is updated at k-rate (if input arg is k-rate), to allow running count of instr instances.

As of Csound 5.17 if the instrument number is given as zero then all instruments are counted.

## Examples

Here is a simple example of the active opcode. It uses the file *active.csd* [examples/active.csd].

### Example 40. Simple example of the active opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>

## adsr

adsr — Calculates the classical ADSR envelope using linear segments.

## Description

Calculates the classical ADSR envelope using linear segments.

## Syntax

```
ares adsr iatt, idec, islev, irel [, idel]
```

```
kres adsr iatt, idec, islev, irel [, idel]
```

## Initialization

*iatt* -- duration of attack phase

*idec* -- duration of decay

*islev* -- level for sustain phase

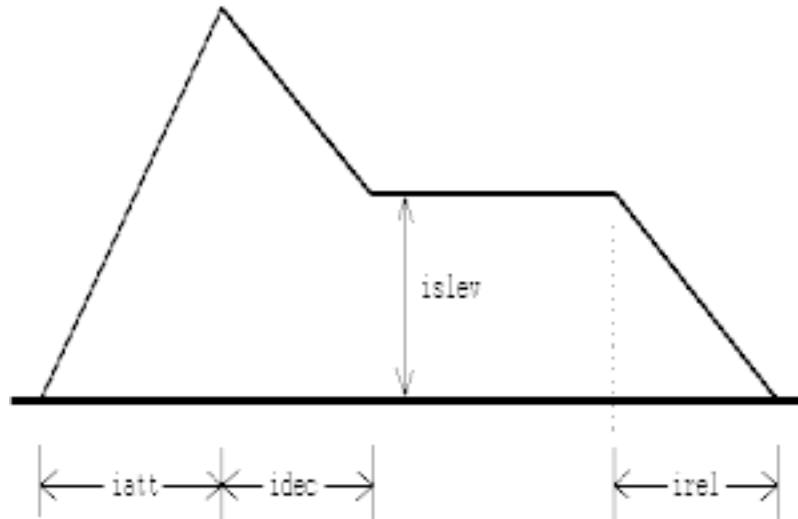

*irel* -- duration of release phase

*idel* -- period of zero before the envelope starts

## Performance

The envelope generated is the range 0 to 1 and may need to be scaled further, depending on the amplitude required. If using *0dbfs* = 1, scaling down will probably be required since playing more than one note might result in clipping. If not using *0dbfs*, scaling to a large amplitude (e.g. 32000) might be required.

The envelope may be described as:

Picture of an ADSR envelope.

The length of the sustain is calculated from the length of the note. This means *adsr* is not suitable for use with MIDI events. The opcode *madsr* uses the *linsegr* mechanism, and so can be used in MIDI applications.

*adsr* is new in Csound version 3.49.

## Examples

Here is an example of the *adsr* opcode. It uses the file *adsr.csd* [examples/adsr.csd].

### Example 43. Example of the *adsr* opcode.

# adsyn

adsyn — Output is an additive set of individually controlled sinusoids, using an oscillator bank.

## Description

Output is an additive set of individually controlled sinusoids, using an oscillator bank.

## Syntax

```
ares adsyn kamod, kfmod, ksmod, ifilcod
```

## Initialization

*ofilcod* -- integer or character-string denoting a control-file derived from analysis of an audio signal. An integer denotes the suffix of a file *adsyn.m* or *pvoc.m*; a character-string (in double quotes) gives a file-name, optionally a full pathname. If not fullpath, the file is sought first in the current directory, then in the one given by the environment variable *SADIR* (if defined). *adsyn* control contains breakpoint amplitude- and frequency-envelope values organized for oscillator resynthesis, while *pvoc* control contains similar data organized for fft resynthesis. Memory usage depends on the size of the files involved, which are read and held entirely in memory during computation but are shared by multiple calls (see also *lspread*).

## Performance

*kamod* -- amplitude factor of the contributing partials.

*kfmod* -- frequency factor of the contributing partials. It is a control-rate transposition factor: a value of 1 incurs no transposition, 1.5 transposes up a perfect fifth, and .5 down an octave.

*ksmod* -- speed factor of the contributing partials.

*adsyn* synthesizes complex time-varying timbres through the method of additive synthesis. Any number of sinusoids, each individually controlled in frequency and amplitude, can be summed by high-speed arithmetic to produce a high-fidelity result.

Component sinusoids are described by a control file describing amplitude and frequency tracks in millisecond breakpoint fashion. Tracks are defined by sequences of 16-bit binary integers:

```
-1, time, amp, time, amp,...  
-2, time, freq, time, freq,...
```

such as from heterodyne filter analysis of an audio file. (For details see *hetro*.) The instantaneous amplitude and frequency values are used by an internal fixed-point oscillator that adds each active partial into an accumulated output signal. While there is a practical limit (limit removed in version 3.47) on the number of contributing partials, there is no restriction on their behavior over time. Any sound that can be described in terms of the behavior of sinusoids can be synthesized by *adsyn* alone.

Sound described by an *adsyn* control file can also be modified during re-synthesis. The signals *kamod*, *kfmod*, *ksmod* will modify the amplitude, frequency, and speed of contributing partials. These are multiplying factors, with *kfmod* modifying the frequency and *ksmod* modifying the *speed* with which the

millisecond breakpoint line-segments are traversed. Thus .7, 1.5, and 2 will give rise to a softer sound, a perfect fifth higher, but only half as long. The values 1,1,1 will leave the sound unmodified. Each of these inputs can be a control signal.

## Examples

Here is an example of the adsyn opcode. It uses the file *adsyn.csd* [examples/adsyn.csd], and *kickroll.het* [examples/kickroll.het]. The file “kickroll.het” was created by using the *hetro* utility with the audio file *kickroll.wav* [examples/kickroll.wav].

### Example 44. Example of the adsyn opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# adsynt

adsynt — Performs additive synthesis with an arbitrary number of partials, not necessarily harmonic.

## Description

Performs additive synthesis with an arbitrary number of partials, not necessarily harmonic.

## Syntax

```
ares adsynt kamp, kcps, iwnf, ifreqfn, iampfn, icnt [, iphs]
```

## Initialization

*iwnf* -- table containing a waveform, usually a sine. Table values are not interpolated for performance reasons, so larger tables provide better quality.

*ifreqfn* -- table containing frequency values for each partial. *ifreqfn* may contain beginning frequency values for each partial, but is usually used for generating parameters at runtime with *tablew*. Frequencies must be relative to *kcps*. Size must be at least *icnt*.

*iampfn* -- table containing amplitude values for each partial. *iampfn* may contain beginning amplitude values for each partial, but is usually used for generating parameters at runtime with *tablew*. Amplitudes must be relative to *kamp*. Size must be at least *icnt*.

*icnt* -- number of partials to be generated

*iphs* -- initial phase of each oscillator, if *iphs* = -1, initialization is skipped. If *iphs* > 1, all phases will be initialized with a random value.

## Performance

*kamp* -- amplitude of note

*kcps* -- base frequency of note. Partial frequencies will be relative to *kcps*.

Frequency and amplitude of each partial is given in the two tables provided. The purpose of this opcode is to have an instrument generate synthesis parameters at k-rate and write them to global parameter tables with the *tablew* opcode.

## Examples

Here is an example of the adsynt opcode. It uses the file *adsynt.csd* [examples/adsynt.csd]. These two instruments perform additive synthesis. The output of each sounds like a Tibetan bowl. The first one is static, as parameters are only generated at init-time. In the second one, parameters are continuously changed.

### Example 45. Example of the adsynt opcode.

## adsynt2

adsynt2 — Performs additive synthesis with an arbitrary number of partials -not necessarily harmonic- with interpolation.

## Description

Performs additive synthesis with an arbitrary number of partials, not necessarily harmonic. (see *adsynt* for detailed manual)

## Syntax

```
ar adsynt2 kamp, kcps, iwfn, ifreqfn, iampfn, icnt [, iphs]
```

## Initialization

*iwfn* -- table containing a waveform, usually a sine. Table values are not interpolated for performance reasons, so larger tables provide better quality.

*ifreqfn* -- table containing frequency values for each partial. *ifreqfn* may contain beginning frequency values for each partial, but is usually used for generating parameters at runtime with *tablew*. Frequencies must be relative to *kcps*. Size must be at least *icnt*.

*iampfn* -- table containing amplitude values for each partial. *iampfn* may contain beginning amplitude values for each partial, but is usually used for generating parameters at runtime with *tablew*. Amplitudes must be relative to *kamp*. Size must be at least *icnt*.

*icnt* -- number of partials to be generated

*iphs* -- initial phase of each oscillator, if *iphs* = -1, initialization is skipped. If *iphs* > 1, all phases will be initialized with a random value.

## Performance

*kamp* -- amplitude of note

*kcps* -- base frequency of note. Partial frequencies will be relative to *kcps*.

Frequency and amplitude of each partial is given in the two tables provided. The purpose of this opcode is to have an instrument generate synthesis parameters at k-rate and write them to global parameter tables with the *tablew* opcode.

*adsynt2* is identical to *adsynt* (by Peter Neubäcker), except it provides linear interpolation for amplitude envelopes of each partial. It is a bit slower than *adsynt*, but interpolation highly improves sound quality in fast amplitude envelope transients when *kr* < *sr* (i.e. when *ksmps* > 1). No interpolation is provided for pitch envelopes, since in this case sound quality degradation is not so evident even with high values of *ksmps*. It is not recommended when *kr* = *sr*, in this case *adsynt* is better (since it is faster).

## Examples

Here is an example of the *adsynt2* opcode. It uses the file *adsynt2.csd* [examples/adsynt2.csd]. These two instruments perform additive synthesis. The output of each sounds like a Tibetan bowl. The first one

is static, as parameters are only generated at init-time. In the second one, parameters are continuously changed.

# aftouch

aftouch — Get the current after-touch value for this channel.

## Description

Get the current after-touch value for this channel.

## Syntax

```
kaft aftouch [imin] [, imax]
```

## Initialization

*imin* (optional, default=0) -- minimum limit on values obtained.

*imax* (optional, default=127) -- maximum limit on values obtained.

## Performance

Get the current after-touch value for this channel.

## Examples

Here is an example of the aftouch opcode. It uses the file *aftouch.csd* [examples/aftouch.csd].

### Example 47. Example of the aftouch opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# alpass

alpass — Reverberates an input signal with a flat frequency response.

## Description

Reverberates an input signal with a flat frequency response.

## Syntax

```
ares alpass asig, xrvt, ilpt [, iskip] [, insmps]
```

## Initialization

*ilpt* -- loop time in seconds, which determines the “echo density” of the reverberation. This in turn characterizes the “color” of the filter whose frequency response curve will contain  $ilpt * sr/2$  peaks spaced evenly between 0 and  $sr/2$  (the Nyquist frequency). Loop time can be as large as available memory will permit. The space required for an *n* second loop is  $4n*sr$  bytes. The delay space is allocated and returned as in *delay*.

*iskip* (optional, default=0) -- initial disposition of delay-loop data space (cf. *reson*). The default value is 0.

*insmps* (optional, default=0) -- delay amount, as a number of samples.

## Performance

*xrvt* -- the reverberation time (defined as the time in seconds for a signal to decay to 1/1000, or 60dB down from its original amplitude).

This filter reiterates the input with an echo density determined by loop time *ilpt*. The attenuation rate is independent and is determined by *xrvt*, the reverberation time (defined as the time in seconds for a signal to decay to 1/1000, or 60dB down from its original amplitude). Output will begin to appear immediately.

## Examples

Here is an example of the alpass opcode. It uses the file *alpass.csd* [examples/alpass.csd].

### Example 48. Example of the alpass opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# alwayson

alwayson — Activates the indicated instrument in the orchestra header, without need for an i statement.

## Description

Activates the indicated instrument in the orchestra header, without need for an i statement. Instruments must be activated in the same order as they are defined.

The alwayson opcode is designed to simplify the definition of re-usable orchestras with signal processing or effects chains and networks.

## Syntax

```
alwayson Tinstrument [p4, ..., pn]
```

## Initialization

*Tinstrument* -- String name of the instrument definition to be turned on.

[*p4*, ..., *pn*] -- Optional pfields to be passed to the instrument, in the same order and type as if this were an i statement.

When the instrument is activated, p1 is the insno, p2 is 0, and p3 is -1. Pfields from p4 on may optionally be sent to the instrument.

## Examples

Here is an example of the alwayson opcode. It uses the file *alwayson.csd* [examples/alwayson.csd].

# ampdb

ampdb — Returns the amplitude equivalent of the decibel value x.

## Description

Returns the amplitude equivalent of the decibel value x. Thus:

- 60 dB = 1000
- 66 dB = 1995.262
- 72 dB = 3891.07
- 78 dB = 7943.279
- 84 dB = 15848.926
- 90 dB = 31622.764

## Syntax

```
ampdb(x)  (no rate restriction)
```

## Examples

Here is an example of the ampdb opcode. It uses the file *ampdb.csd* [examples/ampdb.csd].

### Example 50. Example of the ampdb opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# ampmidi

ampmidi — Get the velocity of the current MIDI event.

## Description

Get the velocity of the current MIDI event.

## Syntax

```
iamp ampmidi iscal [, ifn]
```

## Initialization

*iscal* -- i-time scaling factor

*ifn* (optional, default=0) -- function table number of a normalized translation table, by which the incoming value is first interpreted. The default value is 0, denoting no translation.

## Performance

Get the velocity of the current MIDI event, optionally pass it through a normalized translation table, and return an amplitude value in the range 0 - *iscal*.

## Examples

Here is an example of the ampmidi opcode. It uses the file *ampmidi.csd* [examples/ampmidi.csd].

### Example 52. Example of the ampmidi opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# ampmidid

ampmidid — Musically map MIDI velocity to peak amplitude within a specified dynamic range in decibels.

## Description

Musically map MIDI velocity to peak amplitude within a specified dynamic range in decibels.

## Syntax

```
iamplitude ampmidid ivedocity, idecibels
```

```
kamplitude ampmidid kvelocity, idecibels
```

## Initialization

*iamplitude* -- Amplitude.

*ivedocity* -- MIDI velocity number, ranging from 0 through 127.

*idecibels* -- Desired dynamic range in decibels.

## Performance

*kamplitude* -- Amplitude.

*kvelocity* -- MIDI velocity number, ranging from 0 through 127.

Musically map MIDI velocity to peak amplitude within a specified dynamic range in decibels:  $a = (m * v + b) ^ 2$ , where  $a$  = amplitude,  $v$  = MIDI velocity,  $r = 10 ^ (R / 20)$ ,  $b = 127 / (126 * \sqrt{r}) - 1 / 126$ ,  $m = (1 - b) / 127$ , and  $R$  = specified dynamic range in decibels. See Roger Dannenberg, "The Interpretation of MIDI Velocity," in Georg Essl and Ichiro Fujinaga (Eds.), Proceedings of the 2006 International Computer Music Conference, November 6-11, 2006 (San Francisco: The International Computer Music Association), pp. 193-196.

## Examples

Here is an example of the ampmidid opcode. It uses the file *ampmidid.csd* [examples/ampmidid.csd].

# areson

**areson** — A notch filter whose transfer functions are the complements of the reson opcode.

## Description

A notch filter whose transfer functions are the complements of the reson opcode.

## Syntax

```
ares areson asig, kcf, kbw [, iscl] [, iskip]  
  
ares areson asig, acf, kbw [, iscl] [, iskip]  
  
ares areson asig, kcf, abw [, iscl] [, iskip]  
  
ares areson asig, acf, abw [, iscl] [, iskip]
```

## Initialization

*iscl* (optional, default=0) -- coded scaling factor for resonators. A value of 1 signifies a peak response factor of 1, i.e. all frequencies other than kcf/acf are attenuated in accordance with the (normalized) response curve. A value of 2 raises the response factor so that its overall RMS value equals 1. (This intended equalization of input and output power assumes all frequencies are physically present; hence it is most applicable to white noise.) A zero value signifies no scaling of the signal, leaving that to some later adjustment (see *balance*). The default value is 0.

*iskip* (optional, default=0) -- initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*ares* -- the output signal at audio rate.

*asig* -- the input signal at audio rate.

*kcf/acf* -- the center frequency of the filter, or frequency position of the peak response.

*kbw/abw* -- bandwidth of the filter (the Hz difference between the upper and lower half-power points).

**areson** is a filter whose transfer functions is the complement of *reson*. Thus *areson* is a notch filter whose transfer functions represents the “filtered out” aspects of their complements. However, power scaling is not normalized in *areson* but remains the true complement of the corresponding unit. Thus an audio signal, filtered by parallel matching *reson* and *areson* units, would under addition simply reconstruct the original spectrum.

This property is particularly useful for controlled mixing of different sources (see *lpreson*). Complex response curves such as those with multiple peaks can be obtained by using a bank of suitable filters in series. (The resultant response is the product of the component responses.) In such cases, the combined attenuation may result in a serious loss of signal power, but this can be regained by the use of *balance*.

## Warning

When used with *iscl* this opcode is not a notch filter but similar to *reson*.

## Examples

Here is an example of the areson opcode. It uses the file *areson.csd* [examples/areson.csd].

### Example 54. Example of the areson opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# aresonk

aresonk — A notch filter whose transfer functions are the complements of the reson opcode.

## Description

A notch filter whose transfer functions are the complements of the reson opcode.

## Syntax

```
kres aresonk ksig, kcf, kbw [, iscl] [, iskip]
```

## Initialization

*iscl* (optional, default=0) -- coded scaling factor for resonators. A value of 1 signifies a peak response factor of 1, i.e. all frequencies other than kcf are attenuated in accordance with the (normalized) response curve. A value of 2 raises the response factor so that its overall RMS value equals 1. (This intended equalization of input and output power assumes all frequencies are physically present; hence it is most applicable to white noise.) A zero value signifies no scaling of the signal, leaving that to some later adjustment (see *balance*). The default value is 0.

*iskip* (optional, default=0) -- initial disposition of internal data space. Since filtering incorporates a feed-back loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*kres* -- the output signal at control-rate.

*ksig* -- the input signal at control-rate.

*kcf* -- the center frequency of the filter, or frequency position of the peak response.

*kbw* -- bandwidth of the filter (the Hz difference between the upper and lower half-power points).

*aresonk* is a filter whose transfer functions is the complement of *resonk*. Thus *aresonk* is a notch filter whose transfer functions represents the “filtered out” aspects of their complements. However, power scaling is not normalized in *aresonk* but remains the true complement of the corresponding unit.

## Examples

Here is an example of the aresonk opcode. It uses the file *aresonk.csd* [examples/aresonk.csd].

### Example 55. Example of the aresonk opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# atone

atone — A hi-pass filter whose transfer functions are the complements of the *tone* opcode.

## Description

A hi-pass filter whose transfer functions are the complements of the *tone* opcode.

## Syntax

```
ares atone asig, khp [, iskip]
```

## Initialization

*iskip* (optional, default=0) -- initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*ares* -- the output signal at audio rate.

*asig* -- the input signal at audio rate.

*khp* -- the response curve's half-power point, in Hertz. Half power is defined as peak power / root 2.

*atone* is a filter whose transfer functions is the complement of *tone*. *atone* is thus a form of high-pass filter whose transfer functions represent the “filtered out” aspects of their complements. However, power scaling is not normalized in *atone* but remains the true complement of the corresponding unit. Thus an audio signal, filtered by parallel matching *tone* and *atone* units, would under addition simply reconstruct the original spectrum.

This property is particularly useful for controlled mixing of different sources (see *lpreson*). Complex response curves such as those with multiple peaks can be obtained by using a bank of suitable filters in series. (The resultant response is the product of the component responses.) In such cases, the combined attenuation may result in a serious loss of signal power, but this can be regained by the use of *balance*.

## Examples

Here is an example of the *atone* opcode. It uses the file *atone.csd* [examples/atone.csd].

### Example 56. Example of the *atone* opcode.

# atonex

atonex — Emulates a stack of filters using the atone opcode.

## Description

*atonex* is equivalent to a filter consisting of more layers of *atone* with the same arguments, serially connected. Using a stack of a larger number of filters allows a sharper cutoff. They are faster than using a larger number instances in a Csound orchestra of the old opcodes, because only one initialization and k-cycle are needed at time and the audio loop falls entirely inside the cache memory of processor.

## Syntax

```
ares atonex asig, khp [, inumlayer] [, iskip]  
  
ares atonex asig, ahp [, inumlayer] [, iskip]
```

## Initialization

*inumlayer* (optional) -- number of elements in the filter stack. Default value is 4.

*iskip* (optional, default=0) -- initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*asig* -- input signal

*khp/ahp* -- the response curve's half-power point. Half power is defined as peak power / root 2.

## Examples

Here is an example of the atonex opcode. It uses the file *atonex.csd* [examples/atonex.csd].

# ATSadd

ATSadd — uses the data from an ATS analysis file to perform additive synthesis.

## Description

*ATSadd* reads from an ATS analysis file and uses the data to perform additive synthesis using an internal array of interpolating oscillators.

## Syntax

```
ar ATSadd ktimepnt, kfmod, iatsfile, ifn, ipartial[], ipartialoffset, \
    ipartialincr, igatefn]
```

## Initialization

*iatsfile* – the ATS number (n in ats.n) or the name in quotes of the analysis file made using *ATS* [<http://www-ccrma.stanford.edu/~juan/ATS.html>].

*ifn* – table number of a stored function containing a sine wave for *ATSadd* and a cosine for *ATSaddnz* (see examples below for more info)

*ipartial[]* – number of partials that will be used in the resynthesis (the noise has a maximum of 25 bands)

*ipartialoffset* (optional) – is the first partial used (defaults to 0).

*ipartialincr* (optional) – sets an increment by which these synthesis opcodes counts up from *ipartialoffset* for ibins components in the re-synthesis (defaults to 1).

*igatefn* (optional) – is the number of a stored function which will be applied to the amplitudes of the analysis bins before resynthesis takes place. If *igatefn* is greater than 0 the amplitudes of each bin will be scaled by *igatefn* through a simple mapping process. First, the amplitudes of all of the bins in all of the frames in the entire analysis file are compared to determine the maximum amplitude value. This value is then used to create normalized amplitudes as indices into the stored function *igatefn*. The maximum amplitude will map to the last point in the function. An amplitude of 0 will map to the first point in the function. Values between 0 and 1 will map accordingly to points along the function table. See the examples below.

## Performance

*ktimepnt* – The time pointer in seconds used to index the ATS file. Used for *ATSadd* exactly the same as for *pvoc*.

*ATSadd* and *ATSaddnz* are based on *pvadd* by Richard Karpen and use files created by Juan Pampin's *ATS (Analysis - Transformation - Synthesis* [<http://www-ccrma.stanford.edu/~juan/ATS.html>]).

*kfmod* – A control-rate transposition factor: a value of 1 incurs no transposition, 1.5 transposes up a perfect fifth, and .5 down an octave. Used for *ATSadd* exactly the same as for *pvoc*.

*ATSadd* reads from an ATS analysis file and uses the data to perform additive synthesis using an internal array of interpolating oscillators. The user supplies the wave table (usually one period of a sine wave), and can choose which analysis partials will be used in the re-synthesis.

## Examples

```
ktme line 0, p3, 2.5
asig ATSadd ktime, 1, "clarinet.ats", 1, 20, 2
```

In the example above, *ipartial* is 20 and *ipartialoffset* is 2. This will synthesize the 3rd thru 22nd partials in the "clarinet.ats" analysis file. *kfmnod* is 1 so there will be no pitch transformation. Since the *ktimepnt* envelope moves from 0 to 2.5 over the duration of the note, the analysis file will be read from 0 to 2.5 seconds of the original duration of the analysis over the duration of the csound note, this way we can change the duration independent of the pitch.

## Examples

Here is a complete example of the ATSadd opcode. It uses the file *ATSadd.csd* [examples/ATSadd.csd].

### Example 59. Example of the ATSadd opcode.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac     ;;;RT audio out
;-iadc    ;;;uncomment -iadc for RT audio input is needed too
; For Non-realtime output leave only the line below:
;-o ATSadd.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1 ; "beats.ats" is created by atsa

ktme line 0, p3, 2
asig ATSadd ktime, 1, "beats.ats", 1, 20, 0, 2
        outs asig*3, asig*3 ;amplify

endin

</CsInstruments>
<CsScore>
;sine wave.
f 1 0 16384 10 1

i 1 0 2
e

</CsScore>
</CsoundSynthesizer>
```

In the above example we synthesize 20 partials as in example 1 except this time we're using a *ipartialoffset* of 0 and *ipartialincr* of 2, which means that we'll start from the first partial and synthesize 20 partials total, skipping every other one (ie. partial 1, 3, 5,...).

Here is another example of the ATSadd opcode. It uses the file *ATSadd-2.csd* [examples/ATSadd-2.csd].

### Example 60. Example 2 of the ATSadd opcode.

# ATSaddnz

ATSaddnz — uses the data from an ATS analysis file to perform noise resynthesis.

## Description

*ATSaddnz* reads from an ATS analysis file and uses the data to perform additive synthesis using a modified randi function.

## Syntax

```
ar ATSaddnz ktimepnt, iatsfile, ibands[, ibandoffset, ibandincr]
```

## Initialization

*iatsfile* – the ATS number (n in ats.n) or the name in quotes of the analysis file made using *ATS* [<http://www-ccrma.stanford.edu/~juan/ATS.html>].

*ibands* – number of noise bands that will be used in the resynthesis (the noise has a maximum of 25 bands)

*ibandoffset* (optional) – is the first noise band used (defaults to 0).

*ibandincr* (optional) – sets an increment by which these synthesis opcodes counts up from *ibandoffset* for ibins components in the re-synthesis (defaults to 1).

## Performance

*ktimepnt* – The time pointer in seconds used to index the ATS file. Used for *ATSaddnz* exactly the same as for *pvoc* and *ATSadd*.

*ATSaddnz* and *ATSadd* are based on *pvadd* by Richard Karpen and use files created by Juan Pampin's *ATS (Analysis - Transformation - Synthesis* [<http://www-ccrma.stanford.edu/~juan/ATS.html>]).

*ATSaddnz* also reads from an ATS file but it resynthesizes the noise from noise energy data contained in the ATS file. It uses a modified randi function to create band limited noise and modulates that with a cosine wave, to synthesize a user specified selection of frequency bands. Modulating the noise is required to put the band limited noise in the correct place in the frequency spectrum.

## Examples

```
ktime line 0, p3, 2.5
asig ATSaddnz ktime, "clarinet.ats", 25
```

In the example above we're synthesizing all 25 noise bands from the data contained in the ATS analysis file called "clarinet.ats".

## Examples

Here is a complete example of the *ATSaddnz* opcode. It uses the file *ATSaddnz.csd* [examples/ATSaddnz.csd].

### Example 61. Example of the ATSaddnz opcode.

```
<CsoundSynthesizer>

# ATSBufread

ATSBufread — reads data from an ATS data file and stores it in an internal data table of frequency, amplitude pairs.

## Description

*ATSBufread* reads data from an ATS data file and stores it in an internal data table of frequency, amplitude pairs.

## Syntax

```
ATSBufread ktimepnt, kfmod, iatsfile, ipartial[], ipartialoffset, \
ipartialincr]
```

## Initialization

*iatsfile* – the ATS number (n in ats.n) or the name in quotes of the analysis file made using ATS [<http://www-ccrma.stanford.edu/~juan/ATS.html>].

*ipartial[]* – number of partials that will be used in the resynthesis (the noise has a maximum of 25 bands)

*ipartialoffset* (optional) – is the first partial used (defaults to 0).

*ipartialincr* (optional) – sets an increment by which these synthesis opcodes counts up from *ipartialoffset* for ibins components in the re-synthesis (defaults to 1).

## Performance

*ktimepnt* – The time pointer in seconds used to index the ATS file. Used for *ATSBufread* exactly the same as for *pvc*.

*kfmod* – an input for performing pitch transposition or frequency modulation on all of the synthesized partials, if no fm or pitch change is desired then use a 1 for this value.

*ATSBufread* is based on *pbufread* by Richard Karpen. *ATScross*, *ATSinspread* and *ATSpartialtap* are all dependent on *ATSBufread* just as *pvcross* and *pvintrp* are on *pbufread*. *ATSBufread* reads data from an ATS data file and stores it in an internal data table of frequency, amplitude pairs. The data stored by an *ATSBufread* can only be accessed by other unit generators, and therefore, due to the architecture of Csound, an *ATSBufread* must come before (but not necessarily directly) any dependent unit generator. Besides the fact that *ATSBufread* doesn't output any data directly, it works almost exactly as *ATSadd*. The ugen uses a time pointer (*ktimepnt*) to index the data in time, *ipartial[]*, *ipartialoffset* and *ipartialincr* to select which partials to store in the table and *kfmod* to scale partials in frequency.

## Examples

Here is an example of the *ATSBufread* opcode. It uses the file *ATSBufread.csd* [examples/ATSBufread.csd].

# ATScross

ATScross — perform cross synthesis from ATS analysis files.

## Description

*ATScross* uses data from an ATS analysis file and data from an *ATSbufread* to perform cross synthesis.

## Syntax

```
ar ATScross ktimepnt, kfmod, iatsfile, ifn, kmylev, kbuflev, ipartials \
[, ipartialoffset, ipartialincr]
```

## Initialization

*iatsfile* – integer or character-string denoting a control-file derived from ATS analysis of an audio signal. An integer denotes the suffix of a file ATS.m; a character-string (in double quotes) gives a filename, optionally a full pathname. If not full-path, the file is sought first in the current directory, then in the one given by the environment variable SADIR (if defined).

*ifn* – table number of a stored function containing a sine wave.

*ipartials* – number of partials that will be used in the resynthesis

*ipartialoffset* (optional) – is the first partial used (defaults to 0).

*ipartialincr* (optional) – sets an increment by which these synthesis opcodes counts up from *ipartialoffset* for ibins components in the re-synthesis (defaults to 1).

## Performance

*ktimepnt* – The time pointer in seconds used to index the ATS file. Used for *ATScross* exactly the same as for *pvoc*.

*kfmod* – an input for performing pitch transposition or frequency modulation on all of the synthesized partials, if no fm or pitch change is desired then use a 1 for this value.

*kmylev* - scales the *ATScross* component of the frequency spectrum applied to the partials from the ATS file indicated by the *ATScross* opcode. The frequency spectrum information comes from the *ATScross* ATS file. A value of 1 (and 0 for *kbuflev*) gives the same results as *ATSadd*.

*kbuflev* - scales the *ATSbufread* component of the frequency spectrum applied to the partials from the ATS file indicated by the *ATScross* opcode. The frequency spectrum information comes from the *ATSbufread* ATS file. A value of 1 (and 0 for *kmylev*) results in partials that have frequency information from the ATS file given by the *ATScross*, but amplitudes imposed by data from the ATS file given by *ATSbufread*.

*ATScross* uses data from an ATS analysis file (indicated by *iatsfile*) and data from an *ATSbufread* to perform cross synthesis. *ATScross* uses *ktimepnt*, *kfmod*, *ipartials*, *ipartialoffset* and *ipartialincr* just like *ATSadd*. *ATScross* synthesizes a sine-wave for each partial selected by the user and uses the frequency of that partial (after scaling in frequency by *kfmod*) to index the table created by *ATSbufread*. Interpolation is used to get in-between values. *ATScross* uses the sum of the amplitude data from its ATS file (scaled by *kmylev*) and the amplitude data gained from an *ATSbufread* (scaled by *kbuflev*) to scale the

amplitude of each partial it synthesizes. Setting *kmylev* to one and *kbuflev* to zero will make *ATScross* act exactly like *ATSadd*. Setting *kmylev* to zero and *kbuflev* to one will produce a sound that has all the partials selected by the *ATScross* ugen, but with amplitudes taken from an *ATBufread*. The time pointers of the *ATBufread* and *ATScross* do not need to be the same.

## Examples

Here is an example of the *ATScross* opcode. It uses the file *ATScross.csd* [examples/ATScross.csd].

### Example 64. Example of the *ATScross* opcode.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac      ;;;RT audio out
;-iadc      ;;;uncomment -iadc for RT audio input is needed too
; For Non-realtime output leave only the line below:
;-o ATScross.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1 ; "beats.ats" and "fox.ats" are created by atsa

ktime line 0, p3, 4
ktime2 line 0, p3, 4
kline expseg 0.001, .3, 1, p3-.3, 1
kline2 expseg 0.001, p3, 3
        ATBufread ktime2, 1, "fox.ats", 20
aout ATScross   ktime, 2, "beats.ats", 1, kline, 0.001 * (4 - kline2), 180

endin

</CsInstruments>
<CsScore>
; sine wave.
f 1 0 16384 10 1

i 1 0 4
e
</CsScore>
</CsoundSynthesizer>
```

This example performs cross synthesis using two ATS-files, "fox.ats" and "beats.ats". The result of this will be a sound that starts out with the shape (in frequency) of fox.ats, and ends with the shape of beats.ats. All the sine-wave frequencies come from beats.ats. The *kbuflev* value is scaled because the energy produced by applying fox.ats's frequency spectrum to beats.ats's partials is very large. Notice also that the time pointers of the *ATBufread* (fox.ats) and *ATScross* (beats.ats) need not have the same value, this way you can read through the two ATS files at different rates.

# ATSinfo

ATSinfo — reads data out of the header of an ATS file.

## Description

*atsinfo* reads data out of the header of an ATS file.

## Syntax

```
idata ATSinfo iatsfile, ilocation
```

## Initialization

*iatsfile* – the ATS number (n in ats.n) or the name in quotes of the analysis file made using *ATS* [<http://www-ccrma.stanford.edu/~juan/ATS.html>].

*ilocation* – indicates which location in the header file to return. The data in the header gives information about the data contained in the rest of the ATS file. The possible values for *ilocation* are given in the following list:

- 0 - Sample rate (Hz)
- 1 - Frame Size (samples)
- 2 - Window Size (samples)
- 3 - Number of Partials
- 4 - Number of Frames
- 5 - Maximum Amplitude
- 6 - Maximum Frequency (Hz)
- 7 - Duration (seconds)
- 8 - ATS file Type

## Performance

Macros can really improve the legibility of your csound code, I've provided my Macro Definitions below:

```
#define ATS_SAMP_RATE #0#
#define ATS_FRAME_SZ #1#
#define ATS_WIN_SZ #2#
#define ATS_N_PARTIALS #3#
#define ATS_N_FRAMES #4#
#define ATS_AMP_MAX #5#
#define ATS_FREQ_MAX #6#
#define ATS_DUR #7#
#define ATS_TYPE #8#
```

*ATSinfo* can be useful for writing generic instruments that will work with many ATS files, even if they

have different lengths and different numbers of partials etc. Example 2 is a simple application of this.

## Examples

Here is an example of the ATSinfo opcode. It uses the file *ATSinfo.csd* [examples/ATSinfo.csd].

### Example 65. Example of the ATSinfo opcode.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac      ;;;RT audio out
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2

instr 1 ; "fox.ats" is created by atsa
    inum_partials ATSinfo "fox.ats", 3
        print inum_partials

    endin

</CsInstruments>
<CsScore>
i 1 0 0
e

</CsScore>
</CsoundSynthesizer>
```

In the example above we use *ATSinfo* to retrieve the number of partials in the ATS file

## Other examples

1.

```
imax_freq     ATSinfo "cl.ats", $ATS_FREQ_MAX
```

In the example above we get the maximum frequency value from the ATS file "cl.ats" and store it in imax\_freq. We use the Csound Macro (defined above) \$ATS\_FREQ\_MAX, which is equivalent to the number 6.

2.

```
i_npartials   ATSinfo p4, $ATS_N_PARTIALS
i_dur         ATSinfo p4, $ATS_DUR
ktimepnt     line 0, p3, i_dur
aout          ATSadd ktimepnt, 1, p4, 1, i_npartials
```

In the example above we use *ATSinfo* to retrieve the duration and number of partials in the ATS file indicated by p4. With this info we synthesize the partials using *atsadd*. Since the duration and number of partials are not "hard-coded" we can use this code with any ATS file.

Here is another example of the ATSinfo opcode. It uses the file *ATSinfo-2.csd* [examples/ATSinfo-2.csd].

#### **Example 66. Example 2 of the ATSinfo opcode.**

2004

# ATSinterpread

*ATSinterpread* — allows a user to determine the frequency envelope of any *ATSBufread*.

## Description

*ATSinterpread* allows a user to determine the frequency envelope of any *ATSBufread*.

## Syntax

```
kamp ATSinterpread kfreq
```

## Performance

*kfreq* - a frequency value (given in Hertz) used by *ATSinterpread* as an index into the table produced by an *ATSBufread*.

*ATSinterpread* takes a frequency value (*kfreq* in Hz). This frequency is used to index the data of an *ATSBufread*. The return value is an amplitude gained from the *ATSBufread* after interpolation. *ATSinterpread* allows a user to determine the frequency envelope of any *ATSBufread*. This data could be useful for a number of reasons, one might be performing cross synthesis of data from an ATS file and non ATS data.

## Examples

Here is an example of the *ATSinterpread* opcode. It uses the file *ATSinterpread.csd* [examples/*ATSinterpread.csd*].

### Example 67. Example of the *ATSinterpread* opcode.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac    ;;;RT audio out
;-iadc   ;;;uncomment -iadc for RT audio input is needed too
; For Non-realtime output leave only the line below:
;-o ATSinterpread.wav -W ;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1 ; "beats.ats" is created by atsa
ktime line 0, p3, 1.8
        ATSBufread ktime, 1, "beats.ats", 42
kamp ATSinterpread p4
aosc oscili kamp, p4, 1
        outs aosc * 25, aosc *25

endin

</CsInstruments>
<CsScore>
; sine wave.
```

```
f 1 0 16384 10 1
i 1 0 2 100
e

</CsScore>
</CsoundSynthesizer>
```

This example shows how to use *ATSinterpread*. Here a frequency is given by the score (p4) and this frequency is given to an *ATSinterpread* (with a corresponding *ATSBufread*). The *ATSinterpread* uses this frequency to output a corresponding amplitude value, based on the atsfile given by the *ATSBufread* (beats.ats in this case). We then use that amplitude to scale a sine-wave that is synthesized with the same frequency (p4). You could extend this to include multiple sine-waves. This way you could synthesize any reasonable frequency (within the low and high frequencies of the indicated ATS file), and maintain the shape (in frequency) of the indicated atsfile (given by the *ATSBufread*).

# ATSread

ATSread — reads data from an ATS file.

## Description

*ATSread* returns the amplitude (*kamp*) and frequency (*kfreq*) information of a user specified partial contained in the ATS analysis file at the time indicated by the time pointer *ktimepnt*.

## Syntax

```
kfreq, kamp ATSread ktimepnt, iatsfile, ipartial
```

## Initialization

*iatsfile* – the ATS number (n in ats.n) or the name in quotes of the analysis file made using *ATS* [<http://www-ccrma.stanford.edu/~juan/ATS.html>].

*ipartial* – the number of the analysis partial to return the frequency in Hz and amplitude.

## Performance

*kfreq, kamp* - outputs of the *ATSread* unit. These values represent the frequency and amplitude of a specific partial selected by the user using *ipartial*. The partials' informations are derived from an ATS analysis. *ATSread* linearly interpolates the frequency and amplitude between frames in the ATS analysis file at k-rate. The output is dependent on the data in the analysis file and the pointer *ktimepnt*.

*ktimepnt* – The time pointer in seconds used to index the ATS file. Used for *ATSread* exactly the same as for *pvoc* and *ATSadd*.

## Examples

Here is an example of the *ATSread* opcode. It uses the file *ATSread.csd* [examples/ATSread.csd].

### Example 68. Example of the *ATSread* opcode.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac    ;;;RT audio out
;-iadc   ;;;uncomment -iadc if RT audio input is needed too
; For Non-realtime ouput leave only the line below:
; -o ATSread.wav -W ;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1 ; "beats.ats" is created by atsa
ktime line 0, p3, 2
kfreq, kamp ATSread ktime, "beats.ats", 100
```

```
aout oscili 0.8, kfreq, 1
    outs aout, aout

endin

</CsInstruments>
<CsScore>
;sine wave.
f 1 0 16384 10 1

i 1 0 2
e

</CsScore>
</CsoundSynthesizer>
```

Here we're using *ATSread* to get the 100th partial's frequency and amplitude data out of the 'beats.ats' ATS analysis file. We're using that data to drive an oscillator, but we could use it for anything else that can take a k-rate input, like the bandwidth and resonance of a filter etc.

Here is another example of the *ATSread* opcode. It uses the file *ATSread-2.csd* [examples/ATS-read-2.csd].

### Example 69. Example 2 of the *ATSread* opcode.

# ATsreadnz

**ATSreadnz** — reads data from an ATS file.

## Description

*ATStradnz* returns the energy (*kenergy*) of a user specified noise band (1-25 bands) at the time indicated by the time pointer *ktimepnt*.

## Syntax

kenergy **ATSreadnz** ktimepnt, iatsfile, iband

## Initialization

*iatsfile* – the ATS number (n in ats.n) or the name in quotes of the analysis file made using ATS [<http://www-ccrma.stanford.edu/~juan/ATS.html>].

*iband* – the number of the noise band to return the energy data.

## Performance

*kenergy* outputs the linearly interpolated energy of the noise band indicated in *iband*. The output is dependent on the data in the analysis file and the *ktimepnt*.

*ktimepnt* – The time pointer in seconds used to index the ATS file. Used for *ATSreadnz* exactly the same as for *pvoc* and *ATSadz*.

*ATSaddnz* reads from an ATS file and resynthesizes the noise from noise energy data contained in the ATS file. It uses a modified randi function to create band limited noise and modulates that with a user supplied wave table (one period of a cosine wave), to synthesize a user specified selection of frequency bands. Modulating the noise is required to put the band limited noise in the correct place in the frequency spectrum.

An ATS analysis differs from a pvanal in that ATS tracks the partials and computes the noise energy of the sound being analyzed. For more info about ATS analysis read Juan Pampin's description on the the *ATS* [<http://www-ccrma.stanford.edu/~juan/ATS.html>] web-page.

## Examples

```
ktime    line      2.5, p3, 0  
kenergy  ATSreadnz ktime, "clarinet.ats", 5
```

Here we are extracting the noise energy from band 5 in the 'clarinet.ats' ATS analysis file. We're actually reading backwards from 2.5 seconds to the beginning of the analysis file. We could use this to synthesize noise like this:

```
anoise  randi      sqrt(kenergy), 55
aout    oscili     40000000000000000000000000000000, 455, 2
aout    =           aout * anoise
```

Function table 2 used in the oscillator is a cosine, which is needed to shift the band limited noise into the correct place in the frequency spectrum. The *randi* function creates a band of noise centered about 0 Hz that has a bandwidth of about 110 Hz; multiplying it by a cosine will shift it to be centered at 455 Hz, which is the center frequency of the 5th critical noise band. This is only an example, for synthesizing the noise you'd be better off just using *ATSaddnz* unless you want to use your own noise synthesis algorithm. Maybe you could use the noise energy for something else like applying a small amount of jitter to specific partials or for controlling something totally unrelated to the source sound?

## Examples

Here is another example of the *ATSreadnz* opcode. It uses the file *ATSreadnz.csd* [examples/ATSreadnz.csd].

### Example 70. Another example of the *ATSreadnz* opcode.

# ATSpartialtap

ATSpartialtap — returns a frequency, amplitude pair from an *ATSbufread* opcode.

## Description

*ATSpartialtap* takes a partial number and returns a frequency, amplitude pair. The frequency and amplitude data comes from an *ATSbufread* opcode.

## Syntax

```
kfrq, kamp ATSpartialtap ipartialnum
```

## Initialization

*ipartialnum* - indicates the partial that the *ATSpartialtap* opcode should read from an *ATSbufread*.

## Performance

*kfrq* - returns the frequency value for the requested partial.

*kamp* - returns the amplitude value for the requested partial.

*ATSpartialtap* takes a partial number and returns a frequency, amplitude pair. The frequency and amplitude data comes from an *ATSbufread* opcode. This is more restricted version of *ATSread*, since each *ATSread* opcode has its own independent time pointer, and *ATSpartialtap* is restricted to the data given by an *ATSbufread*. Its simplicity is its attractive feature.

## Examples

Here is an example of the *ATSpartialtap* opcode. It uses the file *ATSpartialtap.csd* [examples/ATSpartialtap.csd].

### Example 71. Example of the ATSpartialtap opcode.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac    ;;;RT audio out
;-iadc   ;;;uncomment -iadc for RT audio input is needed too
; For Non-realtime output leave only the line below:
;-o ATSpartialtap.wav -W ;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1 ; "beats.ats" is created by atsa
ktime line 0, p3, 2
        ATSbufread ktime, 1, "beats.ats", 30
kfreq1, kam1 ATSpartialtap 5
```

```
kfreq2, kam2 ATSpartialtap 20
kfreq3, kam3 ATSpartialtap 30

aout1 oscil kam1, kfreq1, 1
aout2 oscil kam2, kfreq2, 1
aout3 oscil kam3, kfreq3, 1
aout = (aout1+aout2+aout3)*10 ; amplify some more
      outs aout, aout

endin

</CsInstruments>
<CsScore>
; sine wave.
f 1 0 16384 10 1
i 1 0 2
e

</CsScore>
</CsoundSynthesizer>
```

This example here uses an *ATSpartialtap*, and an *ATSpbufread* to read partials 5, 20 and 30 from 'beats.ats'. These amplitudes and frequencies could be used to re-synthesize those partials, or something all together different.

# ATSSinnoi

ATSSinnoi — uses the data from an ATS analysis file to perform resynthesis.

## Description

*ATSSinnoi* reads data from an ATS data file and uses the information to synthesize sines and noise together.

## Syntax

```
ar ATSSinnoi ktimepnt, ksinlev, knzlev, kfmod, iatsfile, ipartial \  
[ , ipartialoffset, ipartialincr]
```

## Initialization

*iatsfile* – the ATS number (n in ats.n) or the name in quotes of the analysis file made using ATS [<http://www-ccrma.stanford.edu/~juan/ATS.html>].

*ipartial* – number of partials that will be used in the resynthesis (the noise has a maximum of 25 bands)

*ipartialoffset* (optional) – is the first partial used (defaults to 0).

*ipartialincr* (optional) – sets an increment by which these synthesis opcodes counts up from *ipartialoffset* for ibins components in the re-synthesis (defaults to 1).

## Performance

*ktimepnt* – The time pointer in seconds used to index the ATS file. Used for *ATSSinnoi* exactly the same as for *pvc*.

*ksinlev* - controls the level of the sines in the *ATSSinnoi* ugen. A value of 1 gives full volume sinewaves.

*knzlev* - controls the level of the noise components in the *ATSSinnoi* ugen. A value of 1 gives full volume noise.

*kfmod* – an input for performing pitch transposition or frequency modulation on all of the synthesized partials, if no fm or pitch change is desired then use a 1 for this value.

*ATSSinnoi* reads data from an ATS data file and uses the information to synthesize sines and noise together. The noise energy for each band is distributed equally among each partial that falls in that band. Each partial is then synthesized, along with that partial's noise component. Each noise component is then modulated by the corresponding partial to be put in the correct place in the frequency spectrum. The level of the noise and the partials are individually controllable. See the ATS [<http://www-ccrma.stanford.edu/~juan/ATS.html>] webpage for more info about the sinnoi synthesis. An ATS analysis differs from a pvanal in that ATS tracks the partials and computes the noise energy of the sound being analyzed. For more info about ATS analysis read Juan Pampin's description on the the ATS [<http://www-ccrma.stanford.edu/~juan/ATS.html>] web-page.

## Examples

```
ktime    line      0, p3, 2.5  
asig     ATSSinnoi  ktime, 1, 1, 1, "beats.ats", 42
```

Here we synthesize both the noise and the sinewaves (all 42 partials) contained in "beats.ats" together. The relative volumes of the noise and the partials are unaltered (each set to 1).

Here is another example of the ATSSinnoi opcode. It uses the file *ATSSinnoi.csd* [examples/ATSSinnoi.csd].

### Example 72. Example of the ATSSinnoi opcode.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac      ;;;RT audio out
;-iadc     ;;;uncomment -iadc if RT audio input is needed too
; For Non-realtime output leave only the line below:
;-o ATSSinnoi.wav -W ;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1 ; "beats.ats" is created by atsa

ktime line 0, p3, 2
knzfade expn 0.001, p3, 2
aout ATSSinnoi          ktime, 1, knzfade, 1, "beats.ats", 150
           outs aout*2, aout*2      ;amplify some more
endin

</CsInstruments>
<CsScore>

i 1 0 2
e

</CsScore>
</CsoundSynthesizer>
```

This example here is like the other example except that we use an envelope to control *knzlev* (the noise level). The result of this will be the "beats.wav" sound that has its noise component fade in over the duration of the note.

Here is another example of the ATSSinnoi opcode. It uses the file *ATSSinnoi-2.csd* [examples/ATSSinnoi-2.csd].

# babo

babo — A physical model reverberator.

## Description

*babo* stands for *ball-within-the-box*. It is a physical model reverberator based on the paper by Davide Rocchesso "The Ball within the Box: a sound-processing metaphor", Computer Music Journal, Vol 19, N.4, pp.45-47, Winter 1995.

The resonator geometry can be defined, along with some response characteristics, the position of the listener within the resonator, and the position of the sound source.

## Syntax

```
a1, a2 babo asig, ksrcx, ksrcy, ksrcz, irx, iry, irz [, idiff] [, ifno]
```

## Initialization

*irx, iry, irz* -- the coordinates of the geometry of the resonator (length of the edges in meters)

*idiff* -- is the coefficient of diffusion at the walls, which regulates the amount of diffusion (0-1, where 0 = no diffusion, 1 = maximum diffusion - default: 1)

*ifno* -- expert values function: a function number that holds all the additional parameters of the resonator. This is typically a GEN2--type function used in non-rescaling mode. They are as follows:

- *decay* -- main decay of the resonator (default: 0.99)
- *hydecay* -- high frequency decay of the resonator (default: 0.1)
- *rcvx, rcvy, rcvz* -- the coordinates of the position of the receiver (the listener) (in meters; 0,0,0 is the resonator center)
- *rdistance* -- the distance in meters between the two pickups (your ears, for example - default: 0.3)
- *direct* -- the attenuation of the direct signal (0-1, default: 0.5)
- *early\_diff* -- the attenuation coefficient of the early reflections (0-1, default: 0.8)

## Performance

*asig* -- the input signal

*ksrcx, ksrcy, ksrcz* -- the virtual coordinates of the source of sound (the input signal). These are allowed to move at k-rate and provide all the necessary variations in terms of response of the resonator.

## Examples

Here is a simple example of the *babo* opcode. It uses the file *babo.csd* [examples/babo.csd], and *beats.wav* [examples/beats.wav].

### Example 74. A simple example of the babo opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# balance

`balance` — Adjust one audio signal according to the values of another.

## Description

The rms power of `asig` can be interrogated, set, or adjusted to match that of a comparator signal.

## Syntax

```
ares balance asig, acomp [, ihp] [, iskip]
```

## Initialization

*ihp* (optional) -- half-power point (in Hz) of a special internal low-pass filter. The default value is 10.

*iskip* (optional, default=0) -- initial disposition of internal data space (see *reson*). The default value is 0.

## Performance

*asig* -- input audio signal

*acomp* -- the comparator signal

*balance* outputs a version of *asig*, amplitude-modified so that its rms power is equal to that of a comparator signal *acomp*. Thus a signal that has suffered loss of power (eg., in passing through a filter bank) can be restored by matching it with, for instance, its own source. It should be noted that *gain* and *balance* provide amplitude modification only - output signals are not altered in any other respect.

## Examples

Here is an example of the *balance* opcode. It uses the file *balance.csd* [examples/balance.csd].

### Example 76. Example of the balance opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# bamboo

bamboo — Semi-physical model of a bamboo sound.

## Description

*bamboo* is a semi-physical model of a bamboo sound. It is one of the PhISEM percussion opcodes. PhISEM (Physically Informed Stochastic Event Modeling) is an algorithmic approach for simulating collisions of multiple independent sound producing objects.

## Syntax

```
ares bamboo kamp, idettack [, inum] [, idamp] [, imaxshake] [, ifreq] \
[, ifreq1] [, ifreq2]
```

## Initialization

*idettack* -- period of time over which all sound is stopped

*inum* (optional) -- The number of beads, teeth, bells, timbrels, etc. If zero, the default value is 1.25.

*idamp* (optional) -- the damping factor, as part of this equation:

$$\text{damping\_amount} = 0.9999 + (\text{idamp} * 0.002)$$

The default *damping\_amount* is 0.9999 which means that the default value of *idamp* is 0. The maximum *damping\_amount* is 1.0 (no damping). This means the maximum value for *idamp* is 0.05.

The recommended range for *idamp* is usually below 75% of the maximum value.

*imaxshake* (optional, default=0) -- amount of energy to add back into the system. The value should be in range 0 to 1.

*ifreq* (optional) -- the main resonant frequency. The default value is 2800.

*ifreq1* (optional) -- the first resonant frequency. The default value is 2240.

*ifreq2* (optional) -- the second resonant frequency. The default value is 3360.

## Performance

*kamp* -- Amplitude of output. Note: As these instruments are stochastic, this is only an approximation.

## Examples

Here is an example of the bamboo opcode. It uses the file *bamboo.csd* [examples/bamboo.csd].

### Example 77. Example of the bamboo opcode.

# barmodel

barmodel — Creates a tone similar to a struck metal bar.

## Description

Audio output is a tone similar to a struck metal bar, using a physical model developed from solving the partial differential equation. There are controls over the boundary conditions as well as the bar characteristics.

## Syntax

```
ares barmodel kbcL, kbcR, iK, ib, kscan, iT30, ipos, ivel, iwid
```

## Initialization

*iK* -- dimensionless stiffness parameter. If this parameter is negative then the initialisation is skipped and the previous state of the bar is continued.

*ib* -- high-frequency loss parameter (keep this small).

*iT30* -- 30 db decay time in seconds.

*ipos* -- position along the bar that the strike occurs.

*ivel* -- normalized strike velocity.

*iwid* -- spatial width of strike.

## Performance

A note is played on a metallic bar, with the arguments as below.

*kbcL* -- Boundary condition at left end of bar (1 is clamped, 2 pivoting and 3 free).

*kbcR* -- Boundary condition at right end of bar (1 is clamped, 2 pivoting and 3 free).

*kscan* -- Speed of scanning the output location.

Note that changing the boundary conditions during playing may lead to glitches and is made available as an experiment. The use of a non-zero *kscan* can give apparent re-introduction of sound due to modulation.

## Examples

Here is an example of the barmodel opcode. It uses the file *barmodel.csd* [examples/barmodel.csd].

### Example 78. Example of the barmodel opcode.

# bbcutm

bbcutm — Generates breakbeat-style cut-ups of a mono audio stream.

## Description

The BreakBeat Cutter automatically generates cut-ups of a source audio stream in the style of drum and bass/jungle breakbeat manipulations. There are two versions, for mono (*bbcutm*) or stereo (*bbcuts*) sources. Whilst originally based on breakbeat cutting, the opcode can be applied to any type of source audio.

The prototypical cut sequence favoured over one bar with eighth note subdivisions would be

3+ 3R + 2

where we take a 3 unit block from the source's start, repeat it, then 2 units from the 7th and 8th eighth notes of the source.

We talk of rendering phrases (a sequence of cuts before reaching a new phrase at the beginning of a bar) and units (as subdivision th notes).

The opcode comes most alive when multiple synchronised versions are used simultaneously.

## Syntax

```
a1 bbcutm asource, ibps, isubdiv, ibarlength, iphrasebars, inumrepeats \
[, istutterspeed] [, istutterchance] [, ienvchoice ]
```

## Initialization

*ibps* -- Tempo to cut at, in beats per second.

*isubdiv* -- Subdivisions unit, for a bar. So 8 is eighth notes (of a 4/4 bar).

*ibarlength* -- How many beats per bar. Set to 4 for default 4/4 bar behaviour.

*iphrasebars* -- The output cuts are generated in phrases, each phrase is up to *iphrasebars* long

*inumrepeats* -- In normal use the algorithm would allow up to one additional repeat of a given cut at a time. This parameter allows that to be changed. Value 1 is normal- up to one extra repeat. 0 would avoid repeating, and you would always get back the original source except for enveloping and stuttering.

*istutterspeed* -- (optional, default=1) The stutter can be an integer multiple of the subdivision speed. For instance, if subdiv is 8 (quavers) and stutterspeed is 2, then the stutter is in semiquavers (sixteenth notes= subdiv 16). The default is 1.

*istutterchance* -- (optional, default=0) The tail of a phrase has this chance of becoming a single repeating one unit cell stutter (0.0 to 1.0). The default is 0.

*ienvchoice* -- (optional, default=1) choose 1 for on (exponential envelope for cut grains) or 0 for off. Off will cause clicking, but may give good noisy results, especially for percussive sources. The default is 1, on.

# Performance

*asource* -- The audio signal to be cut up. This version runs in real-time without knowledge of future audio.

## Examples

Here is a simple example of the *bbcutm* opcode. It uses the file *bbcutm.csd* [examples/bbcutm.csd], and *beats.wav* [examples/beats.wav].

### Example 79. A simple example of the **bbcutm** opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## bbcuts

bbcuts — Generates breakbeat-style cut-ups of a stereo audio stream.

## Description

The BreakBeat Cutter automatically generates cut-ups of a source audio stream in the style of drum and bass/jungle breakbeat manipulations. There are two versions, for mono (*bbcutm*) or stereo (*bbcups*) sources. Whilst originally based on breakbeat cutting, the opcode can be applied to any type of source audio.

The prototypical cut sequence favoured over one bar with eighth note subdivisions would be

3+ 3R + 2

where we take a 3 unit block from the source's start, repeat it, then 2 units from the 7th and 8th eighth notes of the source.

We talk of rendering phrases (a sequence of cuts before reaching a new phrase at the beginning of a bar) and units (as subdivision th notes).

The opcode comes most alive when multiple synchronised versions are used simultaneously.

## Syntax

```
a1,a2 bbcups asource1, asource2, ibps, isubdiv, ibarlength, iphrasebars, \
inumrepeats [, istutterspeed] [, istutterchance] [, ienvchoice]
```

## Initialization

*ibps* -- Tempo to cut at, in beats per second.

*isubdiv* -- Subdivisions unit, for a bar. So 8 is eighth notes (of a 4/4 bar).

*ibarlength* -- How many beats per bar. Set to 4 for default 4/4 bar behaviour.

*iphrasebars* -- The output cuts are generated in phrases, each phrase is up to *iphrasebars* long

*inumrepeats* -- In normal use the algorithm would allow up to one additional repeat of a given cut at a time. This parameter allows that to be changed. Value 1 is normal- up to one extra repeat. 0 would avoid repeating, and you would always get back the original source except for enveloping and stuttering.

*istutterspeed* -- (optional, default=1) The stutter can be an integer multiple of the subdivision speed. For instance, if subdiv is 8 (quavers) and stutterspeed is 2, then the stutter is in semiquavers (sixteenth notes= subdiv 16). The default is 1.

*istutterchance* -- (optional, default=0) The tail of a phrase has this chance of becoming a single repeating one unit cell stutter (0.0 to 1.0). The default is 0.

*ienvchoice* -- (optional, default=1) choose 1 for on (exponential envelope for cut grains) or 0 for off. Off will cause clicking, but may give good noisy results, especially for percussive sources. The default is 1, on.

# Performance

*asource* -- The audio signal to be cut up. This version runs in real-time without knowledge of future audio.

# betarand

betarand — Beta distribution random number generator (positive values only).

## Description

Beta distribution random number generator (positive values only). This is an x-class noise generator.

## Syntax

```
ares betarand krang, kalpha, kbta  
  
ires betarand krang, kalpha, kbta  
  
kres betarand krang, kalpha, kbta
```

## Performance

*krange* -- range of the random numbers (0 - *krange*).

*kalpha* -- alpha value. If *kalpha* is smaller than one, smaller values favor values near 0.

*kbeta* -- beta value. If *kbeta* is smaller than one, smaller values favor values near *krange*.

If both *kalpha* and *kbeta* equal one we have uniform distribution. If both *kalpha* and *kbeta* are greater than one we have a sort of Gaussian distribution. Outputs only positive numbers.

For more detailed explanation of these distributions, see:

1. C. Dodge - T.A. Jerse 1985. Computer music. Schirmer books. pp.265 - 286
2. D. Lorrain. A panoply of stochastic cannons. In C. Roads, ed. 1989. Music machine . Cambridge, Massachusetts: MIT press, pp. 351 - 379.

# bformdec1

bformdec1 — Decodes an ambisonic B format signal

## Description

Decodes an ambisonic B format signal into loudspeaker specific signals.

## Syntax

```
aol, ao2 bformdec1 isetup, aw, ax, ay, az [, ar, as, at, au, av \
[, abk, al, am, an, ao, ap, aq]]  
  
aol, ao2, ao3, ao4 bformdec1 isetup, aw, ax, ay, az [, ar, as, at, \
au, av [, abk, al, am, an, ao, ap, aq]]  
  
aol, ao2, ao3, ao4, ao5 bformdec1 isetup, aw, ax, ay, az [, ar, as, \
at, au, av [, abk, al, am, an, ao, ap, aq]]  
  
aol, ao2, ao3, ao4, ao5, ao6, ao7, ao8 bformdec1 isetup, aw, ax, ay, az \
[, ar, as, at, au, av [, abk, al, am, an, ao, ap,
aq]]]  
  
aout[] bformdec1 isetup, abform[]
```

## Initialization

Note that horizontal angles are measured anticlockwise in this description.

*isetup* -- loudspeaker setup. There are five supported setups:

- 1. Stereo - L(90), R(-90); this is an M+S style stereo decode.
- 2. Quad - FL(45), BL(135), BR(-135), FR(-45). This is a first-order `in-phase' decode.
- 3. 5.0 - L(30),R(-30),C(0),BL(110),BR(-110). Note that many people do not actually use the angles above for their speaker arrays and a good decode for DVD etc can be achieved using the Quad configuration to feed L, R, BL and BR (leaving C silent).
- 4. Octagon  
FFL(22.5),FLL(67.5),BLL(112.5),BBL(157.5),BBR(-157.5),BRR(-112.5),FRR(-67.5),FFR(-22.5).  
This is a first-, second- or third-order `in-phase' decode, depending on the number of input channels.
- 5. Cube  
FLD(45,-35.26),FLU(45,35.26),BLD(135,-35.26),BLU(135,35.26),BRD(-135,-35.26),BRU(-135,35.26),FRD(-45,-35.26),FRU(-45,35.26). This is a first-order `in-phase' decode.

## Performance

*aw, ax, ay, ...* -- input signal in the B format.

*ao1 .. ao8* -- loudspeaker specific output signals.

## Example

Here is an example of the bformdec1 opcode. It uses the file *bformenc1.csd* [examples/bformenc1.csd].

### Example 88. Example of the bformdec1 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# binit

binit — PVS tracks to amplitude+frequency conversion.

## Description

The binit opcode takes an input containing a TRACKS pv streaming signal (as generated, for instance by partials) and converts it into an equal-bandwidth bin-frame containing amplitude and frequency pairs (PVS\_AMP\_FREQ), suitable for overlap-add resynthesis (such as performed by pvsynth) or further PVS streaming phase vocoder signal transformations. For each frequency bin, it will look for a suitable track signal to fill it; if not found, the bin will be empty (0 amplitude). If more than one track fits a certain bin, the one with highest amplitude will be chosen. This means that not all of the input signal is actually 'binned', the operation is lossy. However, in many situations this loss is not perceptually relevant.

## Syntax

```
fsig binit fin, isize
```

## Performance

*fsig* -- output pv stream in PVS\_AMP\_FREQ format

*fin* -- input pv stream in TRACKS format

*isize* -- FFT size of output (N).

## Examples

Here is an example of the binit opcode. It uses the file *binit.csd* [examples/binit.csd].

### Example 89. Example of the binit opcode.

# biquad

*biquad* — A sweepable general purpose biquadratic digital filter.

## Description

A sweepable general purpose biquadratic digital filter.

## Syntax

```
ares biquad asig, kb0, kb1, kb2, ka0, ka1, ka2 [, iskip]
```

## Initialization

*iskip* (optional, default=0) -- if non-zero, initialization will be skipped. Default value 0. (New in Csound version 3.50)

## Performance

*asig* -- input signal

*biquad* is a general purpose biquadratic digital filter of the form:

$$a0*y(n) + a1*y[n-1] + a2*y[n-2] = b0*x[n] + b1*x[n-1] + b2*x[n-2]$$

This filter has the following frequency response:

$$H(Z) = \frac{B(Z)}{A(Z)} = \frac{b0 + b1*Z^{-1} + b2*Z^{-2}}{a0 + a1*Z^{-1} + a2*Z^{-2}}$$

This type of filter is often encountered in digital signal processing literature. It allows six user-defined k-rate coefficients.

## Examples

Here is an example of the biquad opcode. It uses the file *biquad.csd* [examples/biquad.csd].

### Example 90. Example of the biquad opcode.

# biquada

*biquada* — A sweepable general purpose biquadratic digital filter with a-rate parameters.

## Description

A sweepable general purpose biquadratic digital filter.

## Syntax

```
ares biquada asig, ab0, ab1, ab2, aa0, aa1, aa2 [, iskip]
```

## Initialization

*iskip* (optional, default=0) -- if non-zero, initialization will be skipped. Default value 0. (New in Csound version 3.50)

## Performance

*asig* -- input signal

*biquada* is a general purpose biquadratic digital filter of the form:

$$a0*y(n) + a1*y[n-1] + a2*y[n-2] = b0*x[n] + b1*x[n-1] + b2*x[n-2]$$

This filter has the following frequency response:

$$H(Z) = \frac{B(Z)}{A(Z)} = \frac{b0 + b1*Z^{-1} + b2*Z^{-2}}{a0 + a1*Z^{-1} + a2*Z^{-2}}$$

This type of filter is often encountered in digital signal processing literature. It allows six user-defined a-rate coefficients.

# birnd

birnd — Returns a random number in a bi-polar range.

## Description

Returns a random number in a bi-polar range.

## Syntax

```
birnd(x) (init- or control-rate only)
```

Where the argument within the parentheses may be an expression. These value converters sample a global random sequence, but do not reference *seed*. The result can be a term in a further expression.

## Performance

Returns a random number in the bipolar range  $-x$  to  $x$ . *rnd* and *birnd* obtain values from a global pseudo-random number generator, then scale them into the requested range. The single global generator will thus distribute its sequence to these units throughout the performance, in whatever order the requests arrive.

## Examples

Here is an example of the birnd opcode. It uses the file *birnd.csd* [examples/birnd.csd].

### Example 92. Example of the birnd opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# bqrez

`bqrez` — A second-order multi-mode filter.

## Description

A second-order multi-mode filter.

## Syntax

```
ares bqrez asig, xfco, xres [, imode] [, iskip]
```

## Initialization

*imode* (optional, default=0) -- The mode of the filter. Choose from one of the following:

- 0 = low-pass (default)
- 1 = high-pass
- 2 = band-pass
- 3 = band-reject
- 4 = all-pass

*iskip* (optional, default=0) -- if non zero skip the initialisation of the filter. (New in Csound version 4.23f13 and 5.0)

## Performance

*ares* -- output audio signal.

*asig* -- input audio signal.

*xfco* -- filter cut-off frequency in Hz. May be i-time, k-rate, a-rate.

*xres* -- amount of resonance. Values of 1 to 100 are typical. Resonance should be one or greater. A value of 100 gives a 20dB gain at the cutoff frequency. May be i-time, k-rate, a-rate.

All filter modes can be frequency modulated as well as the resonance can also be frequency modulated.

*bqrez* is a resonant low-pass filter created using the Laplace s-domain equations for low-pass, high-pass, and band-pass filters normalized to a frequency. The bi-linear transform was used which contains a frequency transform constant from s-domain to z-domain to exactly match the frequencies together. A lot of trigonometric identities were used to simplify the calculation. It is very stable across the working frequency range up to the Nyquist frequency.

## Examples

Here is an example of the *bqrez* opcode. It uses the file *bqrez.csd* [examples/bqrez.csd].

**Example 93. Example of the bqrez opcode borrowed from the “rezzy” opcode in Kevin Conder’s manual.**

# butterhp

butterhp — A high-pass Butterworth filter.

## Description

Implementation of second-order high-pass Butterworth filter. This opcode can also be written as *buthp*.

## Syntax

```
ares butterhp asig, kfreq [, iskip]  
  
ares butterhp asig, afreq [, iskip]
```

## Initialization

*iskip* (optional, default=0) -- Skip initialization if present and non-zero.

## Performance

These filters are Butterworth second-order IIR filters. They are slightly slower than the original filters in Csound, but they offer an almost flat passband and very good precision and stopband attenuation.

*asig* -- Input signal to be filtered.

*kfreq/afreq* -- Cutoff or center frequency for each of the filters.

## Examples

Here is an example of the butterhp opcode. It uses the file *butterhp.csd* [examples/butterhp.csd].

### Example 96. Example of the butterhp opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# button

button — Sense on-screen controls.

## Description

Sense on-screen controls. Requires Winsound or TCL/TK.

## Syntax

```
kres button knum
```

## Performance

Note that this opcode is not available on Windows due to the implementation of pipes on that system

*kres* -- value of the button control. If the button has been pushed since the last k-period, then return 1, otherwise return 0.

*knum* -- the number of the button. If it does not exist, it is made on-screen at initialization.

# buzz

**buzz** — Output is a set of harmonically related sine partials.

## Description

Output is a set of harmonically related sine partials.

## Syntax

```
ares buzz xamp, xcps, knh, ifn [, iphs]
```

## Initialization

*ifn* -- table number of a stored function containing a sine wave. A large table of at least 8192 points is recommended.

*iphs* (optional, default=0) -- initial phase of the fundamental frequency, expressed as a fraction of a cycle (0 to 1). A negative value will cause phase initialization to be skipped. The default value is zero

## Performance

*xamp* -- amplitude

*xcps* -- frequency in cycles per second

The *buzz* units generate an additive set of harmonically related cosine partials of fundamental frequency *xcps*, and whose amplitudes are scaled so their summation peak equals *xamp*. The selection and strength of partials is determined by the following control parameters:

*knh* -- total number of harmonics requested. New in Csound version 3.57, *knh* defaults to one. If *knh* is negative, the absolute value is used.

*buzz* and *gbuzz* are useful as complex sound sources in subtractive synthesis. *buzz* is a special case of the more general *gbuzz* in which *klh* = *kmul* = 1; it thus produces a set of *knh* equal-strength harmonic partials, beginning with the fundamental. (This is a band-limited pulse train; if the partials extend to the Nyquist, i.e. *knh* = int(sr / 2 / fundamental freq.), the result is a real pulse train of amplitude *xamp*.)

Although *knh* may be varied during performance, its internal value is necessarily integer and may cause “pops” due to discontinuities in the output. *buzz* can be amplitude- and/or frequency-modulated by either control or audio signals.

N.B. This unit has its analog in *GEN11*, in which the same set of cosines can be stored in a function table for sampling by an oscillator. Although computationally more efficient, the stored pulse train has a fixed spectral content, not a time-varying one as above.

## Examples

Here is an example of the *buzz* opcode. It uses the file *buzz.csd* [examples/buzz.csd].

### Example 98. Example of the buzz opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# c2r

c2r — Real to complex format conversion.

## Description

Converts a complex-valued input array into a real-valued array, by removing its imaginary part. The output array will be half the size of the input. This is a utility operation to facilitate complex-valued operations where the result is purely real.

## Syntax

```
kout[] c2r kin[]
```

## Performance

*kout[]* -- output array containing the real-valued output. It will be created if it does not exist.

*kin[]* -- input array containing the complex-valued real-imaginary input.

## Examples

Here is an example of the c2r opcode. It uses the file *c2r.csd* [examples/c2r.csd].

### Example 99. Example of the c2r opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# cabasa

`cabasa` — Semi-physical model of a cabasa sound.

## Description

`cabasa` is a semi-physical model of a cabasa sound. It is one of the PhISEM percussion opcodes. PhISEM (Physically Informed Stochastic Event Modeling) is an algorithmic approach for simulating collisions of multiple independent sound producing objects.

## Syntax

```
ares cabasa iamp, idettack [, inum] [, idamp] [, imaxshake]
```

## Initialization

*iamp* -- Amplitude of output. Note: As these instruments are stochastic, this is only a approximation.

*idettack* -- period of time over which all sound is stopped

*inum* (optional) -- The number of beads, teeth, bells, timbrels, etc. If zero, the default value is 512.

*idamp* (optional) -- the damping factor, as part of this equation:

$$\text{damping\_amount} = 0.998 + (\text{idamp} * 0.002)$$

The default *damping\_amount* is 0.997 which means that the default value of *idamp* is -0.5. The maximum *damping\_amount* is 1.0 (no damping). This means the maximum value for *idamp* is 1.0.

The recommended range for *idamp* is usually below 75% of the maximum value.

*imaxshake* (optional) -- amount of energy to add back into the system. The value should be in range 0 to 1.

## Examples

Here is an example of the cabasa opcode. It uses the file *cabasa.csd* [examples/cabasa.csd].

### Example 100. Example of the cabasa opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# cauchy

cauchy — Cauchy distribution random number generator.

## Description

Cauchy distribution random number generator. This is an x-class noise generator.

## Syntax

```
ares cauchy kalpha  
  
ires cauchy kalpha  
  
kres cauchy kalpha
```

## Performance

*kalpha* -- controls the spread from zero (big *kalpha* = big spread). Outputs both positive and negative numbers.

For more detailed explanation of these distributions, see:

1. C. Dodge - T.A. Jerse 1985. Computer music. Schirmer books. pp.265 - 286
2. D. Lorrain. A panoply of stochastic cannons. In C. Roads, ed. 1989. Music machine . Cambridge, Massachusetts: MIT press, pp. 351 - 379.

## Examples

Here is an example of the cauchy opcode. It uses the file *cauchy.csd* [examples/cauchy.csd].

### Example 101. Example of the cauchy opcode.

# cauchyi

cauchyi — Cauchy distribution random number generator with interpolation.

## Description

Cauchy distribution random number generator with controlled interpolation between values. This is an x-class noise generator.

## Syntax

```
ares cauchyi klambda, xamp, xcps  
  
ires cauchyi klambda, xamp, xcps  
  
kres cauchyi klambda, xamp, xcps
```

## Performance

*kalpha* -- controls the spread from zero (big *kalpha* = big spread). Outputs both positive and negative numbers.

For more detailed explanation of these distributions, see:

1. C. Dodge - T.A. Jerse 1985. Computer music. Schirmer books. pp.265 - 286
2. D. Lorrain. A panoply of stochastic cannons. In C. Roads, ed. 1989. Music machine . Cambridge, Massachusetts: MIT press, pp. 351 - 379.

*xamp* -- range over which random numbers are distributed.

*xcps* -- the frequency which new random numbers are generated.

## Examples

Here is an example of the cauchyi opcode. It uses the file *cauchyi.csd* [examples/cauchyi.csd].

### Example 102. Example of the cauchyi opcode.

# ceil

ceil — Returns the smallest integer not less than  $x$

## Description

Returns the smallest integer not less than  $x$

## Syntax

```
ceil(x) (init-, control-, or audio-rate arg allowed)
```

where the argument within the parentheses may be an expression. Value converters perform arithmetic translation from units of one kind to units of another. The result can then be a term in a further expression.

## Examples

Here is an example of the ceil opcode. It uses the file *ceil.csd* [examples/ceil.csd].

### Example 103. Example of the ceil opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# cell

cell — Cellular Automaton

## Description

One-Dimensional Cellular Automaton. This opcode is the modified version of *vcella* by Gabriel Mal-donado.

## Syntax

```
cell ktrig, kreinit, ioutFunc, initStateFunc, iRuleFunc, ielements
```

## Initialization

*ioutFunc* -- number of the table where the state of each cell is stored.

*initStateFunc* -- number of the table containing the initial states of cells.

*iRuleFunc* -- number of a lookup table containing the 8-bit rule.

*ielements* -- total number of cells in a row.

## Performance

*ktrig* -- trigger signal. Each time it is non-zero, a new generation of cells is evaluated.

*kreinit* -- reset signal. Each time it is non-zero, state of all cells is forced to be that of *initStateFunc*.

*cell* models a classical 1D cellular automaton and stores the state of each cell in the table identified by *ioutFunc*.

*initStateFunc* is an input vector containing the initial value of the row of cells, while *iRuleFunc* is an input vector containing the chosen rule in the binary form (least significant bit first).

A new generation of cells is evaluated each time *ktrig* contains a non-zero value. Also the status of all cells can be forced to assume the status corresponding to the contents of *initStateFunc* each time *kreinit* contains a non-zero value.

Note that each cell is supposed to be in one of two possible states (1 = "alive", 0 = "dead"), although fractional values should work too, because truncation is used.

## Examples

Here is a simple example of the cell opcode. It uses the file *cell.csd* [examples/cell.csd].

### Example 104. A simple example of the cell opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## cent

cent — Calculates a factor to raise/lower a frequency by a given amount of cents.

## Description

Calculates a factor to raise/lower a frequency by a given amount of cents.

## Syntax

```
cent(x)
```

This function works at a-rate, i-rate, and k-rate.

## Initialization

*x* -- a value expressed in cents.

## Performance

The value returned by the *cent* function is a factor. You can multiply a frequency by this factor to raise/lower it by the given amount of cents.

## Examples

Here is an example of the cent opcode. It uses the file *cent.csd* [examples/cent.csd].

### Example 105. Example of the cent opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>

# centroid

centroid — Calculate the spectral centroid of a signal.

## Description

Calculate the spectral centroid of an audio signal on a given trigger.

## Syntax

```
kcent centroid asig, ktrig, ifftsize
```

## Initialization

*ifftsize* -- fftsize. Non pow-of-two values are converted to the next pow-of-two not smaller than ifftsize.

## Performance

*kcent* -- the spectral centroid in Hz

*asig* -- an input audio signal

*ktrig* -- 1 to calculate a new centroid, 0 to skip the process (and output previous value).

## Examples

Here is an example of the centroid opcode. It uses the file *centroid.csd* [examples/centroid.csd].

### Example 106. Example of the centroid opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# cggoto

cggoto — Conditionally transfer control on every pass.

## Description

Transfer control to *label* on every pass. (Combination of *cigoto* and *ckgoto*)

## Syntax

```
cggoto condition, label
```

where *label* is in the same instrument block and is not an expression, and where *condition* uses one of the Relational operators (<, =, <=, ==, !=) (and = for convenience, see also under *Conditional Values*).

## Examples

Here is an example of the cggoto opcode. It uses the file *cggoto.csd* [examples/cggoto.csd].

### Example 107. Example of the cggoto opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# chanctrl

chanctrl — Get the current value of a MIDI channel controller.

## Description

Get the current value of a controller and optionally map it onto specified range.

## Syntax

```
ival chanctrl ichnl, ictlno [, ilow] [, ihigh]  
kval chanctrl ichnl, ictlno [, ilow] [, ihigh]
```

## Initialization

*ichnl* -- the MIDI channel (1-16).

*ictlno* -- the MIDI controller number (0-127).

*ilow*, *ihigh* -- low and high ranges for mapping

## Examples

Here is an example of the chanctrl opcode. It uses the file *chanctrl.csd* [examples/chanctrl.csd].

### Example 108. Example of the chanctrl opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# changed

changed — k-rate signal change detector.

## Description

This opcode outputs a trigger signal that informs when any one of its k-rate arguments has changed. Useful with valuator widgets or MIDI controllers.

## Syntax

```
ktrig changed kvar1 [, kvar2,..., kvarN]
```

## Performance

*ktrig* - Outputs a value of 1 when any of the k-rate signals has changed, otherwise outputs 0.

*kvar1* [, *kvar2*,..., *kvarN*] - k-rate variables to watch for changes.

## Examples

Here is an example of the changed opcode. It uses the file *changed.csd* [examples/changed.csd].

### Example 109. Example of the changed opcode.

```

# chani

chani — Reads data from the software bus

## Description

Reads data from a channel of the inward software bus.

## Syntax

```
kval chani kchan
```

```
aval chani kchan
```

## Performance

*kchan* -- a positive integer that indicates which channel of the software bus to read

Note that the inward and outward software busses are independent, and are not mixer buses. Also the k-rate and a-rate busses are independent. The last value remains until a new value is written. There is no imposed limit to the number of busses but they use memory so small numbers are to be preferred.

## Example

The example shows the software bus being used as an asynchronous control signal to select a filter cutoff. It assumes that an external program that has access to the API is feeding the values

```
sr = 44100
kr = 100
ksmps = 1

instr 1
kc chani 1
a1 oscil p4, p5, 100
a2 lowpass2 a1, kc, 200
out a2
endin
```

# chano

chano — Send data to the outwards software bus

## Description

Send data to a channel of the outward software bus.

## Syntax

```
chano kval, kchan  
  
chano aval, kchan
```

## Performance

*xval* --- value to transmit

*kchan* -- a positive integer that indicates which channel of the software bus to write

Note that the inward and outward software busses are independent, and are not mixer buses. Also the k-rate and a-rate busses are independent. The last value remains until a new value is written. There is no imposed limit to the number of busses but they use memory so small numbers are to be preferred.

## Example

The example shows the software bus being used as an output audio channel. It assumes that an external program that has access to the API is receiving the values.

```
sr = 44100  
kr = 100  
ksmps = 1  
  
instr 1  
    al oscil     p4, p5, 100  
    chano 1, al  
endin
```

# chebyshevpoly

`chebyshevpoly` — Efficiently evaluates the sum of Chebyshev polynomials of arbitrary order.

## Description

The `chebyshevpoly` opcode calculates the value of a polynomial expression with a single a-rate input variable that is made up of a linear combination of the first N Chebyshev polynomials of the first kind. Each Chebyshev polynomial,  $T_n(x)$ , is weighted by a k-rate coefficient,  $k_n$ , so that the opcode is calculating a sum of any number of terms in the form  $k_n * T_n(x)$ . Thus, the `chebyshevpoly` opcode allows for the waveshaping of an audio signal with a *dynamic* transfer function that gives precise control over the harmonic content of the output.

## Syntax

```
aout chebyshevpoly ain, k0 [, k1 [, k2 [...]]]
```

## Performance

*ain* -- the input signal used as the independent variable of the Chebyshev polynomials ("x").

*aout* -- the output signal ("y").

*k0, k1, k2, ...* -- k-rate multipliers for each Chebyshev polynomial.

This opcode is very useful for dynamic waveshaping of an audio signal. Traditional waveshaping techniques utilize a lookup table for the transfer function -- usually a sum of Chebyshev polynomials. When a sine wave at full-scale amplitude is used as an index to read the table, the precise harmonic spectrum as defined by the weights of the Chebyshev polynomials is produced. A dynamic spectrum is achieved by varying the amplitude of the input sine wave, but this produces a non-linear change in the spectrum.

By directly calculating the Chebyshev polynomials, the `chebyshevpoly` opcode allows more control over the spectrum and the number of harmonic partials added to the input can be varied with time. The value of each  $k_n$  coefficient directly controls the amplitude of the  $n$ th harmonic partial if the input *ain* is a sine wave with amplitude = 1.0. This makes `chebyshevpoly` an efficient additive synthesis engine for N partials that requires only one oscillator instead of N oscillators. The amplitude or waveform of the input signal can also be changed for different waveshaping effects.

If we consider the input parameter *ain* to be "x" and the output *aout* to be "y", then the `chebyshevpoly` opcode calculates the following equation:

$$y = k0*T0(x) + k1*T1(x) + k2*T2(x) + k3*T3(x) + \dots$$

where the  $T_n(x)$  are defined by the recurrence relation

$$\begin{aligned} T0(x) &= 1, \\ T1(x) &= x, \\ Tn(x) &= 2x*T[n-1](x) - T[n-2](x) \end{aligned}$$

More information about Chebyshev polynomials can be found on Wikipedia at [http://en.wikipedia.org/wiki/Chebyshev\\_polynomial](http://en.wikipedia.org/wiki/Chebyshev_polynomial) [[http://en.wikipedia.org/wiki/Chebyshev\\_polynomial](http://en.wikipedia.org/wiki/Chebyshev_polynomial)]

# checkbox

checkbox — Sense on-screen controls.

## Description

Sense on-screen controls. Requires Winsound or TCL/TK.

## Syntax

```
kres checkbox knum
```

## Performance

Note that this opcode is not available on Windows due to the implementation of pipes on that system

*kres* -- value of the checkbox control. If the checkbox is set (pushed) then return 1, if not, return 0.

*knum* -- the number of the checkbox. If it does not exist, it is made on-screen at initialization.

## Examples

Here is a simple example of the checkbox opcode. It uses the file *checkbox.csd* [examples/checkbox.csd].

### Example 111. Simple example of the checkbox opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# chn

chn — Declare a channel of the named software bus.

## Description

Declare a channel of the named software bus, with setting optional parameters in the case of a control channel. If the channel does not exist yet, it is created, with an initial value of zero or empty string. Otherwise, the type (control, audio, or string) of the existing channel must match the declaration, or an init error occurs. The input/output mode of an existing channel is updated so that it becomes the bitwise OR of the previous and the newly specified value.

## Syntax

```
chn_k Sname, imode[, itype, idflt, imin, ima, ix, iy, iwidth, iheight, Sattributes]  
  
chn_a Sname, imode  
  
chn_s Sname, imode
```

## Initialization

*imode* -- sum of at least one of 1 for input and 2 for output.

*itype* (optional, defaults to 0) -- channel subtype for control channels only. Possible values are:

- 0: default/unspecified (*idflt*, *imin*, and *imax* are ignored)
- 1: integer values only
- 2: linear scale
- 3: exponential scale

*idflt* (optional, defaults to 0) -- default value, for control channels with non-zero *itype* only. Must be greater than or equal to *imin*, and less than or equal to *imax*.

*imin* (optional, defaults to 0) -- minimum value, for control channels with non-zero *itype* only. Must be non-zero for exponential scale (*itype* = 3).

*imax* (optional, defaults to 0) -- maximum value, for control channels with non-zero *itype* only. Must be greater than *imin*. In the case of exponential scale, it should also match the sign of *imin*.

*ix* -- suggested x position for controller.

*iy* -- suggested y position for controller.

*iwidth* -- suggested width position for controller.

*iheight* -- suggested height position for controller.

*Sattributes* -- attributes for controller.

## Notes

The channel parameters (*imode*, *itype*, *idflt*, *imin*, and *imax*) are only hints for the host application or external software accessing the bus through the API, and do not actually restrict reading from or writing to the channel in any way. Also, the initial value of a newly created control channel is zero, regardless of the setting of *idflt*.

For communication with external software, using *chnexport* may be preferred, as it allows direct access to orchestra variables exported as channels of the bus, eliminating the need for using *chnset* and *chnget* to send or receive data.

## Performance

**chn\_k**, **chn\_a**, and **chn\_S** declare a control, audio, or string channel, respectively.

## Example

The example shows the software bus being used as an asynchronous control signal to select a filter cutoff. It assumes that an external program that has access to the API is feeding the values.

```
sr = 44100
kr = 100
ksmps = 1

chn_k "cutoff", 1, 3, 1000, 500, 2000

instr 1
    kc  chnget    "cutoff"
    a1  oscil     p4, p5, 100
    a2  lowpass2  a1, kc, 200
    out a2
endin
```

# chnclear

chnclear — Clears an audio output channel of the named software bus.

## Description

Clears an audio channel of the named software bus to zero. Implies declaring the channel with *imode*=2 (see also *chn\_a*).

## Syntax

```
chnclear Sname
```

## Initialization

*Sname* -- a string that indicates which named channel of the software bus to clear.

## Examples

Here is an example of the chnuclear opcode. It uses the file *chnuclear.csd* [examples/chnuclear.csd].

### Example 112. Example of the chnuclear opcode.

# chnexport

chnexport — Export a global variable as a channel of the bus.

## Description

Export a global variable as a channel of the bus; the channel should not already exist, otherwise an init error occurs. This opcode is normally called from the orchestra header, and allows the host application to read or write orchestra variables directly, without having to use *chnget* or *chnset* to copy data.

## Syntax

```
gival chnexport Sname, imode[, itype, idflt, imin, imax]  
  
gkval chnexport Sname, imode[, itype, idflt, imin, imax]  
  
gaval chnexport Sname, imode  
  
gSval chnexport Sname, imode
```

## Initialization

*imode* -- sum of at least one of 1 for input and 2 for output.

*itype* (optional, defaults to 0) -- channel subtype for control channels only. Possible values are:

- 0: default/unspecified (*idflt*, *imin*, and *imax* are ignored)
- 1: integer values only
- 2: linear scale
- 3: exponential scale

*idflt* (optional, defaults to 0) -- default value, for control channels with non-zero *itype* only. Must be greater than or equal to *imin*, and less than or equal to *imax*.

*imin* (optional, defaults to 0) -- minimum value, for control channels with non-zero *itype* only. Must be non-zero for exponential scale (*itype* = 3).

*imax* (optional, defaults to 0) -- maximum value, for control channels with non-zero *itype* only. Must be greater than *imin*. In the case of exponential scale, it should also match the sign of *imin*.

## Notes

The channel parameters (*imode*, *itype*, *idflt*, *imin*, and *imax*) are only hints for the host application or external software accessing the bus through the API, and do not actually restrict reading from or writing to the channel in any way.

While the global variable is used as output argument, *chnexport* does not actually change it, and always runs at i-time only. If the variable is not previously declared, it is created by Csound with an initial value

of zero or empty string.

## Example

The example shows the software bus being used as an asynchronous control signal to select a filter cutoff. It assumes that an external program that has access to the API is feeding the values.

```
sr = 44100
kr = 100
ksmps = 1

gkc init 1000 ; set default value
gkc chnexport "cutoff", 1, 3, i(gkc), 500, 2000

instr 1
    a1 oscil p4, p5, 100
    a2 lowpass2 a1, gkc, 200
    out a2
endin
```

# chnget

chnget — Reads data from the software bus.

## Description

Reads data from a channel of the inward named software bus. Implies declaring the channel with *imode*=1 (see also *chn\_k*, *chn\_a*, and *chn\_S*).

## Syntax

```
ival chnget Sname  
  
kval chnget Sname  
  
aval chnget Sname  
  
Sval chnget Sname
```

## Initialization

*Sname* -- a string that identifies a channel of the named software bus to read.

*ival* -- the control value read at i-time.

*Sval* -- the string value read at i-time.

## Performance

*kval* -- the control value read at performance time.

*aval* -- the audio signal read at performance time.

## Example

The example shows the software bus being used as an asynchronous control signal to select a filter cutoff. It assumes that an external program that has access to the API is feeding the values.

```
sr = 44100  
kr = 100  
ksmps = 1  
  
instr 1  
    kc chnget    "cutoff"  
    a1 oscil     p4, p5, 100  
    a2 lowpass2  a1, kc, 200  
    out         a2  
endin
```

Here is another example of the chnget opcode. It uses the file *chnget.csd* [examples/chnget.csd].

**Example 113. Example of the chnget opcode.**

# chnmix

chnmix — Writes audio data to the named software bus, mixing to the previous output.

## Description

Adds an audio signal to a channel of the named software bus. Implies declaring the channel with *imode*=2 (see also *chn\_a*).

## Syntax

```
chnmix aval, Sname
```

## Initialization

*Sname* -- a string that indicates which named channel of the software bus to write.

## Performance

*aval* -- the audio signal to write at performance time.

## Examples

Here is an example of the chnmix opcode. It uses the file *chnmix.csd* [examples/chnmix.csd].

### Example 114. Example of the chnmix opcode.

```

# chnparams

chnparams — Query parameters of a channel.

## Description

Query parameters of a channel (if it does not exist, all returned values are zero).

## Syntax

```
itype, imode, ictltype, idflt, imin, imax chnparams
```

## Initialization

*itype* -- channel data type (1: control, 2: audio, 3: string)

*imode* -- sum of 1 for input and 2 for output

*ictltype* -- special parameter for control channel only; if not available, set to zero.

*idflt* -- special parameter for control channel only; if not available, set to zero.

*imin* -- special parameter for control channel only; if not available, set to zero.

*imax* -- special parameter for control channel only; if not available, set to zero.

# chnset

chnset — Writes data to the named software bus.

## Description

Write to a channel of the named software bus. Implies declaring the channel with *imod*=2 (see also *chn\_k*, *chn\_a*, and *chn\_S*).

## Syntax

```
chnset ival, Sname  
  
chnset kval, Sname  
  
chnset aval, Sname  
  
chnset Sval, Sname
```

## Initialization

*Sname* -- a string that indicates which named channel of the software bus to write.

*ival* -- the control value to write at i-time.

*Sval* -- the string value to write at i-time.

## Performance

*kval* -- the control value to write at performance time.

*aval* -- the audio signal to write at performance time.

## Example

The example shows the software bus being used to write pitch information to a controlling program.

```
sr = 44100  
kr = 100  
ksmps = 1  
  
instr 1  
    al in  
    kp,ka pitchamdf al  
    chnset kp, "pitch"  
endin
```

Here is another example of the chnset opcode. It uses the file *chnset.csd* [examples/chnset.csd].

# chuap

**chuap** — Simulates Chua's oscillator, an LRC oscillator with an active resistor, proved capable of bifurcation and chaotic attractors, with k-rate control of circuit elements.

## Description

Simulates Chua's oscillator, an LRC oscillator with an active resistor, proved capable of bifurcation and chaotic attractors, with k-rate control of circuit elements.

## Syntax

```
aI3, aV2, aV1 chuap kL, kR0, kC1, kG, kGa, kGb, kE, kC2, iI3, iV2, iV1, ktime_step
```

## Initialization

*iI3* -- Initial current at G

*iV2* -- Initial voltage at C2

*iV1* -- Initial voltage at C1

## Performance

*kL* -- Inductor L

*kR0* -- Resistor R0

*kC1* -- Capacitor C1

*kG* -- Resistor G

*kGa* -- Resistor V (nonlinearity term)

*kGb* -- Resistor V (nonlinearity term)

*kGb* -- Resistor V (nonlinearity term)

*ktime\_step* -- Delta time in the difference equation, can be used to more or less control pitch.

*Chua's oscillator* is a simple LRC oscillator with an active resistor. The oscillator can be driven into period bifurcation, and thus to chaos, because of the nonlinear response of the active resistor.

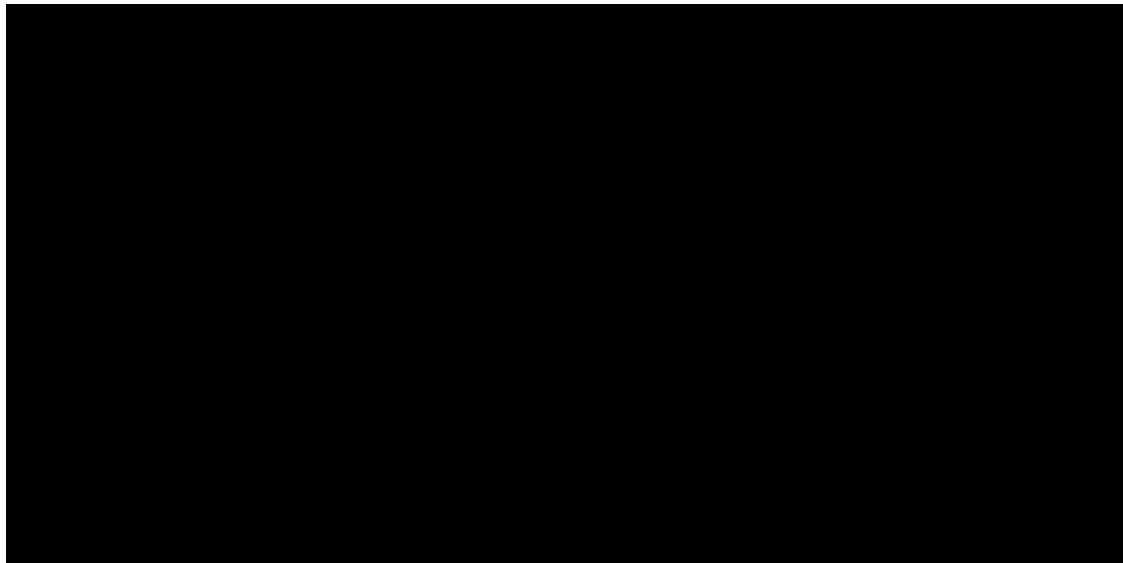

Diagram of Chua's Oscillator Circuit

The circuit is described by a set of three ordinary differential equations called Chua's equations:

$$\frac{dI_3}{dt} = \frac{R_0}{L} I_3 - \frac{1}{L} V_2$$

$$\frac{dV_2}{dt} = \frac{1}{C_2} I_3 - \frac{G}{C_2} (V_2 - V_1)$$

$$\frac{dV_1}{dt} = \frac{G}{C_1} (V_2 - V_1) - \frac{1}{C_1} f(V_1)$$

where  $f()$  is a piecewise discontinuity simulating the active resistor:

$$f(V_1) = G_b V_1 + (G_a - G_b)(|V_1 + E| - |V_1 - E|)$$

A solution of these equations  $(I_3, V_2, V_1)(t)$  starting from an initial state  $(I_3, V_2, V_1)(0)$  is called a trajectory of Chua's oscillator. The Csound implementation is a difference equation simulation of Chua's oscillator with Runge-Kutta integration.

### Note

This algorithm uses internal non linear feedback loops which causes audio result to depend on the orchestra sampling rate. For example, if you develop a project with  $sr=48000\text{Hz}$  and if you want to produce an audio CD from it, you should record a file with  $sr=48000\text{Hz}$  and then downsample the file to  $44100\text{Hz}$  using the *srconv* utility.

## Warning

Be careful! Some sets of parameters will produce amplitude spikes or positive feedback that could damage your speakers.

# Examples

Here is an example of the chuap opcode. It uses the file *chuap.csd* [examples/chuap.csd].

# cigoto

cigoto — Conditionally transfer control during the i-time pass.

## Description

During the i-time pass only, conditionally transfer control to the statement labeled by *label*.

## Syntax

```
cigoto condition, label
```

where *label* is in the same instrument block and is not an expression, and where *condition* uses one of the Relational operators (<, =, <=, ==, !=) (and = for convenience, see also under *Conditional Values*).

## Examples

Here is an example of the cigoto opcode. It uses the file *cigoto.csd* [examples/cigoto.csd].

### Example 117. Example of the cigoto opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>

# ckgoto

ckgoto — Conditionally transfer control during the p-time passes.

## Description

During the p-time passes only, conditionally transfer control to the statement labeled by *label*.

## Syntax

```
ckgoto condition, label
```

where *label* is in the same instrument block and is not an expression, and where *condition* uses one of the Relational operators ( $<$ ,  $=$ ,  $\leq$ ,  $\equiv$ ,  $\neq$ ) (and  $=$  for convenience, see also under *Conditional Values*).

## Examples

Here is an example of the ckgoto opcode. It uses the file *ckgoto.csd* [examples/ckgoto.csd].

### Example 118. Example of the ckgoto opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out  Audio in   No messages
-odac      -iadc    -d     ;;;RT audio I/O
; For Non-realtime output leave only the line below:
; -o ckgoto.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

; Initialize the global variables.
sr = 44100
kr = 4410
ksmps = 10
nchnls = 1

; Instrument #1.
instr 1
; Change kval linearly from 0 to 2 over
; the period set by the third p-field.
kval line 0, p3, 2
; If kval is greater than or equal to 1 then play the high note.
; If not then play the low note.
ckgoto (kval >= 1), highnote
    kgoto lownote

highnote:
    kfreq = 880
    goto playit

lownote:
    kfreq = 440
    goto playit

playit:
; Print the values of kval and kfreq.
```

```
printks "kval = %f, kfreq = %f\n", 1, kval, kfreq
a1 oscil 10000, kfreq, 1
    out a1
endin

</CsInstruments>

# clear

`clear` — Zeroes a list of audio signals.

## Description

*clear* zeroes a list of audio signals.

## Syntax

```
clear avar1 [, avar2] [, avar3] [...]
```

## Performance

*avar1, avar2, avar3, ...* -- signals to be zeroed

*clear* sets every sample of each of the given audio signals to zero when it is performed. This is equivalent to writing *avarN = 0* in the orchestra for each of the specified variables. Typically, *clear* is used with global variables that combine multiple signals from different sources and change with each k-pass (performance loop) through all of the active instrument instances. After the final usage of such a variable and before the next k-pass, it is necessary to clear the variable so that it does not add the next cycle's signals to the previous result. *clear* is especially useful in combination with *vincr* (variable increment) and they are intended to be used together with file output opcodes such as *fout*.

## Examples

Here is an example of the *clear* opcode. It uses the file *clear.csd* [examples/clear.csd].

### Example 119. Example of the clear opcode.

```

# clfilt

clfilt — Implements low-pass and high-pass filters of different styles.

## Description

Implements the classical standard analog filter types: low-pass and high-pass. They are implemented with the four classical kinds of filters: Butterworth, Chebyshev Type I, Chebyshev Type II, and Elliptical. The number of poles may be any even number from 2 to 80.

## Syntax

```
ares clfilt asig, kfreq, itype, inpol [, ikind] [, ipbr] [, isba] [, iskip]
```

## Initialization

*itype* -- 0 for low-pass, 1 for high-pass.

*inpol* -- The number of poles in the filter. It must be an even number from 2 to 80.

*ikind* (optional) -- 0 for Butterworth, 1 for Chebyshev Type I, 2 for Chebyshev Type II, 3 for Elliptical. Defaults to 0 (Butterworth)

*ipbr* (optional) -- The pass-band ripple in dB. Must be greater than 0. It is ignored by Butterworth and Chebyshev Type II. The default is 1 dB.

*isba* (optional) -- The stop-band attenuation in dB. Must be less than 0. It is ignored by Butterworth and Chebyshev Type I. The default is -60 dB.

*iskip* (optional) -- 0 initializes all filter internal states to 0. 1 skips initialization. The default is 0.

## Performance

*asig* -- The input audio signal.

*kfreq* -- The corner frequency for low-pass or high-pass.

## Examples

Here is an example of the clfilt opcode as a low-pass filter. It uses the file *clfilt\_lowpass.csd* [examples/clfilt\_lowpass.csd].

### Example 120. Example of the clfilt opcode as a low-pass filter.

# clip

clip — Clips a signal to a predefined limit.

## Description

Clips an a-rate signal to a predefined limit, in a “soft” manner, using one of three methods.

## Syntax

```
ares clip asig, imeth, ilimit [, iarg]
```

## Initialization

*imeth* -- selects the clipping method. The default is 0. The methods are:

- 0 = Bram de Jong method (default)
- 1 = sine clipping
- 2 = tanh clipping

*ilimit* -- limiting value

*iarg* (optional, default=0.5) -- when *imeth* = 0, indicates the point at which clipping starts, in the range 0 - 1. Not used when *imeth* = 1 or *imeth* = 2. Default is 0.5.

## Performance

*asig* -- a-rate input signal

The Bram de Jong method (*imeth* = 0) applies the algorithm (denoting *ilimit* as *limit* and *iarg* as *a*):

$$\begin{cases} |x| \geq 0 \text{ and } |x| \leq (limit * a): & f(x) = f(x) \\ |x| > (limit * a) \text{ and } |x| \leq limit: & f(x) = sign(x) * (limit * a + (x - limit * a) / (1 + ((x - limit * a) / (limit * (1 - a))))) \\ |x| > limit: & f(x) = sign(x) * (limit * (1 + a)) / 2 \end{cases}$$

The second method (*imeth* = 1) is the sine clip:

$$|x| < limit: f(x) = limit * sin(\#*x/(2*limit)), \quad |x| \geq limit: f(x) = limit * sign(x)$$

The third method (*imeth* = 2) is the tanh clip:

```
|x| < limit: f(x) = limit * tanh(x/limit)/tanh(1), |x| >= limit: f(x) = limit * sign(x)
```

## Note

Method 1 appears to be non-functional at release of Csound version 4.07.

# Examples

Here is an example of the clip opcode. It uses the file *clip.csd* [examples/clip.csd].

### Example 122. Example of the clip opcode.

# clockoff

clockoff — Stops one of a number of internal clocks.

## Description

Stops one of a number of internal clocks.

## Syntax

```
clockoff inum
```

## Initialization

*inum* -- the number of a clock. There are 32 clocks numbered 0 through 31. All other values are mapped to clock number 32.

## Performance

Between a *clockon* and a *clockoff* opcode, the CPU time used is accumulated in the clock. The precision is machine dependent but is the millisecond range on UNIX and Windows systems. The *readclock* opcode reads the current value of a clock at initialization time.

## Examples

Here is an example of the *clockoff* opcode. It uses the file *clockoff.csd* [examples/clockoff.csd].

### Example 123. Example of the *clockoff* opcode.

# comb

comb — Reverberates an input signal with a “colored” frequency response.

## Description

Reverberates an input signal with a “colored” frequency response.

## Syntax

```
ares comb asig, krvt, ilpt [, iskip] [, insmps]
```

## Initialization

*ilpt* -- loop time in seconds, which determines the “echo density” of the reverberation. This in turn characterizes the “color” of the *comb* filter whose frequency response curve will contain  $ilpt * sr/2$  peaks spaced evenly between 0 and  $sr/2$  (the Nyquist frequency). Loop time can be as large as available memory will permit. The space required for an *n* second loop is  $n*sr$  floating or double numbers (usually 4 or 8 bytes). Delay space is allocated and returned as in *delay*.

*iskip* (optional, default=0) -- initial disposition of delay-loop data space (cf. *reson*). The default value is 0.

*insmps* (optional, default=0) -- delay amount, as a number of samples.

## Performance

*krvt* -- the reverberation time (defined as the time in seconds for a signal to decay to 1/1000, or 60dB down from its original amplitude).

This filter reiterates input with an echo density determined by loop time *ilpt*. The attenuation rate is independent and is determined by *krvt*, the reverberation time (defined as the time in seconds for a signal to decay to 1/1000, or 60dB down from its original amplitude). Output from a *comb* filter will appear only after *ilpt* seconds.

## Examples

Here is an example of the *comb* opcode. It uses the file *comb.csd* [examples/comb.csd].

### Example 127. Example of the *comb* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# combinv

combinv — Reverberates an input signal with a “colored” frequency response.

## Description

Reverberates an input signal with a “colored” frequency response with a FIR filter.

## Syntax

```
ares combinv asig, krvt, ilpt [, iskip] [, insmps]
```

## Initialization

*ilpt* -- loop time in seconds, which determines the “echo density” of the reverberation. This in turn characterizes the “color” of the *combinv* filter whose frequency response curve will contain  $ilpt * sr/2$  peaks spaced evenly between 0 and  $sr/2$  (the Nyquist frequency). Loop time can be as large as available memory will permit. The space required for an *n* second loop is  $n*sr$  floating or double numbers (usually 4 or 8 bytes). Delay space is allocated and returned as in *delay*.

*iskip* (optional, default=0) -- initial disposition of delay-loop data space (cf. *reson*). The default value is 0.

*insmps* (optional, default=0) -- delay amount, as a number of samples.

## Performance

*krvt* -- the reverberation time (defined as the time in seconds for a signal to decay to 1/1000, or 60dB down from its original amplitude).

This filter reiterates input with an echo density determined by loop time *ilpt*. The attenuation rate is independent and is determined by *krvt*, the reverberation time (defined as the time in seconds for a signal to decay to 1/1000, or 60dB down from its original amplitude). Affect from a *combinv* filter will appear only after *ilpt* seconds.

## Examples

Here is an example of the *combinv* opcode. It uses the file *combinv.csd* [examples/combinv.csd].

### Example 128. Example of the *combinv* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# compress

**compress** — Compress, limit, expand, duck or gate an audio signal.

## Description

This unit functions as an audio compressor, limiter, expander, or noise gate, using either soft-knee or hard-knee mapping, and with dynamically variable performance characteristics. It takes two audio input signals, *aasig* and *acsig*, the first of which is modified by a running analysis of the second. Both signals can be the same, or the first can be modified by a different controlling signal.

**compress** first examines the controlling *acsig* by performing envelope detection. This is directed by two control values *katt* and *krel*, defining the attack and release time constants (in seconds) of the detector. The detector rides the peaks (not the RMS) of the control signal. Typical values are .01 and .1, the latter usually being similar to *ilook*.

The running envelope is next converted to decibels, then passed through a mapping function to determine what compressor action (if any) should be taken. The mapping function is defined by four decibel control values. These are given as positive values, where 0 db corresponds to an amplitude of 1, and 90 db corresponds to an amplitude of 32768.

## Syntax

```
ar compress aasig, acsig, kthresh, kloknee, khiknee, kratio, katt, krel, ilook
```

## Initialization

*ilook* -- lookahead time in seconds, by which an internal envelope release can sense what is coming. This induces a delay between input and output, but a small amount of lookahead improves the performance of the envelope detector. Typical value is .05 seconds, sufficient to sense the peaks of the lowest frequency in *acsig*.

## Performance

*kthresh* -- sets the lowest decibel level that will be allowed through. Normally 0 or less, but if higher the threshold will begin removing low-level signal energy such as background noise.

*kloknee*, *khiknee* -- decibel break-points denoting where compression or expansion will begin. These set the boundaries of a soft-knee curve joining the low-amplitude 1:1 line and the higher-amplitude compression ratio line. Typical values are 48 and 60 db. If the two breakpoints are equal, a hard-knee (angled) map will result.

*kratio* -- ratio of compression when the signal level is above the knee. The value 2 will advance the output just one decibel for every input gain of two; 3 will advance just one in three; 20 just one in twenty, etc. Inverse ratios will cause signal expansion: .5 gives two for one, .25 four for one, etc. The value 1 will result in no change.

The actions of **compress** will depend on the parameter settings given. A hard-knee compressor-limiter, for instance, is obtained from a near-zero attack time, equal-value break-points, and a very high ratio (say 100). A noise-gate plus expander is obtained from some positive threshold, and a fractional ratio above the knee. A voice-activated music compressor (ducker) will result from feeding the music into *aasig* and the speech into *acsig*. A voice de-esser will result from feeding the voice into both, with the *acsig* version being preceded by a band-pass filter that emphasizes the sibilants. Each application will

require some experimentation to find the best parameter settings; these have been made k-variable to make this practical.

## Examples

# compilecsd

compilecsd — compiles a new orchestra from an ASCII file

## Description

Compilecsd will read a CSD file and compile one or more instruments at init time, which will be added to the running engine. In case of existing instrument numbers or names, these will be replaced, but any instance still running of the old instrument definition will still perform until it terminates. In addition, it will read the score (if it exists) contained in the CSD file and add it to the list of events to be performed by Csound. The opcode ignores any section in the CSD file that is not the orchestra or the score.

## Syntax

```
ires compilecsd Sfilename
```

## Initialization

“*Sfilename*” -- a string containing the name of the file containing the orchestra.

“*ires*” -- returns 0 if compilation was successful, or -1 if not.

## Examples

Here is an example of the compilecsd opcode. It uses the file *compilecsd.csd* [examples/compilecsd.csd].

### Example 130. Example of the compilecsd opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# compilestr

compilestr — compiles a new orchestra passed in as an ASCII string

## Description

Compilestr will compile one or more instruments at init time, which will be added to the running engine. In case of existing instrument numbers or names, these will be replaced, but any instance still running of the old instrument definition will still perform until it terminates. Only new instances will use the new definition. Multi-line strings are accepted, using {{ }} to enclose the string.

## Syntax

```
ires compilestr Sorch
```

## Initialization

“Sorch” -- a string (in double-quotes or enclosed by {{ }}) containing one or more instruments.

“ires” -- returns 0 if compilation was successful, or -1 if not.

## Examples

Here is an example of the compilestr opcode. It uses the file *compilestr.csd* [examples/compilestr.csd].

### Example 132. Example of the compilestr opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# connect

connect — Connects a source outlet to a sink inlet.

## Description

The connect opcode, valid only in the orchestra header, sends the signals from the indicated outlet in all instances of the indicated source instrument to the indicated inlet in all instances of the indicated sink instrument. Each inlet instance receives the sum of the signals in all outlet instances. Thus multiple instances of an outlet may fan in to one instance of an inlet, or one instance of an outlet may fan out to multiple instances of an inlet.

When Csound creates a new instance of an instrument template, new instances of its connections also are created.

## Syntax

```
connect Tsource1, Soutlet1, Tsink1, Sinlet1
```

## Initialization

*Tsource1* -- String name of the source instrument definition.

*Soutlet1* -- String name of the source outlet in the source instrument.

*Tsink1* -- String name of the sink instrument definition.

*Sinlet1* -- String name of the sink inlet in the sink instrument.

## Examples

Here is an example of the connect opcode. It uses the file *connect.csd* [examples/connect.csd].

# control

control — Configurable slider controls for realtime user input.

## Description

Configurable slider controls for realtime user input. Requires Winsound or TCL/Tk. *control* reads a slider's value.

## Syntax

```
kres control knum
```

## Performance

Note that this opcode is not available on Windows due to the implementation of pipes on that system

*knum* -- number of the slider to be read.

Calling *control* will create a new slider on the screen. There is no theoretical limit to the number of sliders. Windows and TCL/Tk use only integers for slider values, so the values may need rescaling. GUIs usually pass values at a fairly slow rate, so it may be advisable to pass the output of control through *port*.

## Examples

See the *setctrl* opcode for an example.

## convle

convle — Same as the convolve opcode.

## Description

Same as the *convolve* opcode.

# convolve

`convolve` — Convolves a signal and an impulse response.

## Description

Output is the convolution of signal *ain* and the impulse response contained in *ifilcod*. If more than one output signal is supplied, each will be convolved with the same impulse response. Note that it is considerably more efficient to use one instance of the operator when processing a mono input to create stereo, or quad, outputs.

Note: this opcode can also be written as *convle*.

## Syntax

```
ar1 [, ar2] [, ar3] [, ar4] convolve ain, ifilcod [, ichannel]
```

## Initialization

*ifilcod* -- integer or character-string denoting an impulse response data file. An integer denotes the suffix of a file *convolve.m*; a character string (in double quotes) gives a filename, optionally a full pathname. If not a fullname, the file is sought first in the current directory, then in the one given by the environment variable SADIR (if defined). The data file contains the Fourier transform of an impulse response. Memory usage depends on the size of the data file, which is read and held entirely in memory during computation, but which is shared by multiple calls.

*ichannel* (optional) -- which channel to use from the impulse response data file.

## Performance

*ain* -- input audio signal.

*convolve* implements Fast Convolution. The output of this operator is delayed with respect to the input. The following formulas should be used to calculate the delay:

```
For (1/kr) <= IRdur:  
    Delay = ceil(IRdur * kr) / kr  
For (1/kr) > IRdur:  
    Delay = IRdur * ceil(1/(kr*IRdur))  
Where:  
    kr   = Csound control rate  
    IRdur = duration, in seconds, of impulse response  
    ceil(n) = smallest integer not smaller than n
```

One should be careful to also take into account the initial delay, if any, of the impulse response. For example, if an impulse response is created from a recording, the soundfile may not have the initial delay included. Thus, one should either ensure that the soundfile has the correct amount of zero padding at the start, or, preferably, compensate for this delay in the orchestra (the latter method is more efficient). To compensate for the delay in the orchestra, subtract the initial delay from the result calculated using the above formula(s), when calculating the required delay to introduce into the 'dry' audio path.

For typical applications, such as reverb, the delay will be in the order of 0.5 to 1.5 seconds, or even

longer. This renders the current implementation unsuitable for real time applications. It could conceivably be used for real time filtering however, if the number of taps is small enough.

The author intends to create a higher-level operator at some stage, that would mix the wet & dry signals, using the correct amount of delay automatically.

## Examples

Create frequency domain impulse response file using the *cvalan utility*:

```
csound -Ucvalan 11_44.wav 11_44.cv
```

Determine duration of impulse response. For high accuracy, determine the number of sample frames in the impulse response soundfile, and then compute the duration with:

$$\text{duration} = (\text{sample frames}) / (\text{sample rate of soundfile})$$

This is due to the fact that the *sdinfo utility* only reports the duration to the nearest 10ms. If you have a utility that reports the duration to the required accuracy, then you can simply use the reported value directly.

```
sdinfo 11_44.wav
```

length = 60822 samples, sample rate = 44100

Duration = 60822/44100 = 1.379s.

Determine initial delay, if any, of impulse response. If the impulse response has not had the initial delay removed, then you can skip this step. If it has been removed, then the only way you will know the initial delay is if the information has been provided separately. For this example, let's assume that the initial delay is 60ms (0.06s)

Determine the required delay to apply to the dry signal, to align it with the convolved signal:

If kr = 441:

$1/\text{kr} = 0.0023$ , which is  $\leq \text{IRdur}$  (1.379s), so:

$$\begin{aligned}\text{Delay1} &= \text{ceil}(\text{IRdur} * \text{kr}) / \text{kr} \\ &= \text{ceil}(608.14) / 441 \\ &= 609/441 \\ &= 1.38\text{s}\end{aligned}$$

Accounting for the initial delay:

$$\text{Delay2} = 0.06\text{s}$$

$$\begin{aligned}\text{Total delay} &= \text{delay1} - \text{delay2} \\ &= 1.38 - 0.06 \\ &= 1.32\text{s}\end{aligned}$$

Here is similar example of the convolve opcode. It uses the file *convolve.csd* [examples/convolve.csd].

**Example 134. Example of the convolve opcode.**

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# copyf2array

copyf2array — Copy data from an f-table to a vector.

## Description

The *copyf2array* opcode takes an f-table and copies the contents to a t-var.

## Syntax

```
copyf2array tab, kftbl
```

## Performance

*tab* -- tables for destination.

*kftbl* -- f-tables for source.

## Example

Here is an example of the *copyf2array* opcode. It uses the file *copyf2array.csd* [examples/*copyf2array.csd*].

### Example 136. Example of the copyf2array opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# cosseg

cosseg — Trace a series of line segments between specified points with cosine interpolation.

## Description

Trace a series of line segments between specified points with cosine interpolation.

## Syntax

```
ares cosseg ia, idur1, ib [, idur2] [, ic] [...]
```

```
kres cosseg ia, idur1, ib [, idur2] [, ic] [...]
```

## Initialization

*ia* -- starting value.

*ib*, *ic*, etc. -- value after *durl* seconds, etc.

*idur1* -- duration in seconds of first segment. A zero or negative value will cause all initialization to be skipped.

*idur2*, *idur3*, etc. -- duration in seconds of subsequent segments. A zero or negative value will terminate the initialization process with the preceding point, permitting the last-defined line or curve to be continued indefinitely in performance. The default is zero.

## Performance

These units generate control or audio signals whose values can pass through 2 or more specified points. The sum of *dur* values may or may not equal the instrument's performance time: a shorter performance will truncate the specified pattern, while a longer one will cause the last value to be repeated until the end of the note.

## Examples

Here is an example of the cosseg opcode. It uses the file *cosseg.csd* [examples/cosseg.csd].

### Example 138. Example of the cosseg opcode.

# cossegb

cossegb — Trace a series of line segments between specified absolute points with cosine interpolation.

## Description

Trace a series of line segments between specified absolute points with cosine interpolation.

## Syntax

```
ares cossegb ia, itim1, ib [, itim2] [, ic] [...]
```

```
kres cossegb ia, itim1, ib [, itim2] [, ic] [...]
```

## Initialization

*ia* -- starting value.

*ib*, *ic*, etc. -- value at *tim1* seconds, etc.

*itim1* -- time in seconds of end of first segment. A zero or negative value will cause all initialization to be skipped.

*itim2*, *itim3*, etc. -- time in seconds at the end of subsequent segments.

## Performance

These units generate control or audio signals whose values can pass through 2 or more specified points. The last *tim* value may or may not equal the instrument's performance time: a shorter performance will truncate the specified pattern, while a longer one will cause the last value to be repeated until the end of the note.

## Examples

Here is an example of the cossegb opcode. It uses the file *cossegb.csd* [examples/cossegb.csd].

### Example 139. Example of the cossegb opcode.

# cossegr

**cossegr** — Trace a series of line segments between specified points with cosine interpolation, including a release segment.

## Description

Trace a series of line segments between specified points with cosine interpolation, including a release segment.

## Syntax

```
ares cossegr ia, idur1, ib [, idur2] [, ic] [...], irel, iz  
kres cossegr ia, idur1, ib [, idur2] [, ic] [...], irel, iz
```

## Initialization

*ia* -- starting value.

*ib, ic*, etc. -- value after *dur1* seconds, etc.

*idur1* -- duration in seconds of first segment. A zero or negative value will cause all initialization to be skipped.

*idur2, idur3*, etc. -- duration in seconds of subsequent segments. A zero or negative value will terminate the initialization process with the preceding point, permitting the last-defined line or curve to be continued indefinitely in performance. The default is zero.

*irel, iz* -- duration in seconds and final value of a note releasing segment.

## Performance

These units generate control or audio signals whose values can pass through 2 or more specified points. The sum of *dur* values may or may not equal the instrument's performance time: a shorter performance will truncate the specified pattern, while a longer one will cause the last-defined segment to continue on in the same direction.

*cossegr* is amongst the Csound “r” units that contain a note-off sensor and release time extender. When each senses an event termination or MIDI noteoff, it immediately extends the performance time of the current instrument by *irel* seconds, and sets out to reach the value *iz* by the end of that period (no matter which segment the unit is in). “r” units can also be modified by MIDI noteoff velocities. For two or more extenders in an instrument, extension is by the greatest period.

You can use other pre-made envelopes which start a release segment upon receiving a note off message, like *linenr* and *expsegr*, or you can construct more complex envelopes using *xratim* and *release*. Note that you don't need to use *xratim* if you are using *cossegr*, since the time is extended automatically.

## Examples

Here is an example of the cossegr opcode. It uses the file *cossegr.csd* [examples/cossegr.csd].

### Example 140. Example of the cossegr opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# cps2pch

cps2pch — Converts a pitch-class value into cycles-per-second (Hz) for equal divisions of the octave.

## Description

Converts a pitch-class value into cycles-per-second (Hz) for equal divisions of the octave.

## Syntax

```
icps cps2pch ipch, iequal
```

## Initialization

*ipch* -- Input number of the form 8ve.pc, indicating an 'octave' and which note in the octave.

*iequal* -- If positive, the number of equal intervals into which the 'octave' is divided. Must be less than or equal to 100. If negative, is the number of a table of frequency multipliers.

### Note

1. The following are essentially the same

```
ia = cpspoch(8.02)
ib   cps2pch 8.02, 12
ic   cpsxpcn 8.02, 12, 2, 1.02197503906
```

2. These are opcodes not functions
3. Negative values of *ipch* are allowed.

## Examples

Here is an example of the cps2pch opcode. It uses the file *cps2pch.csd* [examples/cps2pch.csd].

### Example 143. Example of the cps2pch opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# cpsmidi

cpsmidi — Get the note number of the current MIDI event, expressed in cycles-per-second.

## Description

Get the note number of the current MIDI event, expressed in cycles-per-second.

## Syntax

```
icps cpsmidi
```

## Performance

Get the note number of the current MIDI event, expressed in cycles-per-second units, for local processing.

### cpsmidi vs. cpsmidinn

The *cpsmidi* opcode only produces meaningful results in a Midi-activated note (either real-time or from a Midi score with the -F flag). With *cpsmidi*, the Midi note number value is taken from the Midi event that is internally associated with the instrument instance. On the other hand, the *cpsmidinn* opcode may be used in any Csound instrument instance whether it is activated from a Midi event, score event, line event, or from another instrument. The input value for *cpsmidinn* might for example come from a p-field in a textual score or it may have been retrieved from the real-time Midi event that activated the current note using the *notnum* opcode.

## Examples

Here is an example of the *cpsmidi* opcode. It uses the file *cpsmidi.csd* [examples/cpsmidi.csd].

### Example 146. Example of the *cpsmidi* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# cpsmidib

`cpsmidib` — Get the note number of the current MIDI event and modify it by the current pitch-bend value, express it in cycles-per-second.

## Description

Get the note number of the current MIDI event and modify it by the current pitch-bend value, express it in cycles-per-second.

## Syntax

```
icps cpsmidib [irange]
```

```
kcps cpsmidib [irange]
```

## Initialization

*irange* (optional) -- the pitch bend range in semitones.

## Performance

Get the note number of the current MIDI event, modify it by the current pitch-bend value, and express the result in cycles-per-second units. Available as an i-time value or as a continuous k-rate value.

## Examples

Here is an example of the `cpsmidib` opcode. It uses the file `cpsmidib.csd` [examples/cpsmidib.csd].

### Example 147. Example of the `cpsmidib` opcode.

# cpsmidinn

cpsmidinn — Converts a Midi note number value to cycles-per-second.

## Description

Converts a Midi note number value to cycles-per-second.

## Syntax

`cpsmidinn (MidiNoteNumber) (init- or control-rate args only)`

where the argument within the parentheses may be a further expression.

## Performance

*cpsmidinn* is a function that takes an i-rate or k-rate value representing a Midi note number and returns the equivalent frequency value in cycles-per-second (Hertz). This conversion assumes that Middle C is Midi note number 60 and that Middle A is tuned to 440 Hz. Midi note number values are typically integers in the range from 0 to 127 but fractional values or values outside of this range will be interpreted consistently.

### cpsmidinn vs. cpsmidi

The *cpsmidinn* opcode may be used in any Csound instrument instance whether it is activated from a Midi event, score event, line event, or from another instrument. The input value for *cpsmidinn* might for example come from a p-field in a textual score or it may have been retrieved from the real-time Midi event that activated the current note using the *notnum* opcode. You must specify an i-rate or k-rate expression for the Midi note number that is to be converted. On the other hand, the *cpsmidi* opcode only produces meaningful results in a Midi-activated note (either real-time or from a Midi score with the -F flag). With *cpsmidi*, the Midi note number value is taken from the Midi event associated with the instrument instance, and no location or expression for this value may be specified.

*cpsmidinn* and its related opcodes are really *value converters* with a special function of manipulating pitch data.

Data concerning pitch and frequency can exist in any of the following forms:

**Table 6. Pitch and Frequency Values**

| Name                              | Abbreviation |
|-----------------------------------|--------------|
| octave point pitch-class (8ve.pc) | pch          |
| octave point decimal              | oct          |
| cycles per second                 | cps          |
| Midi note number (0-127)          | midinn       |

The first two forms consist of a whole number, representing octave registration, followed by a specially

interpreted fractional part. For *pch*, the fraction is read as two decimal digits representing the 12 equal-tempered pitch classes from .00 for C to .11 for B. For *oct*, the fraction is interpreted as a true decimal fractional part of an octave. The two fractional forms are thus related by the factor 100/12. In both forms, the fraction is preceded by a whole number octave index such that 8.00 represents Middle C, 9.00 the C above, etc. Midi note number values range between 0 and 127 (inclusively) with 60 representing Middle C, and are usually whole numbers. Thus A440 can be represented alternatively by 440 (*cps*), 69 (*midinn*), 8.09 (*pch*), or 8.75 (*oct*). Microtonal divisions of the *pch* semitone can be encoded by using more than two decimal places.

The mnemonics of the pitch conversion units are derived from morphemes of the forms involved, the second morpheme describing the source and the first morpheme the object (result). Thus *cpspch*(8.09) will convert the pitch argument 8.09 to its *cps* (or Hertz) equivalent, giving the value of 440. Since the argument is constant over the duration of the note, this conversion will take place at i-time, before any samples for the current note are produced.

By contrast, the conversion *cpsoct*(8.75 + *k1*) which gives the value of A440 transposed by the octave interval *k1*. The calculation will be repeated every *k*-period since that is the rate at which *k1* varies.

## Note

The conversion from *pch*, *oct*, or *midinn* into *cps* is not a linear operation but involves an exponential process that could be time-consuming when executed repeatedly. Csound now uses a built-in table lookup to do this efficiently, even at audio rates. Because the table index is truncated without interpolation, pitch resolution when using one of these opcodes is limited to 8192 discrete and equal divisions of the octave, and some pitches of the standard 12-tone equally-tempered scale are very slightly mistuned (by at most 0.15 cents).

## Examples

Here is an example of the *cpsmidinn* opcode. It uses the file *cpsmidinn.csd* [examples/cpsmidinn.csd].

### Example 148. Example of the *cpsmidinn* opcode.

# cpsoct

cpsoct — Converts an octave-point-decimal value to cycles-per-second.

## Description

Converts an octave-point-decimal value to cycles-per-second.

## Syntax

`cpsoct (oct) (no rate restriction)`

where the argument within the parentheses may be a further expression.

## Performance

*cpsoct* and its related opcodes are really *value converters* with a special function of manipulating pitch data.

Data concerning pitch and frequency can exist in any of the following forms:

**Table 7. Pitch and Frequency Values**

| Name                              | Abbreviation |
|-----------------------------------|--------------|
| octave point pitch-class (8ve.pc) | pch          |
| octave point decimal              | oct          |
| cycles per second                 | cps          |
| Midi note number (0-127)          | midinn       |

The first two forms consist of a whole number, representing octave registration, followed by a specially interpreted fractional part. For *pch*, the fraction is read as two decimal digits representing the 12 equal-tempered pitch classes from .00 for C to .11 for B. For *oct*, the fraction is interpreted as a true decimal fractional part of an octave. The two fractional forms are thus related by the factor 100/12. In both forms, the fraction is preceded by a whole number octave index such that 8.00 represents Middle C, 9.00 the C above, etc. Midi note number values range between 0 and 127 (inclusively) with 60 representing Middle C, and are usually whole numbers. Thus A440 can be represented alternatively by 440 (*cps*), 69 (*midinn*), 8.09 (*pch*), or 8.75 (*oct*). Microtonal divisions of the *pch* semitone can be encoded by using more than two decimal places.

The mnemonics of the pitch conversion units are derived from morphemes of the forms involved, the second morpheme describing the source and the first morpheme the object (result). Thus *cspch*(8.09) will convert the pitch argument 8.09 to its *cps* (or Hertz) equivalent, giving the value of 440. Since the argument is constant over the duration of the note, this conversion will take place at i-time, before any samples for the current note are produced.

By contrast, the conversion *cpsoct*(8.75 + *k1*) which gives the value of A440 transposed by the octave interval *k1*. The calculation will be repeated every k-period since that is the rate at which *k1* varies.

## Note

The conversion from *pch*, *oct*, or *midinn* into *cps* is not a linear operation but involves an exponential process that could be time-consuming when executed repeatedly. Csound now uses a built-in table lookup to do this efficiently, even at audio rates. Because the table index is truncated without interpolation, pitch resolution when using one of these opcodes is limited to 8192 discrete and equal divisions of the octave, and some pitches of the standard 12-tone equally-tempered scale are very slightly mistuned (by at most 0.15 cents).

## Examples

# cpspch

epspch — Converts a pitch-class value to cycles-per-second.

## Description

Converts a pitch-class value to cycles-per-second.

## Syntax

`cpspch (pch) (init- or control-rate args only)`

where the argument within the parentheses may be a further expression.

## Performance

*cpspch* and its related opcodes are really *value converters* with a special function of manipulating pitch data.

Data concerning pitch and frequency can exist in any of the following forms:

**Table 8. Pitch and Frequency Values**

| Name                              | Abbreviation |
|-----------------------------------|--------------|
| octave point pitch-class (8ve.pc) | pch          |
| octave point decimal              | oct          |
| cycles per second                 | cps          |
| Midi note number (0-127)          | midinn       |

The first two forms consist of a whole number, representing octave registration, followed by a specially interpreted fractional part. For *pch*, the fraction is read as two decimal digits representing the 12 equal-tempered pitch classes from .00 for C to .11 for B. For *oct*, the fraction is interpreted as a true decimal fractional part of an octave. The two fractional forms are thus related by the factor 100/12. In both forms, the fraction is preceded by a whole number octave index such that 8.00 represents Middle C, 9.00 the C above, etc. Midi note number values range between 0 and 127 (inclusively) with 60 representing Middle C, and are usually whole numbers. Thus A440 can be represented alternatively by 440 (*cps*), 69 (*midinn*), 8.09 (*pch*), or 8.75 (*oct*). Microtonal divisions of the *pch* semitone can be encoded by using more than two decimal places.

The mnemonics of the pitch conversion units are derived from morphemes of the forms involved, the second morpheme describing the source and the first morpheme the object (result). Thus *cpspch*(8.09) will convert the pitch argument 8.09 to its *cps* (or Hertz) equivalent, giving the value of 440. Since the argument is constant over the duration of the note, this conversion will take place at i-time, before any samples for the current note are produced.

By contrast, the conversion *cpsoct*(8.75 + *k1*) which gives the value of A440 transposed by the octave interval *k1*. The calculation will be repeated every k-period since that is the rate at which *k1* varies.

## Note

The conversion from *pch*, *oct*, or *midinn* into *cps* is not a linear operation but involves an exponential process that could be time-consuming when executed repeatedly. Csound now uses a built-in table lookup to do this efficiently, even at audio rates. Because the table index is truncated without interpolation, pitch resolution when using one of these opcodes is limited to 8192 discrete and equal divisions of the octave, and some pitches of the standard 12-tone equally-tempered scale are very slightly mistuned (by at most 0.15 cents).

If you need more precision in the calculation, use *cps2pch* or *cpsxpch* instead.

## Examples

Here is an example of the *cpspch* opcode. It uses the file *cpspch.csd* [examples/cpspch.csd].

# cpstmid

`cpstmid` — Get a MIDI note number (allows customized micro-tuning scales).

## Description

This unit is similar to *cpsmidi*, but allows fully customized micro-tuning scales.

## Syntax

```
icps cpstmid ifn
```

## Initialization

*ifn* -- function table containing the parameters (*numgrades*, *interval*, *basefreq*, *basekeymidi*) and the tuning ratios.

## Performance

Init-rate only

*cpsmido* requires five parameters, the first, *ifn*, is the function table number of the tuning ratios, and the other parameters must be stored in the function table itself. The function table *ifn* should be generated by *GEN02*, with normalization inhibited. The first four values stored in this function are:

1. *numgrades* -- the number of grades of the micro-tuning scale
2. *interval* -- the frequency range covered before repeating the grade ratios, for example 2 for one octave, 1.5 for a fifth etc.
3. *basefreq* -- the base frequency of the scale in Hz
4. *basekeymidi* -- the MIDI note number to which *basefreq* is assigned unmodified

After these four values, the user can begin to insert the tuning ratios. For example, for a standard 12 note scale with the base frequency of 261 Hz assigned to the key number 60, the corresponding f-statement in the score to generate the table should be:

```
;      numgrades interval basefreq basekeymidi tuning ratios (equal temp)
f1 0 64 -2 12    2     261     60     1 1.059463094359 1.122462048309 1.189207115003 ..etc...
```

Another example with a 24 note scale with a base frequency of 440 assigned to the key number 48, and a repetition interval of 1.5:

```
;      numgrades interval basefreq basekeymidi tuning-ratios (equal temp)
f1 0 64 -2 24    1.5   440     48     1 1.01 1.02 1.03 ..etc...
```

## Examples

# cpstun

`cpstun` — Returns micro-tuning values at k-rate.

## Description

Returns micro-tuning values at k-rate.

## Syntax

```
kcps cpstun ktrig, kindex, kfn
```

## Performance

*kcps* -- Return value in cycles per second.

*ktrig* -- A trigger signal used to trigger the evaluation.

*kindex* -- An integer number denoting an index of scale.

*kfn* -- Function table containing the parameters (numgrades, interval, basefreq, basekeymidi) and the tuning ratios.

These opcodes are similar to *cpstmid*, but work without necessity of MIDI.

*cpstun* works at k-rate. It allows fully customized micro-tuning scales. It requires a function table number containing the tuning ratios, and some other parameters stored in the function table itself.

*kindex* arguments should be filled with integer numbers expressing the grade of given scale to be converted in cps. In *cpstun*, a new value is evaluated only when *ktrig* contains a non-zero value. The function table *kfn* should be generated by *GEN02* and the first four values stored in this function are parameters that express:

- *numgrades* -- The number of grades of the micro-tuning scale.
- *interval* -- The frequency range covered before repeating the grade ratios, for example 2 for one octave, 1.5 for a fifth etcetera.
- *basefreq* -- The base frequency of the scale in cycles per second.
- *basekey* -- The integer index of the scale to which to assign *basefreq* unmodified.

After these four values, the user can begin to insert the tuning ratios. For example, for a standard 12-grade scale with the base-frequency of 261 cps assigned to the key-number 60, the corresponding f-statement in the score to generate the table should be:

```
;      numgrades    basefreq    tuning-ratios (eq.temp) .....
;           interval     basekey
f1 0 64 -2 12      2       261    60      1   1.059463 1.12246 1.18920 ..etc...
```

Another example with a 24-grade scale with a base frequency of 440 assigned to the key-number 48, and a repetition interval of 1.5:

```
;          numgrades      basefreq      tuning-ratios .....
;          interval      basekey
f1 0 64 -2        24       1.5       440       48      1   1.01   1.02   1.03   ..etc...
```

## Examples

# cpstuni

`cpstuni` — Returns micro-tuning values at init-rate.

## Description

Returns micro-tuning values at init-rate.

## Syntax

```
icps cpstuni index, ifn
```

## Initialization

*icps* -- Return value in cycles per second.

*index* -- An integer number denoting an index of scale.

*ifn* -- Function table containing the parameters (numgrades, interval, basefreq, basekeymidi) and the tuning ratios.

## Performance

These opcodes are similar to *cpstmid*, but work without necessity of MIDI.

*cpstuni* works at init-rate. It allows fully customized micro-tuning scales. It requires a function table number containing the tuning ratios, and some other parameters stored in the function table itself.

The *index* argument should be filled with integer numbers expressing the grade of given scale to be converted in cps. The function table *ifn* should be generated by *GEN02* and the first four values stored in this function are parameters that express:

- *numgrades* -- The number of grades of the micro-tuning scale.
- *interval* -- The frequency range covered before repeating the grade ratios, for example 2 for one octave, 1.5 for a fifth etcetera.
- *basefreq* -- The base frequency of the scale in cycles per second.
- *basekey* -- The integer index of the scale to which to assign *basefreq* unmodified.

After these four values, the user can begin to insert the tuning ratios. For example, for a standard 12-grade scale with the base-frequency of 261 cps assigned to the key-number 60, the corresponding f- statement in the score to generate the table should be:

```
;           numgrades    basefreq      tuning-ratios (eq.temp) .....
;                   interval     basekey
f1 0 64 -2 12      2       261     60      1   1.059463 1.12246 1.18920 ..etc...
```

Another example with a 24-grade scale with a base frequency of 440 assigned to the key-number 48, and a repetition interval of 1.5:

```
;          numgrades      basefreq      tuning-ratios .....
;          interval      basekey
f1 0 64 -2        24       1.5       440       48      1   1.01   1.02   1.03   ..etc...
```

## Examples

Here is an example of the cpstuni opcode. It uses the file *cpstuni.csd* [examples/cpstuni.csd].

### Example 154. Example of the cpstuni opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out    Audio in

# cpsxpch

cpsxpch — Converts a pitch-class value into cycles-per-second (Hz) for equal divisions of any interval.

## Description

Converts a pitch-class value into cycles-per-second (Hz) for equal divisions of any interval. There is a restriction of no more than 100 equal divisions.

## Syntax

```
icps cpsxpch ipch, iequal, irepeat, ibase
```

## Initialization

*ipch* -- Input number of the form 8ve.pc, indicating an 'octave' and which note in the octave.

*iequal* -- if positive, the number of equal intervals into which the 'octave' is divided. Must be less than or equal to 100. If negative, is the number of a table of frequency multipliers.

*irepeat* -- Number indicating the interval which is the 'octave.' The integer 2 corresponds to octave divisions, 3 to a twelfth, 4 is two octaves, and so on. This need not be an integer, but must be positive.

*ibase* -- The frequency which corresponds to pitch 0.0

### Note

1. The following are essentially the same

```
ia = cpspch(8.02)
ib = cps2pch 8.02, 12
ic = cpsxpch 8.02, 12, 2, 1.02197503906
```

2. These are opcodes not functions
3. Negative values of *ipch* are allowed, but not negative *irepeat*, *iequal* or *ibase*.

## Examples

Here is an example of the cpsxpch opcode. It uses the file *cpsxpch.csd* [examples/cpsxpch.csd].

### Example 155. Example of the cpsxpch opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# cpumeter

cpumeter — Reports the usage of cpu either total or per core.

## Description

Reports the usage of cpu either total or per core to monitor how close to max-out the processing is.

## Syntax

```
ktot[,kcpu1, kcpu2,...]cpumeter ifreq
```

## Initialization

*ifreq* is the time in seconds that the meter is refreshed. If this is too low then mainly figures of zero or one hundred occur. A value of 0.1 seems acceptable.

## Performance

*cpumeter* reads the total idle time in the last *ifreq* seconds and reports it as a percentage usage. If more than just *ktot* results are requested these report the same value for individual cores.

## Examples

Here is an example of the cpumeter opcode. It uses the file *cpumeter.csd* [examples/cpumeter.csd].

### Example 158. Example of the cpumeter opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# cpuprc

`cpuprc` — Control allocation of cpu resources on a per-instrument basis, to optimize realtime output.

## Description

Control allocation of cpu resources on a per-instrument basis, to optimize realtime output.

## Syntax

```
cpuprc insnum, ipercent
```

```
cpuprc Sinsname, ipercent
```

## Initialization

*insnum* -- instrument number or string

*Sinsname* -- instrument number or string

*ipercent* -- percent of cpu processing-time to assign. Can also be expressed as a fractional value.

## Performance

`cpuprc` sets the cpu processing-time percent usage of an instrument, in order to avoid buffer underrun in realtime performances, enabling a sort of polyphony threshold. The user must set *ipercent* value for each instrument to be activated in realtime. Assuming that the total theoretical processing time of the cpu of the computer is 100%, this percent value can only be defined empirically, because there are too many factors that contribute to limiting realtime polyphony in different computers.

For example, if *ipercent* is set to 5% for instrument 1, the maximum number of voices that can be allocated in realtime, is 20 ( $5\% * 20 = 100\%$ ). If the user attempts to play a further note while the 20 previous notes are still playing, Csound inhibits the allocation of that note and will display the following warning message:

```
can't allocate last note because it exceeds 100% of cpu time
```

In order to avoid audio buffer underruns, it is suggested to set the maximum number of voices slightly lower than the real processing power of the computer. Sometimes an instrument can require more processing time than normal. If, for example, the instrument contains an oscillator which reads a table that doesn't fit in cache memory, it will be slower than normal. In addition, any program running concurrently in multitasking, can subtract processing power to varying degrees.

At the start, all instruments are set to a default value of *ipercent* = 0.0% (i.e. zero processing time or rather infinite cpu processing-speed). This setting is OK for deferred-time sessions.

All instances of `cpuprc` must be defined in the header section, not in the instrument body.

## Examples

---

Here is an example of the cpuprc opcode. It uses the file *cpuprc.csd* [examples/cpuprc.csd].

# cross2

`cross2` — Cross synthesis using FFT's.

## Description

This is an implementation of cross synthesis using FFT's.

## Syntax

```
ares cross2 ain1, ain2, isize, ioverlap, iwin, kbias
```

## Initialization

*isize* -- This is the size of the FFT to be performed. The larger the size the better the frequency response but a sloppy time response.

*overlap* -- This is the overlap factor of the FFT's, must be a power of two. The best settings are 2 and 4. A big overlap takes a long time to compile.

*iwin* -- This is the function table that contains the window to be used in the analysis. One can use the *GEN20* routine to create this window.

## Performance

*ain1* -- The stimulus sound. Must have high frequencies for best results.

*ain2* -- The modulating sound. Must have a moving frequency response (like speech) for best results.

*kbias* -- The amount of cross synthesis. 1 is the normal, 0 is no cross synthesis.

## Examples

Here is an example of the *cross2* opcode. It uses the file *cross2.csd* [examples/cross2.csd] and *fox.wav* [examples/fox.wav].

### Example 160. Example of the cross2 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# **crossfm**

**crossfm** — Two mutually frequency and/or phase modulated oscillators.

## **Description**

Two oscillators, mutually frequency and/or phase modulated by each other.

## **Syntax**

```
a1, a2 crossfm xfrq1, xfrq2, xndx1, xndx2, kcps, ifn1, ifn2 [, iphs1] [, iphs2]  
  
a1, a2 crossfmi xfrq1, xfrq2, xndx1, xndx2, kcps, ifn1, ifn2 [, iphs1] [, iphs2]  
  
a1, a2 crosspm xfrq1, xfrq2, xndx1, xndx2, kcps, ifn1, ifn2 [, iphs1] [, iphs2]  
  
a1, a2 crossppmi xfrq1, xfrq2, xndx1, xndx2, kcps, ifn1, ifn2 [, iphs1] [, iphs2]  
  
a1, a2 crossfmpm xfrq1, xfrq2, xndx1, xndx2, kcps, ifn1, ifn2 [, iphs1] [, iphs2]  
  
a1, a2 crossfmpmi xfrq1, xfrq2, xndx1, xndx2, kcps, ifn1, ifn2 [, iphs1] [, iphs2]
```

## **Initialization**

*ifn1* -- function table number for oscillator #1. Requires a wrap-around guard point.

*ifn2* -- function table number for oscillator #2. Requires a wrap-around guard point.

*iphs1* (optional, default=0) -- initial phase of waveform in table *ifn1*, expressed as a fraction of a cycle (0 to 1). A negative value will cause phase initialization to be skipped.

*iphs2* (optional, default=0) -- initial phase of waveform in table *ifn2*, expressed as a fraction of a cycle (0 to 1). A negative value will cause phase initialization to be skipped.

## **Performance**

*xfrq1* -- a factor that, when multiplied by the *kcps* parameter, gives the frequency of oscillator #1.

*xfrq2* -- a factor that, when multiplied by the *kcps* parameter, gives the frequency of oscillator #2.

*xndx1* -- the index of the modulation of oscillator #2 by oscillator #1.

*xndx2* -- the index of the modulation of oscillator #1 by oscillator #2.

*kcps* -- a common denominator, in cycles per second, for both oscillators frequencies.

*crossfm* implements a crossed frequency modulation algorithm. The audio-rate output of oscillator #1 is used to modulate the frequency input of oscillator #2 while the audio-rate output of oscillator #2 is used to modulate the frequency input of oscillator #1. This double feedback structure produces a rich set of sounds with some chaotic behaviour. *crossfmi* behaves like *crossfm* except that linear interpolation is used for table lookup.

*crosspm* and *crosspmi* implement cross phase modulation between two oscillators.

*crossfmpm* and *crossfmpmi* implement cross frequency/phase modulation between two oscillators. Oscillator #1 is frequency-modulated by oscillator #2 while oscillator #2 is phase-modulated by oscillator #1.

You can read my *paper* [<http://www.csoundjournal.com/issue12/crossfm.html>] in the Csound Journal for more information.

## Warning

Those opcodes may produce very rich spectra, especially with high modulation indexes, and in some cases foldover aliases may occur if the sampling rate is not high enough. Moreover the audio output may vary in function of the sampling rate, due to the non-linearity of the algorithm. In Csound, two other opcodes have this characteristic: *planet* and *chuap*.

## Examples

Here is an example of the *crossfm* opcode. It uses the file *crossfm.csd* [examples/crossfm.csd].

### Example 161. Example of the *crossfm* opcode.

# crunch

crunch — Semi-physical model of a crunch sound.

## Description

*crunch* is a semi-physical model of a crunch sound. It is one of the PhISEM percussion opcodes. PhISEM (Physically Informed Stochastic Event Modeling) is an algorithmic approach for simulating collisions of multiple independent sound producing objects.

## Syntax

```
ares crunch iamp, idettack [, inum] [, idamp] [, imaxshake]
```

## Initialization

*iamp* -- Amplitude of output. Note: As these instruments are stochastic, this is only a approximation.

*idettack* -- period of time over which all sound is stopped

*inum* (optional) -- The number of beads, teeth, bells, timbrels, etc. If zero, the default value is 7.

*idamp* (optional) -- the damping factor, as part of this equation:

$$\text{damping\_amount} = 0.998 + (\text{idamp} * 0.002)$$

The default *damping\_amount* is 0.99806 which means that the default value of *idamp* is 0.03. The maximum *damping\_amount* is 1.0 (no damping). This means the maximum value for *idamp* is 1.0.

The recommended range for *idamp* is usually below 75% of the maximum value.

*imaxshake* (optional) -- amount of energy to add back into the system. The value should be in range 0 to 1.

## Examples

Here is an example of the *crunch* opcode. It uses the file *crunch.csd* [examples/crunch.csd].

### Example 162. Example of the *crunch* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# ctrl14

`ctrl14` — Allows a floating-point 14-bit MIDI signal scaled with a minimum and a maximum range.

## Description

Allows a floating-point 14-bit MIDI signal scaled with a minimum and a maximum range.

## Syntax

```
idest ctrl14 ichan, ictlno1, ictlno2, imin, imax [, ifn]
```

```
kdest ctrl14 ichan, ictlno1, ictlno2, kmin, kmax [, ifn]
```

## Initialization

*idest* -- output signal

*ichan* -- MIDI channel number (1-16)

*ictlno1* -- most-significant byte controller number (0-127)

*ictlno2* -- least-significant byte controller number (0-127)

*imin* -- user-defined minimum floating-point value of output

*imax* -- user-defined maximum floating-point value of output

*ifn* (optional) -- table to be read when indexing is required. Table must be normalized. Output is scaled according to *imax* and *imin* val.

## Performance

*kdest* -- output signal

*kmin* -- user-defined minimum floating-point value of output

*kmax* -- user-defined maximum floating-point value of output

`ctrl14` (i- and k-rate 14 bit MIDI control) allows a floating-point 14-bit MIDI signal scaled with a minimum and a maximum range. The minimum and maximum values can be varied at k-rate. It can use optional interpolated table indexing. It requires two MIDI controllers as input.

`ctrl14` differs from `midic14` because it can be included in score-oriented instruments without Csound crashes. It needs the additional parameter *ichan* containing the MIDI channel of the controller. MIDI channel is the same for all the controllers used in a single `ctrl14` opcode.

Thanks goes to Rasmus Ekman for pointing out the correct MIDI channel and controller number ranges.

# ctrl21

ctrl21 — Allows a floating-point 21-bit MIDI signal scaled with a minimum and a maximum range.

## Description

Allows a floating-point 21-bit MIDI signal scaled with a minimum and a maximum range.

## Syntax

```
idest ctrl21 ichan, ictlno1, ictlno2, ictlno3, imin, imax [, ifn]
```

```
kdest ctrl21 ichan, ictlno1, ictlno2, ictlno3, kmin, kmax [, ifn]
```

## Initialization

*idest* -- output signal

*ichan* -- MIDI channel number (1-16)

*ictlno1* -- most-significant byte controller number (0-127)

*ictlno2* -- mid-significant byte controller number (0-127)

*ictlno3* -- least-significant byte controller number (0-127)

*imin* -- user-defined minimum floating-point value of output

*imax* -- user-defined maximum floating-point value of output

*ifn* (optional) -- table to be read when indexing is required. Table must be normalized. Output is scaled according to *imax* and *imin* val.

## Performance

*kdest* -- output signal

*kmin* -- user-defined minimum floating-point value of output

*kmax* -- user-defined maximum floating-point value of output

*ctrl21* (i- and k-rate 21 bit MIDI control) allows a floating-point 21-bit MIDI signal scaled with a minimum and a maximum range. Minimum and maximum values can be varied at k-rate. It can use optional interpolated table indexing. It requires three MIDI controllers as input.

*ctrl21* differs from *midic21* because it can be included in score oriented instruments without Csound crashes. It needs the additional parameter *ichan* containing the MIDI channel of the controller. MIDI channel is the same for all the controllers used in a single *ctrl21* opcode.

Thanks goes to Rasmus Ekman for pointing out the correct MIDI channel and controller number ranges.

# ctrl7

`ctrl7` — Allows a floating-point 7-bit MIDI signal scaled with a minimum and a maximum range.

## Description

Allows a floating-point 7-bit MIDI signal scaled with a minimum and a maximum range.

## Syntax

```
idest ctrl7 ichan, ictlno, imin, imax [, ifn]  
  
kdest ctrl7 ichan, ictlno, kmin, kmax [, ifn]  
  
adest ctrl7 ichan, ictlno, kmin, kmax [, ifn] [, icutoff]
```

## Initialization

*idest* -- output signal  
*ichan* -- MIDI channel (1-16)  
*ictlno* -- MIDI controller number (0-127)  
*imin* -- user-defined minimum floating-point value of output  
*imax* -- user-defined maximum floating-point value of output  
*ifn* (optional) -- table to be read when indexing is required. Table must be normalized. Output is scaled according to *imax* and *imin* val.  
*icutoff* (optional) -- low pass filter cut-off frequency for smoothing a-rate output.

## Performance

*kdest, adest* -- output signal  
*kmin* -- user-defined minimum floating-point value of output  
*kmax* -- user-defined maximum floating-point value of output  
  
*ctrl7* (i- and k-rate 7 bit MIDI control) allows a floating-point 7-bit MIDI signal scaled with a minimum and a maximum range. It also allows optional non-interpolated table indexing. Minimum and maximum values can be varied at k-rate.

*ctrl7* differs from *midic7* because it can be included in score-oriented instruments without Csound crashes. It also needs the additional parameter *ichan* containing the MIDI channel of the controller.

The a-rate version of *ctrl7* outputs an a-rate variable, which is low-pass filtered (smoothed). It contains an optional *icutoff* parameter, to set the cutoff frequency for the low-pass filter. The default is 5.

## Examples

---

Here is an example of the `ctrl7` opcode. It uses the file `ctrl7.csd` [examples/ctrl7.csd].

### Example 163. Example of the `ctrl7` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac -M0 ;;;RT audio I/O with MIDI in
;-iadc ;;;uncomment -iadc if RT audio input is needed too
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1 ; expects MIDI controller input on channel 1
; run and move your midi controller to see result

imax = 1
imin = 0
ichan = 1
ictlno = 7

    initc7 1, 7, 1           ; start at max. volume
kamp ctrl7 ichan, ictlno, imin, imax ; controller 7
    printk2 kamp
asig oscil kamp, 220, 1
    outs asig, asig

endin

</CsInstruments>
<CsScore>
f 1 0 4096 10 1

i1 0 20

e
</CsScore>
</CsoundSynthesizer>
```

#### Note

`ctrl7` only outputs k values once the controller is first moved. To set an initial k-value, a call to `initc7` is required. `Ctrlinit` does not work for this purpose.

Thanks goes to Rasmus Ekman for pointing out the correct MIDI channel and controller number ranges.

The a-rate version of *ctrl7* was added in version 5.06

## ctrlinit

ctrlinit — Sets the initial values for a set of MIDI controllers.

## Description

Sets the initial values for a set of MIDI controllers.

## Syntax

```
ctrlinit ichnl, ictlno1, ival1 [, ictlno2] [, ival2] [, ictlno3] \
[, ival3] [...ival32]
```

## Initialization

*ichnl* -- MIDI channel number (1-16)

*ictlno1, ictlno1, etc.* -- MIDI controller numbers (0-127)

*ival1, ival2, etc.* -- initial value for corresponding MIDI controller number

## Performance

Sets the initial values for a set of MIDI controllers.

# cuserrnd

cuserrnd — Continuous USER-defined-distribution RaNDom generator.

## Description

Continuous USER-defined-distribution RaNDom generator.

## Syntax

```
aout cuserrnd kmin, kmax, ktableNum  
  
iout cuserrnd imin, imax, itableNum  
  
kout cuserrnd kmin, kmax, ktableNum
```

## Initialization

*imin* -- minimum range limit

*imax* -- maximum range limit

*itableNum* -- number of table containing the random-distribution function. Such table is generated by the user. See GEN40, GEN41, and GEN42. The table length does not need to be a power of 2

## Performance

*ktableNum* -- number of table containing the random-distribution function. Such table is generated by the user. See GEN40, GEN41, and GEN42. The table length does not need to be a power of 2

*kmin* -- minimum range limit

*kmax* -- maximum range limit

*cuserrnd* (continuous user-defined-distribution random generator) generates random values according to a continuous random distribution created by the user. In this case the shape of the distribution histogram can be drawn or generated by any GEN routine. The table containing the shape of such histogram must then be translated to a distribution function by means of GEN40 (see GEN40 for more details). Then such function must be assigned to the XtableNum argument of cuserrnd. The output range can then be rescaled according to the Xmin and Xmax arguments. *cuserrnd* linearly interpolates between table elements, so it is not recommended for discrete distributions (GEN41 and GEN42).

For a tutorial about random distribution histograms and functions see:

- D. Lorrain. "A panoply of stochastic cannons". In C. Roads, ed. 1989. Music machine. Cambridge, Massachusetts: MIT press, pp. 351 - 379.

## Examples

Here is an example of the cuserrnd opcode. It uses the file *cuserrnd.csd* [examples/cuserrnd.csd].

**Example 164. Example of the `cuserrnd` opcode.**

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# dam

dam — A dynamic compressor/expander.

## Description

This opcode dynamically modifies a gain value applied to the input sound *ain* by comparing its power level to a given threshold level. The signal will be compressed/expanded with different factors regarding that it is over or under the threshold.

## Syntax

```
ares dam asig, kthreshold, icomp1, icomp2, irtime, iftime
```

## Initialization

*icomp1* -- compression ratio for upper zone.

*icomp2* -- compression ratio for lower zone

*irtime* -- gain rise time in seconds. Time over which the gain factor is allowed to raise of one unit.

*iftime* -- gain fall time in seconds. Time over which the gain factor is allowed to decrease of one unit.

## Performance

*asig* -- input signal to be modified

*kthreshold* -- level of input signal which acts as the threshold. Can be changed at k-time (e.g. for ducking)

Note on the compression factors: A compression ratio of one leaves the sound unchanged. Setting the ratio to a value smaller than one will compress the signal (reduce its volume) while setting the ratio to a value greater than one will expand the signal (augment its volume).

## Examples

Because the results of the *dam* opcode can be subtle, I recommend looking at them in a graphical audio editor program like *audacity*. *audacity* is available for Linux, Windows, and the MacOS and may be downloaded from <http://audacity.sourceforge.net> [<http://audacity.sourceforge.net/>].

Here is an example of the *dam* opcode. It uses the file *dam.csd* [examples/dam.csd], and *beats.wav* [examples/beats.wav].

### Example 165. An example of the dam opcode compressing an audio signal.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
```

```
; Select audio/midi flags here according to platform
-odac    ;;;RT audio out
;-iadc   ;;;uncomment -iadc if RT audio input is needed too
; For Non-realtime output leave only the line below:
; -o dam.wav -W ;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1 ;normal audio
asig diskin2 "beats.wav", 1, 0, 1
    outs asig, asig
endin

instr 2 ; compressed audio
kthreshold = 0.2
icomp1 = 0.8
icomp2 = 0.2
irtime = 0.01
iftime = 0.5
asig diskin2 "beats.wav", 1, 0, 1
asig dam asig, kthreshold, icomp1, icomp2, irtime, iftime
    outs asig, asig
endin

</CsInstruments>
<CsScore>

i 1 0 2
i 2 2.5 8.5

e
</CsScore>
</CsoundSynthesizer>
```

This example compresses the audio file “beats.wav”. You should hear a drum pattern repeat twice. The second time, the sound should be quieter (compressed) than the first.

Here is another example of the dam opcode. It uses the file *dam\_expanded.csd* [examples/*dam\_expanded.csd*], and *beats.wav* [examples/*beats.wav*].

### Example 166. An example of the dam opcode expanding an audio signal.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac    ;;;RT audio out
;-iadc   ;;;uncomment -iadc if RT audio input is needed too
; For Non-realtime output leave only the line below:
; -o dam_expanded.wav -W ;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1
asig diskin2 "beats.wav", 1, 0, 1
    outs asig, asig
endin

instr 2 ;expanded audio
```

```
kthreshold = .5
icomp1 = 2
icomp2 = 3
irtime = 0.01
iftime = 0.1

asig diskin2 "beats.wav", 1, 0, 1
asig dam asig, kthreshold, icomp1, icomp2, irtime, iftime
      outs asig*.2, asig*.2; adjust volume of expanded beat

endin

</CsInstruments>
<CsScore>

i 1 0 2
i 2 2.5 6.5

e
</CsScore>
</CsoundSynthesizer>
```

This example expands the audio file “beats.wav”. You should hear a drum pattern repeat twice. The second time, the sound should be louder (expanded) than the first. To prevent distortion the volume of the signal has been lowered.

# date

date — Returns the number seconds since a base date.

## Description

Returns the number seconds since a base date, using the operating system's clock. The base is 1 January 1970 for Csound using doubles, and 1 January 2010 for versions using floats.

## Syntax

```
ir date
```

## Initialization

*ir* -- value at i-time, of the system clock in seconds since the start of the epoch.

Note that the base date was originally 1970 but since version 5.14 it has been changed as single precision floating point numbers are insufficient to indicate changes.

## Examples

Here is an example of the date opcode. It uses the file *date.csd* [examples/date.csd].

### Example 167. Example of the date opcode.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out  Audio in
-odac      -iadc    ;;;RT audio I/O

# db

db — Returns the amplitude equivalent for a given decibel amount.

## Description

Returns the amplitude equivalent for a given decibel amount. This opcode is the same as *ampdb*.

## Syntax

`db(x)`

This function works at a-rate, i-rate, and k-rate.

## Initialization

*x* -- a value expressed in decibels.

## Performance

Returns the amplitude for a given decibel amount.

## Examples

Here is an example of the db opcode. It uses the file *db.csd* [examples/db.csd].

### Example 169. Example of the db opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# dbfsamp

dbfsamp — Returns the decibel equivalent of the raw amplitude  $x$ , relative to full scale amplitude.

## Description

Returns the decibel equivalent of the raw amplitude  $x$ , relative to full scale amplitude. Full scale is assumed to be 16 bit. New in Csound version 4.10.

## Syntax

```
dbfsamp(x)  (init-rate or control-rate args only)
```

## Examples

Here is an example of the dbfsamp opcode. It uses the file *dbfsamp.csd* [examples/dbfsamp.csd].

### Example 171. Example of the dbfsamp opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac      ;;;RT audio out
;-iadc     ;;;uncomment -iadc if RT audio input is needed too
; For Non-realtime output leave only the line below:
;-o dbfsamp.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2

instr 1
iamp = p4
idb = dbfsamp(iamp)
print idb

# dcblock

dcblock — A DC blocking filter.

## Description

Implements the DC blocking filter

$$Y[i] = X[i] - X[i-1] + (igain * Y[i-1])$$

Based on work by Perry Cook.

## Syntax

```
ares dcblock ain [, igain]
```

## Initialization

*igain* -- the gain of the filter, which defaults to 0.99

## Performance

*ain* -- audio signal input

### Note

The new *dcblock2* opcode is an improved method of removing DC from an audio signal.

## Examples

The result can be viewed in a graphical audio editor program like *audacity*. *audacity* is available for Linux, Windows, and the MacOS and may be downloaded from <http://audacity.sourceforge.net> [<http://audacity.sourceforge.net/>].

Here is an example of the *dcblock* opcode. It uses the file *dcblock.csd* [examples/dcblock.csd], and *beats.wav* [examples/beats.wav].

### Example 172. Example of the dcblock opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# dcblock2

dcblock2 — A DC blocking filter.

## Description

Implements a DC blocking filter with improved DC attenuation.

## Syntax

```
ares dcblock2 ain [, iorder] [, iskip]
```

## Initialization

*iorder* -- filter order, minimum 4th order, defaults to 128.

*iskip* -- set to 1 to skip initialization (defaults to 0).

## Performance

*ares* -- filtered audio signal

*ain* -- input audio signal

### Note

Using a value for *iorder* less than *ksmps* will not reduce DC offset efficiently.

## Examples

The result can be viewed in a graphical audio editor program like *audacity*. *audacity* is available for Linux, Windows, and the MacOS and may be downloaded from <http://audacity.sourceforge.net> [<http://audacity.sourceforge.net/>].

Here is an example of the dcblock2 opcode. It uses the file *dcblock2.csd* [examples/dcblock2.csd], and *beats.wav* [examples/beats.wav].

### Example 173. Example of the dcblock2 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# dconv

*dconv* — A direct convolution opcode.

## Description

A direct convolution opcode.

## Syntax

```
ares dconv asig, isize, ifn
```

## Initialization

*isize* -- the size of the convolution buffer to use. If the buffer size is smaller than the size of *ifn*, then only the first *isize* values will be used from the table.

*ifn* -- table number of a stored function containing the impulse response for convolution.

## Performance

Rather than the analysis/resynthesis method of the *convolve* opcode, *dconv* uses direct convolution to create the result. For small tables it can do this quite efficiently, however larger table require much more time to run. *dconv* does (*isize* \* *ksmps*) multiplies on every k-cycle. Therefore, reverb and delay effects are best done with other opcodes (unless the times are short).

*dconv* was designed to be used with time varying tables to facilitate new realtime filtering capabilities.

## Examples

Here is an example of the *dconv* opcode. It uses the file *dconv.csd* [examples/dconv.csd].

### Example 174. Example of the dconv opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# delay

`delay` — Delays an input signal by some time interval.

## Description

A signal can be read from or written into a delay path, or it can be automatically delayed by some time interval.

## Syntax

```
ares delay asig, idlt [, iskip]
```

## Initialization

*idlt* -- requested delay time in seconds. This can be as large as available memory will permit. The space required for *n* seconds of delay is  $4n * sr$  bytes. It is allocated at the time the instrument is first initialized, and returned to the pool at the end of a score section.

*iskip* (optional, default=0) -- initial disposition of delay-loop data space (see *reson*). The default value is 0.

## Performance

*asig* -- audio signal

*delay* is a composite of *delayr* and *delayw*, both reading from and writing into its own storage area. It can thus accomplish signal time-shift, although modified feedback is not possible. There is no minimum delay period.

## Examples

Here is an example of the *delay* opcode. It uses the file *delay.csd* [examples/delay.csd].

### Example 175. Example of the *delay* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# delay1

delay1 — Delays an input signal by one sample.

## Description

Delays an input signal by one sample.

## Syntax

```
ares delay1 asig [, iskip]
```

## Initialization

*iskip* (optional, default=0) -- initial disposition of delay-loop data space (see *reson*). The default value is 0.

## Performance

*delay1* is a special form of delay that serves to delay the audio signal *asig* by just one sample. It is thus functionally equivalent to the *delay* opcode but is more efficient in both time and space. This unit is particularly useful in the fabrication of generalized non-recursive filters.

## Examples

Here is an example of the delay and delay1 opcodes. It uses the file *delay1.csd* [examples/delay1.csd].

### Example 176. Example of the delay1 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# delayk

delayk — Delays an input signal by some time interval.

## Description

k-rate delay opcodes

## Syntax

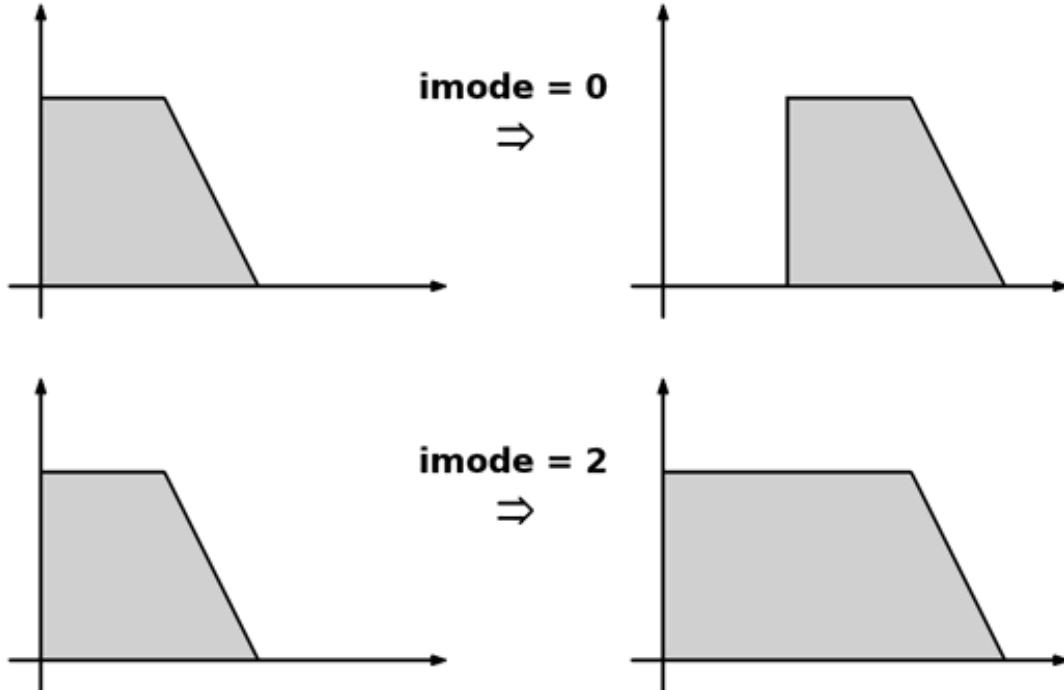

```
kr delayk    ksig, idel[, imode]
```

```
kr vdel_k    ksig, kdel, imdel[, imode]
```

## Initialization

*idel* -- delay time (in seconds) for delayk. It is rounded to the nearest integer multiple of a k-cycle (i.e. 1/kr).

*imode* -- sum of 1 for skipping initialization (e.g. in tied notes) and 2 for holding the first input value during the initial delay, instead of outputting zero. This is mainly of use when delaying envelopes that do not start at zero.

*imdel* -- maximum delay time for vdel\_k, in seconds.

## Performance

---

*kr* -- the output signal. Note: neither of the opcodes interpolate the output.

*ksig* -- the input signal.

*kdel* -- delay time (in seconds) for vdel\_k. It is rounded to the nearest integer multiple of a k-cycle (i.e. 1/kr).

## Examples

Here is an example of the delayk opcode. It uses the file *delayk.csd* [examples/delayk.csd].

### Example 177. Example of the delayk opcode.

# delayr

delayr — Reads from an automatically established digital delay line.

## Description

Reads from an automatically established digital delay line.

## Syntax

```
ares delayr idlt [, iskip]
```

## Initialization

*idlt* -- requested delay time in seconds. This can be as large as available memory will permit. The space required for *n* seconds of delay is  $4n * sr$  bytes. It is allocated at the time the instrument is first initialized, and returned to the pool at the end of a score section.

*iskip* (optional, default=0) -- initial disposition of delay-loop data space (see *reson*). The default value is 0.

## Performance

*delayr* reads from an automatically established digital delay line, in which the signal retrieved has been resident for *idlt* seconds. This unit must be paired with and precede an accompanying *delayw* unit. Any other Csound statements can intervene.

## Examples

Here is an example of the *delayr* opcode. It uses the file *delayr.csd* [examples/delayr.csd].

### Example 178. Example of the *delayr* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# delayw

delayw — Writes the audio signal to a digital delay line.

## Description

Writes the audio signal to a digital delay line.

## Syntax

```
delayw asig
```

## Performance

*delayw* writes *asig* into the delay area established by the preceding *delayr* unit. Viewed as a pair, these two units permit the formation of modified feedback loops, etc. However, there is a lower bound on the value of *idlt*, which must be at least 1 control period (or  $1/kr$ ).

## Examples

Here is an example of the *delayw* opcode. It uses the file *delayw.csd* [examples/delayw.csd].

### Example 179. Example of the delayw opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

*delay, delayI, delayr*

# deltap

deltap — Taps a delay line at variable offset times.

## Description

Tap a delay line at variable offset times.

## Syntax

```
ares deltap kdlr
```

## Performance

*kdlr* -- specifies the tapped delay time in seconds. Each can range from 1 control period to the full delay time of the read/write pair; however, since there is no internal check for adherence to this range, the user is wholly responsible. Each argument can be a constant, a variable, or a time-varying signal.

*deltap* extracts sound by reading the stored samples directly.

This opcode can tap into a *delayr/delayw* pair, extracting delayed audio from the *idlt* seconds of stored sound. There can be any number of *deltap* and/or *deltapi* units between a read/write pair. Each receives an audio tap with no change of original amplitude.

This opcode can provide multiple delay taps for arbitrary delay path and feedback networks. They can deliver either constant-time or time-varying taps, and are useful for building chorus effects, harmonizers, and Doppler shifts. Constant-time delay taps (and some slowly changing ones) do not need interpolated readout; they are well served by *deltap*. Medium-paced or fast varying dlt's, however, will need the extra services of *deltapi*.

*delayr/delayw* pairs may be interleaved. To associate a delay tap unit with a specific *delayr* unit, it not only has to be located between that *delayr* and the appropriate *delayw* unit, but must also precede any following *delayr* units. See Example 2. (This feature added in Csound version 3.57 by Jens Groh and John ffitch).

*N.B.* k-rate delay times are not internally interpolated, but rather lay down stepped time-shifts of audio samples; this will be found quite adequate for slowly changing tap times. For medium to fast-paced changes, however, one should provide a higher resolution audio-rate timeshift as input.

## Examples

### Example 180. deltap example #1

```
asource buzz 1, 440, 20, 1
atime linseg 1, p3/2,.01, p3/2,1 ; trace a distance in secs
ampfac = 1/atime/atime ; and calc an amp factor
adump delayr 1 ; set maximum distance
amove deltapi atime ; move sound source past
                    ; the listener
                    ; move sound source past
out delayw asource
                    ; the listener
                    ; move sound source past
out amove * ampfac
```

### Example 181. deltap example #2

```
ainput1 = .....
ainput2 = .....
kdlyt1 = .....
kdlyt2 = .....

;Read delayed signal, first delayr instance:
adump  delayr 4.0
adly1  deltap  kdlyt1      ; associated with first delayr instance

;Read delayed signal, second delayr instance:
adump  delayr 4.0
adly2  deltap  kdlyt2      ; associated with second delayr instance

;Do some cross-coupled manipulation:
afdbk1 = 0.7 * adly1 + 0.7 * adly2 + ainput1
afdbk2 = -0.7 * adly1 + 0.7 * adly2 + ainput2

;Feed back signal, associated with first delayr instance:
delayw afdbk1

;Feed back signal, associated with second delayr instance:
delayw afdbk2
outs   adly1, adly2
```

Here is yet another example of the deltap opcode. It uses the file *deltap.csd* [examples/deltap.csd].

### Example 182. Example of the deltap opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# deltap3

deltap — Taps a delay line at variable offset times, uses cubic interpolation.

## Description

Taps a delay line at variable offset times, uses cubic interpolation.

## Syntax

```
ares deltap3 xdlt
```

## Performance

*xdlt* -- specifies the tapped delay time in seconds. Each can range from 1 control period to the full delay time of the read/write pair; however, since there is no internal check for adherence to this range, the user is wholly responsible. Each argument can be a constant, a variable, or a time-varying signal; the *xdlt* argument in *deltap3* implies that an audio-varying delay is permitted there.

*deltap3* is experimental, and uses cubic interpolation. (New in Csound version 3.50.)

This opcode can tap into a *delayr/delayw* pair, extracting delayed audio from the *idlt* seconds of stored sound. There can be any number of *deltap* and/or *deltapi* units between a read/write pair. Each receives an audio tap with no change of original amplitude.

This opcode can provide multiple delay taps for arbitrary delay path and feedback networks. They can deliver either constant-time or time-varying taps, and are useful for building chorus effects, harmonizers, and Doppler shifts. Constant-time delay taps (and some slowly changing ones) do not need interpolated readout; they are well served by *deltap*. Medium-paced or fast varying dlt's, however, will need the extra services of *deltapi*.

*delayr/delayw* pairs may be interleaved. To associate a delay tap unit with a specific *delayr* unit, it not only has to be located between that *delayr* and the appropriate *delayw* unit, but must also precede any following *delayr* units. See Example 2. (This feature added in Csound version 3.57 by Jens Groh and John ffitch).

*N.B.* k-rate delay times are not internally interpolated, but rather lay down stepped time-shifts of audio samples; this will be found quite adequate for slowly changing tap times. For medium to fast-paced changes, however, one should provide a higher resolution audio-rate timeshift as input.

## Examples

### Example 183. deltap example #1

```
asource  buzz      1, 440, 20, 1
atime    linseg    1, p3/2,.01, p3/2,1 ; trace a distance in secs
ampfac   =         1/atime/atime      ; and calc an amp factor
adump    delayr    1                   ; set maximum distance
amove    deltapi   atime             ; move sound source past
          delayw    asource           ; the listener
          out       amove * ampfac
```

### Example 184. deltap example #2

```
ainput1 = .....
ainput2 = .....
kdlyt1 = .....
kdlyt2 = .....

;Read delayed signal, first delayr instance:
adump  delyr 4.0
adly1  deltap kdlyt1      ; associated with first delayr instance

;Read delayed signal, second delayr instance:
adump  delyr 4.0
adly2  deltap kdlyt2      ; associated with second delayr instance

;Do some cross-coupled manipulation:
afdbk1 = 0.7 * adly1 + 0.7 * adly2 + ainput1
afdbk2 = -0.7 * adly1 + 0.7 * adly2 + ainput2

;Feed back signal, associated with first delayr instance:
delayw afdbk1

;Feed back signal, associated with second delayr instance:
delayw afdbk2
outs    adly1, adly2
```

Here is yet another example of the deltap3 opcode. It uses the file *deltap3.csd* [examples/deltap3.csd].

# deltapi

deltapi — Taps a delay line at variable offset times, uses interpolation.

## Description

Taps a delay line at variable offset times, uses interpolation.

## Syntax

```
ares deltapi xdlt
```

## Performance

*xdlt* -- specifies the tapped delay time in seconds. Each can range from 1 control period to the full delay time of the read/write pair; however, since there is no internal check for adherence to this range, the user is wholly responsible. Each argument can be a constant, a variable, or a time-varying signal; the *xdlt* argument in *deltapi* implies that an audio-varying delay is permitted there.

*deltapi* extracts sound by interpolated readout. By interpolating between adjacent stored samples *deltapi* represents a particular delay time with more accuracy, but it will take about twice as long to run.

This opcode can tap into a *delayr/delayw* pair, extracting delayed audio from the *idlt* seconds of stored sound. There can be any number of *deltap* and/or *deltapi* units between a read/write pair. Each receives an audio tap with no change of original amplitude.

This opcode can provide multiple delay taps for arbitrary delay path and feedback networks. They can deliver either constant-time or time-varying taps, and are useful for building chorus effects, harmonizers, and Doppler shifts. Constant-time delay taps (and some slowly changing ones) do not need interpolated readout; they are well served by *deltap*. Medium-paced or fast varying dlt's, however, will need the extra services of *deltapi*.

*delayr/delayw* pairs may be interleaved. To associate a delay tap unit with a specific *delayr* unit, it not only has to be located between that *delayr* and the appropriate *delayw* unit, but must also precede any following *delayr* units. See Example 2. (This feature added in Csound version 3.57 by Jens Groh and John ffitch).

*N.B.* k-rate delay times are not internally interpolated, but rather lay down stepped time-shifts of audio samples; this will be found quite adequate for slowly changing tap times. For medium to fast-paced changes, however, one should provide a higher resolution audio-rate timeshift as input.

## Examples

### Example 186. deltap example #1

```
asource  buzz      1, 440, 20, 1
atime    linseg    1, p3/2,.01, p3/2,1 ; trace a distance in secs
ampfac   =         1/atime/atime      ; and calc an amp factor
adump    delayr    1                   ; set maximum distance
amove    deltapi   atime             ; move sound source past
                                delayw   asource          ; the listener
```

```
out      amove * ampfac
```

### Example 187. deltap example #2

```
ainput1 = .....
ainput2 = .....
kdlyt1 = .....
kdlyt2 = .....

;Read delayed signal, first delayr instance:
adump  delayr 4.0
adly1  deltap  kdlyt1      ; associated with first delayr instance

;Read delayed signal, second delayr instance:
adump  delayr 4.0
adly2  deltap  kdlyt2      ; associated with second delayr instance

;Do some cross-coupled manipulation:
afdbk1 = 0.7 * adly1 + 0.7 * adly2 + ainput1
afdbk2 = -0.7 * adly1 + 0.7 * adly2 + ainput2

;Feed back signal, associated with first delayr instance:
delayw afdbk1

;Feed back signal, associated with second delayr instance:
delayw afdbk2
outs   adly1, adly2
```

Here is yet another example of the deltapi opcode. It uses the file *deltapi.csd* [examples/deltapi.csd].

# deltapn

deltapn — Taps a delay line at variable offset times.

## Description

Tap a delay line at variable offset times.

## Syntax

```
ares deltapn xnumsamps
```

## Performance

*xnumsamps* -- specifies the tapped delay time in number of samples. Each can range from 1 control period to the full delay time of the read/write pair; however, since there is no internal check for adherence to this range, the user is wholly responsible. Each argument can be a constant, a variable, or a time-varying signal.

*deltapn* is identical to *deltapi*, except delay time is specified in number of samples, instead of seconds (Hans Mikelson).

This opcode can tap into a *delayr/delayw* pair, extracting delayed audio from the *idlt* seconds of stored sound. There can be any number of *deltap* and/or *deltapi* units between a read/write pair. Each receives an audio tap with no change of original amplitude.

This opcode can provide multiple delay taps for arbitrary delay path and feedback networks. They can deliver either constant-time or time-varying taps, and are useful for building chorus effects, harmonizers, and Doppler shifts. Constant-time delay taps (and some slowly changing ones) do not need interpolated readout; they are well served by *deltap*. Medium-paced or fast varying dlt's, however, will need the extra services of *deltapi*.

*delayr/delayw* pairs may be interleaved. To associate a delay tap unit with a specific *delayr* unit, it not only has to be located between that *delayr* and the appropriate *delayw* unit, but must also precede any following *delayr* units. See Example 2. (This feature added in Csound version 3.57 by Jens Groh and John ffitch).

*N.B.* k-rate delay times are not internally interpolated, but rather lay down stepped time-shifts of audio samples; this will be found quite adequate for slowly changing tap times. For medium to fast-paced changes, however, one should provide a higher resolution audio-rate timeshift as input.

## Examples

Here is an example of the *deltapn* opcode. It uses the file *deltapn.csd* [examples/deltapn.csd].

*deltap, deltap3, deltapi*

# deltapx

*deltapx* — Read from or write to a delay line with interpolation.

## Description

*deltapx* is similar to *deltapi* or *deltap3*. However, it allows higher quality interpolation. This opcode can read from and write to a *delayr/delayw* delay line with interpolation.

## Syntax

```
aout deltapx adel, iwsiz
```

## Initialization

*iwsiz* -- interpolation window size in samples. Allowed values are integer multiples of 4 in the range 4 to 1024. *iwsiz* = 4 uses cubic interpolation. Increasing *iwsiz* improves sound quality at the expense of CPU usage, and minimum delay time.

## Performance

*aout* -- Output signal.

*adel* -- Delay time in seconds.

```
a1      delayr    idlr
a1      deltapxw a2, adl1, iws1
a3      deltapx    adl2, iws2
a3      deltapxw a4, adl3, iws3
a5      delayw   a5
```

Minimum and maximum delay times:

|   |  |
|---|--|
| $idlr \geq 1/kr$  | Delay line length                            |
| $adl1 \geq (iws1/2)/sr$<br>$adl1 \leq idlr - (1 + iws1/2)/sr$   | Write before read<br>(allows shorter delays) |
| $adl2 \geq 1/kr + (iws2/2)/sr$<br>$adl2 \leq idlr - (1 + iws2/2)/sr$<br>$adl2 \geq adl1 + (iws1 + iws2) / (2*sr)$<br>$adl2 \geq 1/kr + adl3 + (iws2 + iws3) / (2*sr)$ | Read time                                    |
| $adl3 \geq (iws3/2)/sr$<br>$adl3 \leq idlr - (1 + iws3/2)/sr$   | Write after read<br>(allows feedback)        |

# deltapxw

`deltapxw` — Mixes the input signal to a delay line.

## Description

`deltapxw` mixes the input signal to a delay line. This opcode can be mixed with reading units (`deltap`, `deltapn`, `deltapi`, `deltap3`, and `deltapx`) in any order; the actual delay time is the difference of the read and write time. This opcode can read from and write to a `delay/delayw` delay line with interpolation.

## Syntax

```
deltapxw ain, adel, iwsiz
```

## Initialization

*iwsiz* -- interpolation window size in samples. Allowed values are integer multiplies of 4 in the range 4 to 1024. *iwsiz* = 4 uses cubic interpolation. Increasing *iwsiz* improves sound quality at the expense of CPU usage, and minimum delay time.

## Performance

*ain* -- Input signal.

*adel* -- Delay time in seconds.

```
a1      delayr    idlr
       deltaxw  a2, adl1, iws1
a3      deltaxp  adl2, iws2
       deltaxw  a4, adl3, iws3
       delayw   a5
```

Minimum and maximum delay times:

|  |                         |
|--|-------------------------|
| idlr >= 1/kr                                 | Delay line length       |
| adl1 >= (iws1/2)/sr                          | Write before read       |
| adl1 <= idlr - (1 + iws1/2)/sr               | (allows shorter delays) |
| adl2 >= 1/kr + (iws2/2)/sr                   | Read time               |
| adl2 <= idlr - (1 + iws2/2)/sr               |                         |
| adl2 >= adl1 + (iws1 + iws2) / (2*sr)        |                         |
| adl2 >= 1/kr + adl3 + (iws2 + iws3) / (2*sr) |                         |
| adl3 >= (iws3/2)/sr                          | Write after read        |
| adl3 <= idlr - (1 + iws3/2)/sr               | (allows feedback)       |

## Note

Window sizes for opcodes other than *deltapx* are: *deltap*, *deltapn*: 1, *deltapi*: 2 (linear), *deltap3*: 4 (cubic)

# denorm

denorm — Mixes low level noise to a list of a-rate signals

## Description

Mixes low level (~1e-20 for floats, and ~1e-56 for doubles) noise to a list of a-rate signals. Can be used before IIR filters and reverbs to avoid denormalized numbers which may otherwise result in significantly increased CPU usage.

## Syntax

```
denorm a1[, a2[, a3[, ... ]]]
```

## Performance

*a1[, a2[, a3[, ... ]]]* -- signals to mix noise with

Some processor architectures (particularly Pentium IVs) are very slow at processing extremely small numbers. These small numbers can appear as a result of some decaying feedback process like reverb and IIR filters. Low level noise can be added so that very small numbers are never reached, and they are 'absorbed' by this 'noise floor'.

If CPU usage goes to 100% at the end of reverb tails, or you get audio glitches in processes that shouldn't use too much CPU, using *denorm* before the culprit opcode or process might solve the problem.

## Examples

Here is an example of the denorm opcode. It uses the file *denorm.csd* [examples/denorm.csd].

### Example 192. Example of the denorm opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# diff

diff — Modify a signal by differentiation.

## Description

Modify a signal by differentiation.

## Syntax

```
ares diff asig [, iskip]
```

```
kres diff ksig [, iskip]
```

## Initialization

*iskip* (optional) -- initial disposition of internal save space (see *reson*). The default value is 0.

## Performance

*integ* and *diff* perform integration and differentiation on an input control signal or audio signal. Each is the converse of the other, and applying both will reconstruct the original signal. Since these units are special cases of low-pass and high-pass filters, they produce a scaled (and phase shifted) output that is frequency-dependent. Thus *diff* of a sine produces a cosine, with amplitude  $2 * \pi * \text{Hz} / \text{sr}$  that of the original (for each component partial); *integ* will inversely affect the magnitudes of its component inputs. With this understanding, these units can provide useful signal modification.

## Examples

Here is an example of the diff opcode. It uses the file *diff.csd* [examples/diff.csd].

### Example 193. Example of the diff opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# diskgrain

diskgrain — Synchronous granular synthesis, using a soundfile as source.

## Description

*diskgrain* implements synchronous granular synthesis. The source sound for the grains is obtained by reading a soundfile containing the samples of the source waveform.

## Syntax

```
asig diskgrain Sfilename, kamp, kfreq, kpitch, kgrsize, kprate, \
      ifun, iolaps [,imaxgrsize , ioffset]
```

## Initialization

*Sfilename* -- source soundfile.

*ifun* -- grain envelope function table.

*iolaps* -- maximum number of overlaps,  $\text{max}(\text{kfreq}) * \text{max}(\text{kgrsize})$ . Estimating a large value should not affect performance, but exceeding this value will probably have disastrous consequences.

*imaxgrsize* -- max grain size in secs (default 1.0).

*ioffset* -- start offset in secs from beginning of file (default: 0).

## Performance

*kamp* -- amplitude scaling

*kfreq* -- frequency of grain generation, or density, in grains/sec.

*kpitch* -- grain pitch scaling (1=normal pitch, < 1 lower, > 1 higher; negative, backwards)

*kgrsize* -- grain size in secs.

*kprate* -- readout pointer rate, in grains. The value of 1 will advance the reading pointer 1 grain ahead in the source table. Larger values will time-compress and smaller values will time-expand the source signal. Negative values will cause the pointer to run backwards and zero will freeze it.

The grain generator has full control of frequency (grains/sec), overall amplitude, grain pitch (a sampling increment) and grain size (in secs), both as fixed or time-varying (signal) parameters. An extra parameter is the grain pointer speed (or rate), which controls which position the generator will start reading samples in the file for each successive grain. It is measured in fractions of grain size, so a value of 1 (the default) will make each successive grain read from where the previous grain should finish. A value of 0.5 will make the next grain start at the midway position from the previous grain start and finish, etc.. A value of 0 will make the generator read always from a fixed position (wherever the pointer was last at). A negative value will decrement pointer positions. This control gives extra flexibility for creating timescale modifications in the resynthesis.

*Diskgrain* will generate any number of parallel grain streams (which will depend on grain density/frequency), up to the olaps value (default 100). The number of streams (overlapped grains) is determined

by grainsize\*grain\_freq. More grain overlaps will demand more calculations and the synthesis might not run in realtime (depending on processor power).

*Diskgrain* can simulate FOF-like formant synthesis, provided that a suitable shape is used as grain envelope and a sinewave as the grain wave. For this use, grain sizes of around 0.04 secs can be used. The formant centre frequency is determined by the grain pitch. Since this is a sampling increment, in order to use a frequency in Hz, that value has to be scaled by tablesiz/sr. Grain frequency will determine the fundamental.

This opcode is a variation on the *syncgrain* opcode.

### Note

diskgrain does not do any resampling, so if the sample rate of the source filename is not the same as csound's sr value there will be pitch shifts

## Examples

Here is an example of the diskgrain opcode. It uses the file *diskgrain.csd* [examples/diskgrain.csd].

# diskin

diskin — Reads audio data from an external device or stream and can alter its pitch.

## Description

Reads audio data from an external device or stream and can alter its pitch.

## Syntax

```
ar1 [, ar2 [, ar3 [, ... arN]]] diskin ifilcod[, kpitch[, iskptim \
[, iwraparound[, iformat[, iskipinit]]]]]
```

Note the N was 24 in versions before 5.14, and 40 after.

```
ar1[] diskin ifilcod[, kpitch[, iskptim \
[, iwraparound[, iformat[, iskipinit]]]]]
```

(in this version, the number of output channels is not limited.)

## Initialization

*ofilcod* -- integer or character-string denoting the source soundfile name. An integer denotes the file soundin.filcod ; a character-string (in double quotes, spaces permitted) gives the filename itself, optionally a full pathname. If not a full path, the named file is sought first in the current directory, then in that given by the environment variable *SSDIR* (if defined) then by *SFDIR*. See also *GEN01*.

*iskptim* (optional) -- time in seconds of input sound to be skipped. The default value is 0.

*iformat* (optional) -- specifies the audio data file format:

- 1 = 8-bit signed char (high-order 8 bits of a 16-bit integer)
- 2 = 8-bit A-law bytes
- 3 = 8-bit U-law bytes
- 4 = 16-bit short integers
- 5 = 32-bit long integers
- 6 = 32-bit floats
- 7 = 8-bit unsigned int (not available in Csound versions older than 5.00)
- 8 = 24-bit int (not available in Csound versions older than 5.00)
- 9 = 64-bit doubles (not available in Csound versions older than 5.00)

*iwraparound* -- 1 = on, 0 = off (wraps around to end of file either direction, enabling looping)

*iskipinit* switches off all initialisation if non zero (default =0). This was introduced in 4\_23f13 and csound5.

If *iformat* = 0 it is taken from the soundfile header, and if no header from the Csound -o command-line flag. The default value is 0.

## Performance

*a1 ... a24* -- output signals, in the range -0dbfs to 0dbfs. Any samples before the beginning (i.e. negative location) and after the end of the file are assumed to be zero, unless *iwrap* is non-zero. The number of output arguments must be the same as the number of sound file channels - which can be determined with the *filenchnl*s opcode, otherwise an init error will occur.

*ar1[]* --- output signals, in a-rate array of size N, where N is the number of channels in the file. Arrays are automatically allocated to the correct size.

*kpitch* -- can be any real number. A negative number signifies backwards playback. The given number is a pitch ratio, where:

- *I* = normal pitch (default)
- *2* = 1 octave higher
- *3* = 12th higher, etc.
- *.5* = 1 octave lower
- *.25* = 2 octaves lower, etc.
- *-I* = normal pitch backwards
- *-2* = 1 octave higher backwards, etc.

### Note to Windows users

Windows users typically use back-slashes, “\”, when specifying the paths of their files. As an example, a Windows user might use the path “c:\music\samples\loop001.wav”. This is problematic because back-slashes are normally used to specify special characters.

To correctly specify this path in Csound, one may alternately:

- Use forward slashes: c:/music/samples/loop001.wav
- Use back-slash special characters, “\\”: c:\\music\\samples\\loop001.wav

## Examples

Here is an example of the diskin opcode. It uses the file *diskin.csd* [examples/diskin.csd], *beats.wav* [examples/beats.wav].

### Example 195. Example of the diskin opcode.

# diskin2

diskin2 — Reads audio data from a file, and can alter its pitch using one of several available interpolation types, as well as convert the sample rate to match the orchestra sr setting.

## Description

Reads audio data from a file, and can alter its pitch using one of several available interpolation types, as well as convert the sample rate to match the orchestra sr setting. *diskin2* can also read multichannel files with any number of channels in the range 1 to 24 in versions before 5.14, and 40 after.

## Syntax

```
a1[, a2[, ... aN]] diskin2 ifilcod[, kpitch[, iskiptim \
[, iwrap[, iformat[, iwsize[, ibufsize[, iskipinit]]]]]]]
```

```
ar1[] diskin2 ifilcod[, kpitch[, iskiptim \
[, iwrap[, iformat[, iwsize[, ibufsize[, iskipinit]]]]]]]
```

(in the array output version, the number of output channels does not have an upper limit.)

## Initialization

*ifilcod* -- integer or character-string denoting the source soundfile name. An integer denotes the file soundin.ifilcod; a character-string (in double quotes, spaces permitted) gives the filename itself, optionally a full pathname. If not a full path, the named file is sought first in the current directory, then in those given by the environment variable *SSDIR* (if defined) then by *SFDIR*. See also *GEN01*. Note: files longer than  $2^{31}-1$  sample frames may not be played correctly on 32-bit platforms; this means a maximum length about 3 hours with a sample rate of 192000 Hz.

*iskiptim* (optional, defaults to zero) -- time in seconds of input sound to be skipped, assuming *kpitch*=1. Can be negative, to add *-iskiptim/kpitch* seconds of delay instead of skipping sound.

### Note

If *iwrap* is not 0 (locations are wrapped), *iskiptim* will not delay the sound if a negative value is used. Instead, the negative value will be "wrapped" from the end of the file.

*iwrap* (optional, defaults to zero) -- if set to any non-zero value, read locations that are negative or are beyond the end of the file are wrapped to the duration of the sound file instead of assuming zero samples. Useful for playing a file in a loop.

### Note

If *iwrap* is enabled, the file length should not be shorter than the interpolation window size (see below), otherwise there may be clicks in the sound output.

*iformat* (optional, defaults to zero) -- sample format, for raw (headerless) files only. This parameter is ignored if the file has a header. Allowed values are:

- 0: 16-bit short integers

- 1: 8-bit signed char (high-order 8 bits of a 16-bit integer)
- 2: 8-bit A-law bytes
- 3: 8-bit U-law bytes
- 4: 16-bit short integers
- 5: 32-bit long integers
- 6: 32-bit floats
- 7: 8-bit unsigned int
- 8: 24-bit int
- 9: 64-bit doubles

*iwsize* (optional, defaults to zero) -- interpolation window size, in samples. Can be one of the following:

- 1: round to nearest sample (no interpolation, for *kpitch*=1)
- 2: linear interpolation
- 4: cubic interpolation
- $\geq 8$ : *iwsize* point sinc interpolation with anti-aliasing (slow)

Zero or negative values select the default, which is cubic interpolation.

### Note

If interpolation is used, *kpitch* is automatically scaled by the ratio of the sample rate of the sound file and the orchestra, so that the file will always be played at the original pitch if *kpitch* is 1. However, the sample rate conversion is disabled if *iwsize* is 1.

*ibufsize* (optional, defaults to 0) -- buffer size in mono samples (not sample frames). This is only the suggested value, the actual setting will be rounded so that the number of sample frames is an integer power of two and is in the range 128 (or *iwsize* if greater than 128) to 1048576. The default, which is 4096, and is enabled by zero or negative values, should be suitable for most uses, but for non-realtime mixing of many large sound files, a high buffer setting is recommended to improve the efficiency of disk reads. For real time audio output, reading the files from a fast RAM file system (on platforms where this option is available) with a small buffer size may be preferred.

*iskipinit* (optional, defaults to 0) -- skip initialization if set to any non-zero value.

## Performance

*a1 ... a24* -- output signals, in the range -0dbfs to 0dbfs. Any samples before the beginning (i.e. negative location) and after the end of the file are assumed to be zero, unless *iwrap* is non-zero. The number of output arguments must be the same as the number of sound file channels - which can be determined with the *filenchnl* opcode, otherwise an init error will occur.

*ar1[]* --- output signals, in a-rate array of size N, where N is the number of channels in the file. Arrays are automatically allocated to the correct size.

## Note

It is more efficient to read a single file with many channels, than many files with only a single channel, especially with high *iwsiz*e settings.

*kpitch* -- transpose the pitch of input sound by this factor (e.g. 0.5 means one octave lower, 2 is one octave higher, and 1 is the original pitch, which is the default value). Fractional and negative values are allowed (the latter results in playing the file backwards, however, in this case the skip time parameter should be set to some positive value, e.g. the length of the file, or *iwrap* should be non-zero, otherwise nothing would be played). If interpolation is enabled, and the sample rate of the file differs from the orchestra sample rate, the transpose ratio is automatically adjusted to make sure that *kpitch*=1 plays at the original pitch. Using a high *iwsiz*e setting (40 or more) can significantly improve sound quality when transposing up, although at the expense of high CPU usage.

## Examples

Here is an example of the *diskin2* opcode. It uses the file *diskin2.csd* [examples/diskin2.csd], *beats.wav* [examples/beats.wav].

### Example 196. Example of the *diskin2* opcode.

# dispfft

`displayfft` — Displays the Fourier Transform of an audio or control signal.

## Description

These units will print orchestra init-values, or produce graphic display of orchestra control signals and audio signals. Uses X11 windows if enabled, else (or if -g flag is set) displays are approximated in ASCII characters.

## Syntax

```
dispfft xsig, iprd, iwsiz [, iwttyp] [, idbout] [, iwtflg] [,imin] [,imax]
```

## Initialization

*iprd* -- the period of display in seconds.

*iwsiz* -- size of the input window in samples. A window of *iwsiz* points will produce a Fourier transform of *iwsiz*/2 points, spread linearly in frequency from 0 to sr/2. *iwsiz* must be a power of 2, with a minimum of 16 and a maximum of 4096. The windows are permitted to overlap.

*iwttyp* (optional, default=0) -- window type. 0 = rectangular, 1 = Hanning. The default value is 0 (rectangular).

*idbout* (optional, default=0) -- units of output for the Fourier coefficients. 0 = magnitude, 1 = decibels. The default is 0 (magnitude).

*iwtflg* (optional, default=0) -- wait flag. If non-zero, each display is held until released by the user. The default value is 0 (no wait).

*imin* (optional, default=0) -- minimum FFT bin used in display.

*imax* (optional, default=winsize/2) -- maximum FFT bin to be used in display.

## Performance

`dispfft` -- displays the Fourier Transform of an audio or control signal (*asig* or *ksig*) every *iprd* seconds using the Fast Fourier Transform method.

## Examples

Here is an example of the `dispfft` opcode. It uses the file `dispfft.csd` [examples/dispfft.csd].

### Example 197. Example of the `dispfft` opcode.

*display, print*

# display

`display` — Displays the audio or control signals as an amplitude vs. time graph.

## Description

These units will print orchestra init-values, or produce graphic display of orchestra control signals and audio signals. Uses X11 windows if enabled, else (or if -g flag is set) displays are approximated in ASCII characters.

## Syntax

```
display xsig, iprd [, inprds] [, iwtflg]
```

## Initialization

*iprd* -- the period of display in seconds.

*inprds* (optional, default=1) -- Number of display periods retained in each display graph. A value of 2 or more will provide a larger perspective of the signal motion. The default value is 1 (each graph completely new). *inprds* is a scaling factor for the displayed waveform, controlling how many *iprd*-sized frames of samples are drawn in the window (the default and minimum value is 1.0). Higher *inprds* values are slower to draw (more points to draw) but will show the waveform scrolling through the window, which is useful with low *iprd* values.

*iwtflg* (optional, default=0) -- wait flag. If non-zero, each display is held until released by the user. The default value is 0 (no wait).

## Performance

`display` -- displays the audio or control signal *xsig* every *iprd* seconds, as an amplitude vs. time graph.

## Examples

Here is an example of the `display` opcode. It uses the file `display.csd` [examples/display.csd].

# distort

*distort* — Distort an audio signal via waveshaping and optional clipping.

## Description

Distort an audio signal via waveshaping and optional clipping.

## Syntax

```
ar distort asig, kdist, ifn[, ihp, istor]
```

## Initialization

*ifn* -- table number of a waveshaping function with extended guard point. The function can be of any shape, but it should pass through 0 with positive slope at the table mid-point. The table size need not be large, since it is read with interpolation.

*ihp* -- (optional) half-power point (in cps) of an internal low-pass filter. The default value is 10.

*istor* -- (optional) initial disposition of internal data space (see reson). The default value is 0.

## Performance

*asig* -- Audio signal to be processed

*kdist* -- Amount of distortion (usually between 0 and 1)

This unit distorts an incoming signal using a waveshaping function *ifn* and a distortion index *kdist*. The input signal is first compressed using a running rms, then passed through a waveshaping function which may modify its shape and spectrum. Finally it is rescaled to approximately its original power.

The amount of distortion depends on the nature of the shaping function and on the value of *kdist*, which generally ranges from 0 to 1. For low values of *kdist*, we should like the shaping function to pass the signal almost unchanged. This will be the case if, at the mid-point of the table, the shaping function is near-linear and is passing through 0 with positive slope. A line function from -1 to +1 will satisfy this requirement; so too will a sigmoid (sinusoid from 270 to 90 degrees). As *kdist* is increased, the compressed signal is expanded to encounter more and more of the shaping function, and if this becomes non-linear the signal is increasingly *bent* on read-through to cause distortion.

When *kdist* becomes large enough, the read-through process will eventually hit the outer limits of the table. The table is not read with wrap-around, but will “stick” at the end-points as the incoming signal exceeds them; this introduces clipping, an additional form of signal distortion. The point at which clipping begins will depend on the complexity (rms-to-peak value) of the input signal. For a pure sinusoid, clipping will begin only as *kdist* exceeds 0.7; for a more complex input, clipping might begin at a *kdist* of 0.5 or much less. *kdist* can exceed the clip point by any amount, and may be greater than 1.

The shaping function can be made arbitrarily complex for extra effect. It should generally be continuous, though this is not a requirement. It should also be well-behaved near the mid-point, and roughly balanced positive-negative overall, else some excessive DC offset may result. The user might experiment with more aggressive functions to suit the purpose. A generally positive slope allows the distorted signal to be mixed with the source without phase cancellation.

*distort* is useful as an effects process, and is usually combined with reverb and chorusing on effects busses. However, it can alternatively be used to good effect within a single instrument.

## Examples

Here is an example of the distort opcode. It uses the file *distort.csd* [examples/distort.csd].

### Example 199. Example of the distort opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# distort1

distort1 — Modified hyperbolic tangent distortion.

## Description

Implementation of modified hyperbolic tangent distortion. *distort1* can be used to generate wave shaping distortion based on a modification of the *tanh* function.

$$aout = \frac{\exp(asig * (shape1 + pregain)) - \exp(asig * (shape2 - pregain))}{\exp(asig * pregain) + \exp(-asig * pregain)}$$

## Syntax

```
ares distort1 asig, kpregain, kpostgain, kshape1, kshape2[, imode]
```

## Initialization

*imode* (Csound version 5.00 and later only; optional, defaults to 0) -- scales kpregain, kpostgain, kshape1, and kshape2 for use with audio signals in the range -32768 to 32768 (*imode*=0), -0dbfs to 0dbfs (*imode*=1), or disables scaling of kpregain and kpostgain and scales kshape1 by kpregain and kshape2 by -kpregain (*imode*=2).

## Performance

*asig* -- is the input signal.

*kpregain* -- determines the amount of gain applied to the signal before waveshaping. A value of 1 gives slight distortion.

*kpostgain* -- determines the amount of gain applied to the signal after waveshaping.

*kshape1* -- determines the shape of the positive part of the curve. A value of 0 gives a flat clip, small positive values give sloped shaping.

*kshape2* -- determines the shape of the negative part of the curve.

## Examples

Here is an example of the distort1 opcode. It uses the file *distort1.csd* [examples/distort1.csd].

### Example 200. Example of the distort1 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# divz

divz — Safely divides two numbers.

## Syntax

```
ares divz xa, xb, ksubst  
  
ires divz ia, ib, isubst  
  
kres divz ka, kb, ksubst  
  
. . . divz(ka, kb, ksubst) . . . (no rate restriction)
```

## Description

Safely divides two numbers.

## Initialization

Whenever  $b$  is not zero, set the result to the value  $a / b$ ; when  $b$  is zero, set it to the value of *subst* instead.

## Examples

Here is an example of the divz opcode. It uses the file *divz.csd* [examples/divz.csd].

### Example 201. Example of the divz opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# doppler

**doppler** — A fast and robust method for approximating sound propagation, achieving convincing Doppler shifts without having to solve equations.

## Description

A fast and robust method for approximating sound propagation, achieving convincing Doppler shifts without having to solve equations. The method computes frequency shifts based on reading an input delay line at a delay time computed from the distance between source and mic and the speed of sound. One instance of the opcode is required for each dimension of space through which the sound source moves. If the source sound moves at a constant speed from in front of the microphone, through the microphone, to behind the microphone, then the output will be frequency shifted above the source frequency at a constant frequency while the source approaches, then discontinuously will be shifted below the source frequency at a constant frequency as the source recedes from the microphone. If the source sound moves at a constant speed through a point to one side of the microphone, then the rate of change of position will not be constant, and the familiar Doppler frequency shift typical of a siren or engine approaching and receding along a road beside a listener will be heard.

## Syntax

```
ashifted doppler asource, ksourceposition, kmicposition [, isoundspeed, ifiltercutoff]
```

## Initialization

*isoundspeed* (optional, default=340.29) -- Speed of sound in meters/second.

*ifiltercutoff* (optional, default=6) -- Rate of updating the position smoothing filter, in cycles/second.

## Performance

*asource* -- Input signal at the sound source.

*ksourceposition* -- Position of the source sound in meters. The distance between source and mic should not be changed faster than about 3/4 the speed of sound.

*kmicposition* -- Position of the recording microphone in meters. The distance between source and mic should not be changed faster than about 3/4 the speed of sound.

## Examples

Here is an example of the doppler opcode. It uses the file *doppler.csd* [examples/doppler.csd].

### Example 202. Example of the doppler opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# downsamp

downsamp — Modify a signal by down-sampling.

## Description

Modify a signal by down-sampling.

## Syntax

```
kres downsamp asig [, iwlen]
```

## Initialization

*iwlen* (optional) -- window length in samples over which the audio signal is averaged to determine a downsampled value. Maximum length is *ksmps*; 0 and 1 imply no window averaging. The default value is 0.

## Performance

*downsamp* converts an audio signal to a control signal by downsampling. It produces one kval for each audio control period. The optional window invokes a simple averaging process to suppress foldover.

## Examples

Here is an example of the *downsamp* opcode. It uses the file *downsamp.csd* [examples/downsamp.csd].

### Example 203. Example of the *downsamp* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# dripwater

dripwater — Semi-physical model of a water drop.

## Description

*dripwater* is a semi-physical model of a water drop. It is one of the PhISEM percussion opcodes. PhISEM (Physically Informed Stochastic Event Modeling) is an algorithmic approach for simulating collisions of multiple independent sound producing objects.

## Syntax

```
ares dripwater kamp, idettack [, inum] [, idamp] [, imaxshake] [, ifreq] \
[, ifreq1] [, ifreq2]
```

## Initialization

*idettack* -- period of time over which all sound is stopped

*inum* (optional) -- The number of beads, teeth, bells, timbrels, etc. If zero, the default value is 10.

*idamp* (optional) -- the damping factor, as part of this equation:

$$\text{damping\_amount} = 0.996 + (\text{idamp} * 0.002)$$

The default *damping\_amount* is 0.996 which means that the default value of *idamp* is 0. The maximum *damping\_amount* is 1.0 (no damping). This means the maximum value for *idamp* is 2.0.

The recommended range for *idamp* is usually below 75% of the maximum value. Rasmus Ekman suggests a range of 1.4-1.75. He also suggests a maximum value of 1.9 instead of the theoretical limit of 2.0.

*imaxshake* (optional, default=0) -- amount of energy to add back into the system. The value should be in range 0 to 1.

*ifreq* (optional) -- the main resonant frequency. The default value is 450.

*ifreq1* (optional) -- the first resonant frequency. The default value is 600.

*ifreq2* (optional) -- the second resonant frequency. The default value is 750.

## Performance

*kamp* -- Amplitude of output. Note: As these instruments are stochastic, this is only an approximation.

## Examples

Here is an example of the dripwater opcode. It uses the file *dripwater.csd* [examples/dripwater.csd].

### Example 204. Example of the dripwater opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# dssiactivate

dssiactivate — Activates or deactivates a DSSI or LADSPA plugin.

## Note

plugin: Requires dssi4cs plugin

## Syntax

```
dssiactivate ihandle, ktoggle
```

## Description

*dssiactivate* is used to activate or deactivate a DSSI or LADSPA plugin. It calls the plugin's activate() and deactivate() functions if they are provided.

## Initialization

*ihandle* - the number which identifies the plugin, generated by *dssiinit*.

## Performance

*ktoggle* - Selects between activation (*ktoggle*=1) and deactivation (*ktoggle*=0).

*dssiactivate* is used to turn on and off plugins if they provide this facility. This may help conserve CPU processing in some cases. For consistency, all plugins must be activated to produce sound. An inactive plugin produces silence.

Depending on the plugin's implementation, this may cause interruptions in the realtime audio process, so use with caution.

*dssiactivate* may cause audio stream breakups when used in realtime, so it is recommended to load all plugins to be used before playing.

## Warning

Please note that even if activate() and deactivate() functions are not present in a plugin, *dssiactivate* must be called for the plugin to produce sound.

## Examples

Here is an example of the dssiactivate opcode. It uses the file *dssiactivate.csd* [examples/dssiactivate.csd].

### Example 205. Example of the dssiactivate opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# dssiaudio

dssiaudio — Processes audio using a LADSPA or DSSI plugin.

## Note

plugin: Requires dssi4cs plugin

## Syntax

```
[aout1, aout2, ..., aout9] dssiaudio ihandle, [ain1, ain2, ..., ain9]
```

## Description

*dssiaudio* generates audio by processing an input signal through a LADSPA plugin.

## Initialization

*ihandle* - handle for the plugin returned by *dssiinit*

## Performance

*aout1, aout2, etc* - Audio output generated by the plugin

*ain1, ain2, etc* - Audio provided to the plugin for processing

*dssiaudio* runs a plugin on the provided audio and produces audio output. Currently up to four inputs and outputs are provided. You should provide signal for all the plugins audio inputs, otherwise unpredictable results may occur. If the plugin doesn't have any input (e.g Noise generator) you must still provide at least one input variable, which will be ignored with a message.

Only one *dssiaudio* should be executed once per plugin, or strange results may occur.

## Examples

Here is an example of the dssiaudio opcode. It uses the file *dssiaudio.csd* [examples/dssiaudio.csd].

### Example 206. Example of the dssiaudio opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# dssictls

dssictls — Send control information to a LADSPA or DSSI plugin.

## Note

plugin: Requires dssi4cs plugin

## Syntax

```
dssictls ihandle, iport, kvalue, ktrigger
```

## Description

*dssictls* sends control values to a plugin's control port

## Initialization

*ihandle* - handle for the plugin returned by *dssiinit*

*iport* - control port number

## Performance

*kvalue* - value to be assigned to the port

*ktrigger* - determines whether the control information will be sent (*ktrigger* = 1) or not. This is useful for thinning control information, generating *ktrigger* with *metro*

*dssictls* sends control information to a LADSPA or DSSI plugin's control port. The valid control ports and ranges are given by *dssiinit*. Using values outside the ranges may produce unspecified behaviour.

## Examples

Here is an example of the dssictls opcode. It uses the file *dssictls.csd* [examples/dssictls.csd].

### Example 207. Example of the dssictls opcode.

# dssiinit

dssiinit — Loads a DSSI or LADSPA plugin.

## Note

plugin: Requires dssi4cs plugin

## Syntax

```
ihandle dssiinit ilibraryname, iplugindex [, iverbose]
```

## Description

*dssiinit* is used to load a DSSI or LADSPA plugin into memory for use with the other dssi4cs opcodes. Both LADSPA effects and DSSI instruments can be used.

## Initialization

*ihandle* - the number which identifies the plugin, to be passed to other dssi4cs opcodes.

*ilibraryname* - the name of the .so (shared object) file to load.

*iplugindex* - The index of the plugin to be used.

*iverbose* (optional) - show plugin information and parameters when loading. (default = 1)

*dssiinit* looks for *ilibraryname* on LADSPA\_PATH and DSSI\_PATH. One of these variables must be set, otherwise *dssiinit* will return an error. LADSPA and DSSI libraries may contain more than one plugin which must be referenced by its index. *dssiinit* then attempts to find plugin index *iplugindex* in the library and load the plugin into memory if it is found. To find out which plugins you have available and their index numbers you can use: *dssilist*.

If *iverbose* is not 0 (the default), information about the plugin detailing its characteristics and its ports will be shown. This information is important for opcodes like *dssicils*.

Plugins are set to inactive by default, so you *\*must\** use *dssiactivate* to get the plugin to produce sound. This is required even if the plugin doesn't provide an activate() function.

*dssiinit* may cause audio stream breakups when used in realtime, so it is recommended to load all plugins to be used before playing.

## Examples

Here is an example of the dssiinit opcode. It uses the file *dssiinit.csd* [examples/dssiinit.csd].

### Example 208. Example of the dssiinit opcode. (Remember to change the Library name)

```

# dssilist

dssilist — Lists all available DSSI and LADSPA plugins.

## Note

plugin: Requires dssi4cs plugin

## Syntax

`dssilist`

## Description

*dssilist* checks the variables DSSI\_PATH and LADSPA\_PATH and lists all plugins available in all plugin libraries there.

LADSPA and DSSI libraries may contain more than one plugin which must be referenced by the index provided by *dssilist*.

This opcode produces a long printout which may interrupt realtime audio output, so it should be run at the start of a performance.

## Examples

Here is an example of the dssilist opcode. It uses the file *dssilist.csd* [examples/dssilist.csd].

### Example 209. Example of the dssilist opcode. (Remember to change the Library name)

# dumpk

dumpk — Periodically writes an orchestra control-signal value to an external file.

## Description

Periodically writes an orchestra control-signal value to a named external file in a specific format.

## Syntax

```
dumpk  ksig, ifilename, iformat, iprd
```

## Initialization

*filename* -- character string (in double quotes, spaces permitted) denoting the external file name. May either be a full path name with target directory specified or a simple filename to be created within the current directory

*iformat* -- specifies the output data format:

- 1 = 8-bit signed char(high order 8 bits of a 16-bit integer)
- 4 = 16-bit short integers
- 5 = 32-bit long integers
- 6 = 32-bit floats
- 7 = ASCII long integers
- 8 = ASCII floats (2 decimal places)

Note that A-law and U-law output are not available, and that all formats except the last two are binary. The output file contains no header information.

*iprd* -- the period of *ksig* output in seconds, rounded to the nearest orchestra control period. A value of 0 implies one control period (the enforced minimum), which will create an output file sampled at the orchestra control rate.

## Performance

*ksig* -- a control-rate signal

This opcode allows a generated control signal value to be saved in a named external file. The file contains no self-defining header information. But it contains a regularly sampled time series, suitable for later input or analysis. There may be any number of *dumpk* opcodes in an instrument or orchestra but each must write to a different file.

## Examples

Here is an example of the *dumpk* opcode. It uses the file *dumpk.csd* [examples/dumpk.csd].

**Example 210. Example of the dumpk opcode.**

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# dumpk2

dumpk2 — Periodically writes two orchestra control-signal values to an external file.

## Description

Periodically writes two orchestra control-signal values to a named external file in a specific format.

## Syntax

```
dumpk2 ksig1, ksig2, ifilename, iformat, iprd
```

## Initialization

*filename* -- character string (in double quotes, spaces permitted) denoting the external file name. May either be a full path name with target directory specified or a simple filename to be created within the current directory

*iformat* -- specifies the output data format:

- 1 = 8-bit signed char(high order 8 bits of a 16-bit integer)
- 4 = 16-bit short integers
- 5 = 32-bit long integers
- 6 = 32-bit floats
- 7 = ASCII long integers
- 8 = ASCII floats (2 decimal places)

Note that A-law and U-law output are not available, and that all formats except the last two are binary. The output file contains no header information.

*iprd* -- the period of *ksig* output in seconds, rounded to the nearest orchestra control period. A value of 0 implies one control period (the enforced minimum), which will create an output file sampled at the orchestra control rate.

## Performance

*ksig1, ksig2* -- control-rate signals.

This opcode allows two generated control signal values to be saved in a named external file. The file contains no self-defining header information. But it contains a regularly sampled time series, suitable for later input or analysis. There may be any number of *dumpk2* opcodes in an instrument or orchestra but each must write to a different file.

## Examples

# duserrnd

duserrnd — Discrete USER-defined-distribution RaNDom generator.

## Description

Discrete USER-defined-distribution RaNDom generator.

## Syntax

```
aout duserrnd ktableNum  
  
iout duserrnd itableNum  
  
kout duserrnd ktableNum
```

## Initialization

*itableNum* -- number of table containing the random-distribution function. Such table is generated by the user. See GEN40, GEN41, and GEN42. The table length does not need to be a power of 2

## Performance

*ktableNum* -- number of table containing the random-distribution function. Such table is generated by the user. See GEN40, GEN41, and GEN42. The table length does not need to be a power of 2

*duserrnd* (discrete user-defined-distribution random generator) generates random values according to a discrete random distribution created by the user. The user can create the discrete distribution histogram by using GEN41. In order to create that table, the user has to define an arbitrary amount of number pairs, the first number of each pair representing a value and the second representing its probability (see GEN41 for more details).

When used as a function, the rate of generation depends by the rate type of input variable XtableNum. In this case it can be embedded into any formula. Table number can be varied at k-rate, allowing to change the distribution histogram during the performance of a single note. *duserrnd* is designed be used in algorithmic music generation.

*duserrnd* can also be used to generate values following a set of ranges of probabilities by using distribution functions generated by GEN42 (See GEN42 for more details). In this case, in order to simulate continuous ranges, the length of table XtableNum should be reasonably big, as *duserrnd* does not interpolate between table elements.

For a tutorial about random distribution histograms and functions see:

- D. Lorrain. "A panoply of stochastic cannons". In C. Roads, ed. 1989. Music machine. Cambridge, Massachusetts: MIT press, pp. 351 - 379.

## Examples

Here is an example of the duserrnd opcode. It uses the file *duserrnd.csd* [examples/duserrnd.csd].

**Example 215. Example of the duserrnd opcode.**

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## else

`else` — Executes a block of code when an "if...then" condition is false.

## Description

Executes a block of code when an "if...then" condition is false.

## Syntax

```
else
```

## Performance

`else` is used inside of a block of code between the "*if...then*" and *endif* opcodes. It defines which statements are executed when a "if...then" condition is false. Only one `else` statement may occur and it must be the last conditional statement before the *endif* opcode.

## Examples

Here is an example of the `else` opcode. It uses the file `else.csd` [examples/else.csd].

### Example 218. Example of the else opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>

# elseif

elseif — Defines another "if...then" condition when a "if...then" condition is false.

## Description

Defines another "if...then" condition when a "if...then" condition is false.

## Syntax

```
elseif xa R xb then
```

where *label* is in the same instrument block and is not an expression, and where *R* is one of the Relational operators (*<*, *=*, *<=*, *==*, *!=*) (and *=* for convenience, see also under *Conditional Values*).

## Performance

*elseif* is used inside of a block of code between the "*if...then*" and *endif* opcodes. When a "if...then" condition is false, it defines another "if...then" condition to be met. Any number of *elseif* statements are allowed.

## Examples

Here is an example of the *elseif* opcode. It uses the file *elseif.csd* [examples/elseif.csd].

### Example 219. Example of the elseif opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## endif

endif — Closes a block of code that begins with an "if...then" statement.

## Description

Closes a block of code that begins with an "*if...then*" statement.

## Syntax

```
endif
```

## Performance

Any block of code that begins with an "*if...then*" statement must end with an *endif* statement.

## Examples

Here is an example of the *endif* opcode. It uses the file *endif.csd* [examples/endif.csd].

### Example 220. Example of the endif opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# endin

endin — Ends the current instrument block.

## Description

Ends the current instrument block.

## Syntax

```
endin
```

## Initialization

Ends the current instrument block.

Instruments can be defined in any order (but they will always be both initialized and performed in ascending instrument number order). Instrument blocks cannot be nested (i.e. one block cannot contain another).

### Note

There may be any number of instrument blocks in an orchestra.

## Examples

Here is an example of the endin opcode. It uses the file *endin.csd* [examples/endin.csd].

### Example 221. Example of the endin opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# endop

endop — Marks the end of an user-defined opcode block.

## Description

Marks the end of an user-defined opcode block.

## Syntax

```
endop
```

## Performance

The syntax of a user-defined opcode block is as follows:

```
opcode  name, outtypes, intypes
xinarg1 [, xinarg2] [, xinarg3] ... [xinargN]  xin
[setksmps  iksmps]
... the rest of the instrument's code.
xout  xoutarg1 [, xoutarg2] [, xoutarg3] ... [xoutargN]
endop
```

The new opcode can then be used with the usual syntax:

```
[xinarg1] [, xinarg2] ... [xinargN]  name  [xoutarg1] [, xoutarg2] ... [xoutargN] [, iksmps]
```

## Examples

Here is an example of the endop opcode. It uses the file *endop.csd* [examples/endop.csd].

### Example 222. Example of the endop opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# envlp

`envlp` — Applies an envelope consisting of 3 segments.

## Description

*envlp* -- apply an envelope consisting of 3 segments:

1. stored function rise shape
2. modified exponential pseudo steady state
3. exponential decay

## Syntax

```
ares envlp xamp, irise, idur, idec, ifn, iatss, iatdec [, ixmod]
```

```
kres envlp kamp, irise, idur, idec, ifn, iatss, iatdec [, ixmod]
```

## Initialization

*irise* -- rise time in seconds. A zero or negative value signifies no rise modification.

*idur* -- overall duration in seconds. A zero or negative value will cause initialization to be skipped.

*idec* -- decay time in seconds. Zero means no decay. An *idec* > *idur* will cause a truncated decay.

*ifn* -- function table number of stored rise shape with extended guard point.

*iatss* -- attenuation factor, by which the last value of the *envlp* rise is modified during the note's pseudo steady state. A factor greater than 1 causes an exponential growth and a factor less than 1 creates an exponential decay. A factor of 1 will maintain a true steady state at the last rise value. Note that this attenuation is not by fixed rate (as in a piano), but is sensitive to a note's duration. However, if *iatss* is negative (or if steady state < 4 k-periods) a fixed attenuation rate of *abs(iatss)* per second will be used. 0 is illegal.

*iatdec* -- attenuation factor by which the closing steady state value is reduced exponentially over the decay period. This value must be positive and is normally of the order of .01. A large or excessively small value is apt to produce a cutoff which is audible. A zero or negative value is illegal.

*ixmod* (optional, between +- .9 or so) -- exponential curve modifier, influencing the steepness of the exponential trajectory during the steady state. Values less than zero will cause an accelerated growth or decay towards the target (e.g. *subito piano*). Values greater than zero will cause a retarded growth or decay. The default value is zero (unmodified exponential).

## Performance

*kamp*, *xamp* -- input amplitude signal.

Rise modifications are applied for the first *irise* seconds, and decay from time *idur* - *idec*. If these peri-

ods are separated in time there will be a steady state during which *amp* will be modified by the first exponential pattern. If rise and decay periods overlap then both modifications will be in effect for that time. If the overall duration *idur* is exceeded in performance, the final decay will continue on in the same direction, tending asymptotically to zero.

## Examples

Here is an example of the *envlpx* opcode. It uses the file *envlpx.csd* [examples/envlpx.csd].

### Example 223. Example of the *envlpx* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# envelope extender

`envelope extender` — The `envlpx` opcode with a final release segment.

## Description

`envelope extender` is the same as `envlpx` except that the final segment is entered only on sensing a MIDI note release. The note is then extended by the decay time.

## Syntax

```
ares envelope extender xamp, irise, idec, ifn, iatss, iatdec [, ixmod] [,irind]
```

```
kres envelope extender kamp, irise, idec, ifn, iatss, iatdec [, ixmod] [,irind]
```

## Initialization

*irise* -- rise time in seconds. A zero or negative value signifies no rise modification.

*idec* -- decay time in seconds. Zero means no decay.

*ifn* -- function table number of stored rise shape with extended guard point.

*iatss* -- attenuation factor, by which the last value of the `envelope extender` rise is modified during the note's pseudo steady state. A factor greater than 1 causes an exponential growth and a factor less than 1 creates an exponential decay. A factor of 1 will maintain a true steady state at the last rise value. Note that this attenuation is not by fixed rate (as in a piano), but is sensitive to a note's duration. However, if *iatss* is negative (or if steady state < 4 k-periods) a fixed attenuation rate of *abs(iatss)* per second will be used. 0 is illegal.

*iatdec* -- attenuation factor by which the closing steady state value is reduced exponentially over the decay period. This value must be positive and is normally of the order of .01. A large or excessively small value is apt to produce a cutoff which is audible. A zero or negative value is illegal.

*ixmod* (optional, between +- .9 or so) -- exponential curve modifier, influencing the steepness of the exponential trajectory during the steady state. Values less than zero will cause an accelerated growth or decay towards the target (e.g. *subito piano*). Values greater than zero will cause a retarded growth or decay. The default value is zero (unmodified exponential).

*irind* (optional) -- independence flag. If left zero, the release time (*idec*) will influence the extended life of the current note following a note-off. If non-zero, the *idec* time is quite independent of the note extension (see below). The default value is 0.

## Performance

*kamp*, *xamp* -- input amplitude signal.

`envelope extender` is an example of the special Csound “r” units that contain a note-off sensor and release time extender. When each senses a score event termination or a MIDI noteoff, it will immediately extend the performance time of the current instrument by *idec* seconds unless it is made independent by *irind*. Then it will begin a decay from wherever it was at the time.

You can use other pre-made envelopes which start a release segment upon receiving a note off message,

like *linsegr* and *expsegr*, or you can construct more complex envelopes using *xtratim* and *release*. Note that you don't need to use *xtratim* if you are using *envlpxr*, since the time is extended automatically.

These “r” units can also be modified by MIDI noteoff velocities (see *veloffs*). If the *irind* flag is on (non-zero), the overall performance time is unaffected by note-off and veloff data.

**Multiple “r” units.** When two or more “r” units occur in the same instrument it is usual to have only one of them influence the overall note duration. This is normally the master amplitude unit. Other units controlling, say, filter motion can still be sensitive to note-off commands while not affecting the duration by making them independent (*irind* non-zero). Depending on their own *idec* (release time) values, independent “r” units may or may not reach their final destinations before the instrument terminates. If they do, they will simply hold their target values until termination. If two or more “r” units are simultaneously master, note extension is by the greatest *idec*.

## Examples

Here is an example of the *envlpxr* opcode. It uses the file *envlpxr.csd* [examples/envlpxr.csd].

### Example 224. Example of the *envlpxr* opcode.

# ephasor

ephasor — produces two outputs: a periodic phase signal and a periodic exponential decaying signal.

## Description

This opcode produces two outputs: a periodic phase signal (like the phasor opcode), and a periodic exponential decaying signal. The latter is synchronised to the former, starting at 1 and then decreasing at the same time as the phase signal increases from 0 to 1. The rate of exponential decay can be controlled by the second parameter.

## Syntax

```
aexp,aph ephasor kfreq, kR
```

## Performance

*kfreq* - the rate at which the phase and exponential signals are generated

*kR* - a parameter controlling the decay rate of the exponential signal,  $0 < kR < 1$ . Lower values produce faster decays.

## Examples

Here is an example of the ephasor opcode. It uses the file *ephasor.csd* [examples/ephasor.csd].

### Example 225. Example of the ephasor opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# eqfil

eqfil — Equalizer filter

## Description

The opcode eqfil is a 2nd order tunable equalisation filter based on Regalia and Mitra design ("Tunable Digital Frequency Response Equalization Filters", IEEE Trans. on Ac., Sp. and Sig Proc., 35 (1), 1987). It provides a peak/notch filter for building parametric/graphic equalisers.

The amplitude response for this filter will be flat (=1) for *kgain*=1. With *kgain* bigger than 1, there will be a peak at the centre frequency, whose width is given by the *kbw* parameter, but outside this band, the response will tend towards 1. Conversely, if *kgain* is smaller than 1, a notch will be created around the CF.

## Syntax

```
asig eqfil ain, kcf, kbw, kgain[, istor]
```

## Initialization

*istor* --initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*asig* -- filtered output signal.

*ain* -- input signal.

*kcf* -- filter centre frequency.

*kbw* -- peak/notch bandwidth (Hz).

*kgain* -- peak/notch gain.

## Examples

Here is an example of the eqfil opcode. It uses the file *eqfil.csd* [examples/eqfil.csd].

### Example 226. Example of the eqfil opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## evalstr

evalstr — Evalstrs evaluates a string containing Csound code, returning a value.

## Description

Evalstr compiles and runs Csound code and returns a value from the global space (instr 0). This opcode can be also used to compile new instruments (as compilestr).

## Syntax

```
iros evalstr Scode  
kres evalstr Scode, ktrig
```

## Initialization

“*Scode*” -- a string to be compiled and evaluated.

## Performance

“*ktrig*” -- triggers the compilation/evaluation if non-zero.

## Examples

Here is an example of the evalstr opcode in conjunction with return:

### Example 227.

```
ival evalstr "return 2 + 2"  
print ival
```

# event

`event` — Generates a score event from an instrument.

## Description

Generates a score event from an instrument.

## Syntax

```
event "scorechar",kinsnum,kdelay,kdur,[,kp4][,kp5][,...]  
event "scorechar","insname",kdelay,kdur,[,kp4][,kp5][,...]
```

## Initialization

`"scorechar"` -- A string (in double-quotes) representing the first p-field in a score statement. This is usually `"e"`, `"f"`, or `"i"`.

`"insname"` -- A string (in double-quotes) representing a named instrument.

## Performance

`kinsnum` -- The instrument to use for the event. This corresponds to the first p-field, p1, in a score statement.

`kdelay` -- When (in seconds) the event will occur from the current performance time. This corresponds to the second p-field, p2, in a score statement.

`kdur` -- How long (in seconds) the event will happen. This corresponds to the third p-field, p3, in a score statement.

`kp4, kp5, ...` (optional) -- Parameters representing additional p-field in a score statement. It starts with the fourth p-field, p4.

### Note

Note that the `event` opcode cannot accept string p-fields. If you need to pass strings when instantiating an instrument, use the `scoreline` or `scoreline_i` opcode.

## Examples

Here is an example of the `event` opcode. It uses the file `event.csd` [examples/event.csd].

### Example 228. Example of the event opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

Thanks goes to Matt Ingalls for helping clarify the kwhen/kdelay parameter.

## event\_i

event\_i — Generates a score event from an instrument.

## Description

Generates a score event from an instrument.

## Syntax

```
event_i "scorechar", iinsnum, idelay, idur, [, ip4] [, ip5] [, ...]  
event_i "scorechar", "insname", idelay, idur, [, ip4] [, ip5] [, ...]
```

## Initialization

“scorechar” -- A string (in double-quotes) representing the first p-field in a score statement. This is usually “e”, “f”, or “i”.

“insname” -- A string (in double-quotes) representing a named instrument.

*iinsnum* -- The instrument to use for the event. This corresponds to the first p-field, p1, in a score statement.

*idelay* -- When (in seconds) the event will occur from the current performance time. This corresponds to the second p-field, p2, in a score statement.

*idur* -- How long (in seconds) the event will happen. This corresponds to the third p-field, p3, in a score statement.

*ip4, ip5, ...* (optional) -- Parameters representing additional p-field in a score statement. It starts with the fourth p-field, p4.

## Performance

The event is added to the queue at initialisation time.

### Note

Note that the *event\_i* opcode cannot accept string p-fields. If you need to pass strings when instantiating an instrument, use the *scoreline* or *scoreline\_i* opcode.

## Examples

Here is an example of the *event\_i* opcode. It uses the file *event\_i.csd* [examples/event\_i.csd].

### Example 230. Example of the event\_i opcode.

# exciter

`exciter` — A non-linear filter system to excite the signal.

## Description

"Filtered distortion to add brilliance to a signal"

## Syntax

```
ares exciter asig, kfreq, kceil, kharmonics, kblend
```

## Initialization

## Performance

*asig* -- input signal

*kfreq* -- the lower end of the harmonics created.

*kceil* -- the upper end of the harmonics created.

*kharmonics* -- amount of harmonics in the range 0.1 - 10.

*kblend* -- blend between 2nd and 3rd order harmonics in the range -10 - +10.

*exciter* is a reimplementation of the calf exciter plugin.

## Examples

Here is an example of the exciter opcode. It uses the file *exciter.csd* [examples/exciter.csd].

### Example 231. Example of the exciter opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# exitnow

exitnow — Exit Csound as fast as possible, with no cleaning up.

## Description

In Csound4 calls an exit function to leave Csound as fast as possible. On Csound5 exits back to the driving code.

## Syntax

```
exitnow [ivalue]
```

## Initialisation

Stops Csound on the *initialisation* cycle, returning the result ivalue, which defaults to zero. Note that it is usual for this opcode to be alone in an instrument.

## Examples

Here is an example of the exitnow opcode. It uses the file *exitnow.csd* [examples/exitnow.csd].

### Example 232. Example of the exitnow opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# expcurve

**expcurve** — This opcode implements a formula for generating a normalised exponential curve in range 0 - 1. It is based on the Max / MSP work of Eric Singer (c) 1994.

## Description

Generates an exponential curve in range 0 to 1 of arbitrary steepness. Steepness index equal to or lower than 1.0 will result in Not-a-Number errors and cause unstable behavior.

The formula used to calculate the curve is:

```
(exp(x * log(y))-1) / (y-1)
```

where x is equal to *kindex* and y is equal to *ksteepness*.

## Syntax

```
kout expcurve kindex, ksteepness
```

## Performance

*kindex* -- Index value. Expected range 0 to 1.

*ksteepness* -- Steepness of the generated curve. Values closer to 1.0 result in a straighter line while larger values steepen the curve.

*kout* -- Scaled output.

## Examples

Here is an example of the expcurve opcode. It uses the file *expcurve.csd* [examples/expcurve.csd].

### Example 234. Example of the expcurve opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# expon

expon — Trace an exponential curve between specified points.

## Description

Trace an exponential curve between specified points.

## Syntax

```
ares expon ia, idur, ib  
  
kres expon ia, idur, ib
```

## Initialization

*ia* -- starting value. Zero is illegal for exponentials.

*ib* -- value after *idur* seconds. For exponentials, must be non-zero and must agree in sign with *ia*.

*idur* -- duration in seconds of the segment. A zero or negative value will cause all initialization to be skipped.

## Performance

These units generate control or audio signals whose values can pass through 2 specified points. The *idur* value may or may not equal the instrument's performance time: a shorter performance will truncate the specified pattern, while a longer one will cause the defined segment to continue on in the same direction.

## Examples

Here is an example of the expon opcode. It uses the file *expon.csd* [examples/expon.csd].

### Example 235. Example of the expon opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# exprand

exprand — Exponential distribution random number generator (positive values only).

## Description

Exponential distribution random number generator (positive values only). This is an x-class noise generator.

## Syntax

```
ares exprand klambda  
  
ires exprand klambda  
  
kres exprand klambda
```

## Performance

*klambda* -- lambda parameter for the exponential distribution.

The probability density function of an exponential distribution is an exponential curve, whose mean is  $0.69515/\lambda$ . For more detailed explanation of these distributions, see:

1. C. Dodge - T.A. Jerse 1985. Computer music. Schirmer books. pp.265 - 286
2. D. Lorrain. A panoply of stochastic cannons. In C. Roads, ed. 1989. Music machine . Cambridge, Massachusetts: MIT press, pp. 351 - 379.

## Examples

Here is an example of the exprand opcode. It uses the file *exprand.csd* [examples/exprand.csd].

# exprandi

**exprandi** — Exponential distribution random number generator with interpolation (positive values only).

## Description

Exponential distribution random number generator with controlled interpolation between values (positive values only). This is an x-class noise generator.

## Syntax

```
ares exprandi klambda, xamp, xcps  
  
ires exprandi klambda, xamp, xcps  
  
kres exprandi klambda, xamp, xcps
```

## Performance

*klambda* -- lambda parameter for the exponential distribution.

The probability density function of an exponential distribution is an exponential curve, whose mean is  $0.69515/\lambda$ . For more detailed explanation of these distributions, see:

1. C. Dodge - T.A. Jerse 1985. Computer music. Schirmer books. pp.265 - 286
2. D. Lorrain. A panoply of stochastic cannons. In C. Roads, ed. 1989. Music machine . Cambridge, Massachusetts: MIT press, pp. 351 - 379.

*xamp* -- range over which random numbers are distributed.

*xcps* -- the frequency which new random numbers are generated.

## Examples

Here is an example of the exprandi opcode. It uses the file *exprandi.csd* [examples/exprandi.csd].

### Example 237. Example of the exprandi opcode.

# expseg

`expseg` — Trace a series of exponential segments between specified points.

## Description

Trace a series of exponential segments between specified points.

## Syntax

```
ares expseg ia, idur1, ib [, idur2] [, ic] [...]
```

```
kres expseg ia, idur1, ib [, idur2] [, ic] [...]
```

## Initialization

*ia* -- starting value. Zero is illegal for exponentials.

*ib*, *ic*, etc. -- value after *dur1* seconds, etc. For exponentials, must be non-zero and must agree in sign with *ia*.

*idur1* -- duration in seconds of first segment. A zero or negative value will cause all initialization to be skipped.

*idur2*, *idur3*, etc. -- duration in seconds of subsequent segments. A zero or negative value will terminate the initialization process with the preceding point, permitting the last-defined line or curve to be continued indefinitely in performance. The default is zero.

## Performance

These units generate control or audio signals whose values can pass through 2 or more specified points. The sum of *dur* values may or may not equal the instrument's performance time: a shorter performance will truncate the specified pattern, while a longer one will cause the last-defined segment to continue on in the same direction.

Note that the *expseg* opcode does not operate correctly at audio rate when segments are shorter than a k-period. Try the *expseg.a* opcode instead.

## Examples

Here is an example of the *expseg* opcode. It uses the file *expseg.csd* [examples/expseg.csd].

### Example 238. Example of the *expseg* opcode.

# expsega

`expsega` — An exponential segment generator operating at a-rate.

## Description

An exponential segment generator operating at a-rate. This unit is almost identical to `expseg`, but more precise when defining segments with very short durations (i.e., in a percussive attack phase) at audio rate.

## Syntax

```
ares expsega ia, idur1, ib [, idur2] [, ic] [...]
```

## Initialization

*ia* -- starting value. Zero is illegal.

*ib, ic*, etc. -- value after *idur1* seconds, etc. must be non-zero and must agree in sign with *ia*.

*idur1* -- duration in seconds of first segment. A zero or negative value will cause all initialization to be skipped.

*idur2, idur3*, etc. -- duration in seconds of subsequent segments. A zero or negative value will terminate the initialization process with the preceding point, permitting the last defined line or curve to be continued indefinitely in performance. The default is zero.

## Performance

This unit generate audio signals whose values can pass through two or more specified points. The sum of *dur* values may or may not equal the instrument's performance time. A shorter performance will truncate the specified pattern, while a longer one will cause the last defined segment to continue on in the same direction.

## Examples

Here is an example of the `expsega` opcode. It uses the file `expsega.csd` [examples/expsega.csd].

### Example 239. Example of the `expsega` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# expsegb

`expsegb` — Trace a series of exponential segments between specified absolute points.

## Description

Trace a series of exponential segments between specified absolute points.

## Syntax

```
ares expsegb ia, itim1, ib [, itim2] [, ic] [...]
```

```
kres expsegb ia, itim1, ib [, itim2] [, ic] [...]
```

## Initialization

*ia* -- starting value. Zero is illegal for exponentials.

*ib*, *ic*, etc. -- value at *tim1* seconds, etc. For exponentials, must be non-zero and must agree in sign with *ia*.

*itim1* -- time in seconds of end of first segment.

*itim2*, *itim3*, etc. -- time in seconds of subsequent ends of segments.

## Performance

These units generate control or audio signals whose values can pass through 2 or more specified points. The last *tim* value may or may not equal the instrument's performance time: a shorter performance will truncate the specified pattern, while a longer one will cause the last-defined segment to continue on in the same direction.

Note that the *expsegb* opcode does not operate correctly at audio rate when segments are shorter than a k-period. Try the *expsegba* opcode instead.

## Examples

Here is an example of the *expsegb* opcode. It uses the file *expsegb.csd* [examples/expsegb.csd].

### Example 240. Example of the **expsegb** opcode.

# expsegba

`expsegba` — An exponential segment generator operating at a-rate with absolute times.

## Description

An exponential segment generator operating at a-rate. This unit is almost identical to `expsegb`, but more precise when defining segments with very short durations (i.e., in a percussive attack phase) at audio rate.

## Syntax

```
ares expsegba ia, itim1, ib [, itim2] [, ic] [...]
```

## Initialization

*ia* -- starting value. Zero is illegal.

*ib, ic*, etc. -- value after *itim1* seconds, etc. must be non-zero and must agree in sign with *ia*.

*itim1* -- time in seconds at end of first segment.

*itim2, itim3*, etc. -- time in seconds at the end of subsequent segments.

## Performance

This unit generate audio signals whose values can pass through two or more specified points. The final *tim* value may or may not equal the instrument's performance time. A shorter performance will truncate the specified pattern, while a longer one will cause the last defined segment to continue on in the same direction.

## Examples

Here is an example of the `expsegba` opcode. It uses the file `expsegba.csd` [examples/expsegba.csd].

### Example 241. Example of the `expsegba` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# expsegr

`expsegr` — Trace a series of exponential segments between specified points including a release segment.

## Description

Trace a series of exponential segments between specified points including a release segment.

## Syntax

```
ares expsegr ia, idur1, ib [, idur2] [, ic] [...], irel, iz  
kres expsegr ia, idur1, ib [, idur2] [, ic] [...], irel, iz
```

## Initialization

*ia* -- starting value. Zero is illegal for exponentials.

*ib*, *ic*, etc. -- value after *dur1* seconds, etc. For exponentials, must be non-zero and must agree in sign with *ia*.

*idur1* -- duration in seconds of first segment. A zero or negative value will cause all initialization to be skipped.

*idur2*, *idur3*, etc. -- duration in seconds of subsequent segments. A zero or negative value will terminate the initialization process with the preceding point, permitting the last-defined line or curve to be continued indefinitely in performance. The default is zero.

*irel*, *iz* -- duration in seconds and final value of a note releasing segment.

## Performance

These units generate control or audio signals whose values can pass through 2 or more specified points. The sum of *dur* values may or may not equal the instrument's performance time: a shorter performance will truncate the specified pattern, while a longer one will cause the last-defined segment to continue on in the same direction.

*expsegr* is amongst the Csound “r” units that contain a note-off sensor and release time extender. When each senses an event termination or MIDI noteoff, it immediately extends the performance time of the current instrument by *irel* seconds, and sets out to reach the value *iz* by the end of that period (no matter which segment the unit is in). “r” units can also be modified by MIDI noteoff velocities. For two or more extenders in an instrument, extension is by the greatest period.

You can use other pre-made envelopes which start a release segment upon receiving a note off message, like *linsegr* and *madsr*, or you can construct more complex envelopes using *xratim* and *release*. Note that you don't need to use *xratim* if you are using *expsegr*, since the time is extended automatically.

## Examples

Here is an example of the *expsegr* opcode. It uses the file *expsegr.csd* [examples/expsegr.csd].

### Example 242. Example of the expsegr opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# faustaudio

faustaudio — Instantiates and runs a compiled Faust program.

## Description

Faustaudio will instantiate and run a Faust program compiled with faustcompile.

## Syntax

```
ihandle,a1[,a2,...] faustaudio ifac[,ain1,...]
```

## Initialization

“*ifac*” -- a handle to a compiled Faust program, produced by faustcompile.

“*ihandle*” -- a handle to the Faust DSP instance, which can be used to access its controls with faustctl.

## Performance

“*ain1,...*” -- input signals

“*a1,...*” -- output signals

## Examples

Here is an example of the faustaudio opcode, with a simple program that mixes two inputs:

### Example 243.

```
ifac faustcompile "process=+;", "-vec -lv 1"  
idsp,al faustaudio ifac,ain1,ain2
```

# faustcompile

**faustcompile** — Invokes the just-in-time compiler to produce a instantiable DSP process from a Faust program.

## Description

Faustcompile will compile a Faust program from a string, controlled by various arguments. Multi-line strings are accepted, using {{ }} to enclose the string.

## Syntax

```
ihandle faustcompile Scode, Sargs
```

## Initialization

“*Scode*” -- a string (in double-quotes or enclosed by {{ }}) containing a Faust program.

“*Sargs*” -- a string (in double-quotes or enclosed by {{ }}) containing Faust compiler args.

## Examples

Here is an example of the faustcompile opcode, with a simple program that mixes two inputs:

### Example 244.

```
ihandle faustcompile "process=+;" , "-vec -lv 1"
```

## Credits

Author: Victor Lazzarini, 2013

# faustctl

faustctl — Adjusts a given control in a Faust DSP instance.

## Description

Faustctl will set a given control in a running faust program

## Syntax

```
faustctl idsp, Scontrol, kval
```

## Initialization

“Scontrol” -- a string containing the control name

“idsp” -- a handle to an existing Faust DSP instance

## Performance

“kval” -- value to which the control will be set.

## Examples

Here is an example of the faustctl opcode, with a simple program that adjusts the gain of an input:

### Example 245.

```
idsp, a1 faustgen {  
    gain = hslider("vol", 1, 0, 1, 0.01);  
    process = (_ * gain);  
}, ain1  
faustctl idsp, "vol", 0.5
```

## Credits

Author: Victor Lazzarini, 2013

# faustgen

faustgen — Compiles, Instantiates and runs a compiled Faust program.

## Description

Faustgen will invoke the just-in-time compiler, instantiate and run a Faust program.

## Syntax

```
ihandle,a1[,a2,...] faustgen SCode[,ain1,...]
```

## Initialization

“*Scode*” -- a string containing a Faust program.

“*ihandle*” -- a handle to the Faust DSP instance, which can be used to access its controls with faustctl.

## Performance

“*ain1,...*” -- input signals

“*a1,...*” -- output signals

## Examples

Here is an example of the faustgen opcode, with a simple program that mixes two inputs:

### Example 246.

```
idsp,a1 faustgen "process=+;",ain1,ain2
```

# fareylen

fareylen — returns the length of a Farey Sequence.

## Description

This opcode can be used in conjunction with *GENfarey*. It calculates the length of Farey Sequence  $F_n$ . Its length is given by:  $|F_n| = 1 + \sum_{m=1}^n \phi(m)$  where  $\phi(m)$  is Euler's totient function, which gives the number of integers  $\# m$  that are coprime to  $m$ .

Some values for the length of  $F_n$  given  $n$ :

| <b>n</b> | <b><math>F_n</math></b> |
|----------|-------------------------|
| 1        | 2                       |
| 2        | 3                       |
| 3        | 5                       |
| 4        | 7                       |
| 5        | 11                      |
| 6        | 13                      |
| 7        | 19                      |
| 8        | 23                      |
| 9        | 29                      |
| 10       | 33                      |
| 11       | 43                      |
| 12       | 47                      |
| 13       | 59                      |
| 14       | 65                      |
| 15       | 73                      |
| 16       | 81                      |
| 17       | 97                      |
| 18       | 103                     |
| 19       | 121                     |
| 20       | 129                     |

## Syntax

```
kfl fareylen kfn
```

## Performance

The length of the identified Farey sequence is returned.

*kfn* -- Integer identifying the sequence.

# fareyleni

fareyleni — returns the length of a Farey Sequence.

## Description

This opcode can be used in conjunction with *GENfarey*. It calculates the length of Farey Sequence  $F_n$ . Its length is given by:  $|F_n| = 1 + \sum_{m=1}^n \phi(m)$  where  $\phi(m)$  is Euler's totient function, which gives the number of integers  $\# m$  that are coprime to  $m$ .

Some values for the length of  $F_n$  given  $n$ :

| <b>n</b> | <b><math>F_n</math></b> |
|----------|-------------------------|
| 1        | 2                       |
| 2        | 3                       |
| 3        | 5                       |
| 4        | 7                       |
| 5        | 11                      |
| 6        | 13                      |
| 7        | 19                      |
| 8        | 23                      |
| 9        | 29                      |
| 10       | 33                      |
| 11       | 43                      |
| 12       | 47                      |
| 13       | 59                      |
| 14       | 65                      |
| 15       | 73                      |
| 16       | 81                      |
| 17       | 97                      |
| 18       | 103                     |
| 19       | 121                     |
| 20       | 129                     |

## Syntax

ifl **fareyleni** ifn

## Initialisation

The length of the identified Farey sequence is returned.

*ifn* -- Integer identifying the sequence.

# Examples

Here is an example of the fareyleni opcode. It uses the file *fareyleni.csd* [examples/fareyleni.csd].

## Example 247. Example of the fareyleni opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac      ;;;realtime audio out
;-iadc      ;;;uncomment -iadc for RT audio input as well
; For Non-realtime output leave only the line below:
; -o fareyleni.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32

# fclose

`fclose` — Closes a previously opened file.

## Description

`fclose` can be used to close a file which was opened with `fiopen`.

## Syntax

```
fclose ihandle
```

```
fclose Sfilename
```

## Initialization

*ihandle* -- a number which identifies this file (generated by a previous `fiopen`).

*Sfilename* -- A string in double quotes or string variable with the filename. The full path must be given if the file directory is not in the system PATH and is not present in the current directory.

## Performance

`fclose` closes a file which was previously opened with `fiopen`. `fclose` is only needed if you need to read a file written to during the same csound performance, since only when csound ends a performance does it close and save data in all open files. The opcode `fclose` is useful for instance if you want to save presets within files which you want to be accessible without having to terminate csound.

### Note

If you don't need this functionality it is safer not to call `fclose`, and just let csound close the files when it exits.

If a file closed with `fclose` is being accessed by another opcode (like `fout` or `foutk`), it will be closed later when it is no longer being used.

### Warning

This opcode should be used with care, as the file handle will become invalid, and will cause an init error when an opcode tries to access the closed file.

## Examples

Here is an example of the `fclose` opcode. It uses the file `fclose.csd` [examples/fclose.csd].

### Example 248. Example of the `fclose` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command

line flags.

```
<CsoundSynthesizer>
<CsOptions>

; Select audio/midi flags here according to platform
-odac      ;;;realtime audio out
;-iadc      ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime output leave only the line below:
; -o ficlose.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

# filebit

filebit — Returns the number of bits in each sample in a sound file.

## Description

Returns the number of bits in each sample in a sound file.

## Syntax

```
ir filebit ifilcod [, iallowraw]
```

## Initialization

*ifilcod* -- sound file to be queried

*iallowraw* -- (Optional) Allow raw sound files (default=1)

## Performance

*filebit* returns the number of bits in each sample in the sound file *ifilcod*. In the case of floating point samples the value -1 is returned for floats and -2 for doubles. For non-PCM formats the value is negative, and based on libsndfile's format encoding.

## Examples

Here is an example of the filebit opcode. It uses the file *filebit.csd* [examples/filebit.csd], and *mary.wav* [examples/mary.wav].

### Example 249. Example of the filebit opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out    Audio in
-odac          -iadc      ;;;RT audio I/O
; For Non-realtime output leave only the line below:
; -o filebit.wav -W ;; for file output any platform
</CsOptions>
<CsInstruments>

; Initialize the global variables.
sr = 44100
kr = 4410
ksmps = 10
nchnls = 1

; Instrument #1.
instr 1
; Print out the number of channels in the
; audio file "mary.wav".
ibits filebit "mary.wav"
print ibits
```

```
endin

</CsInstruments>
<CsScore>

; Play Instrument #1 for 1 second.
i 1 0 1
e

</CsScore>
</CsoundSynthesizer>
```

The audio file “mary.wav” is in monoaural CD format, so *filebit*'s output should include a line like this:

```
instr 1: ibits = 16.000
```

# filelen

filelen — Returns the length of a sound file.

## Description

Returns the length of a sound file.

## Syntax

```
ir filelen ifilcod, [iallowraw]
```

## Initialization

*ifilcod* -- sound file to be queried

*iallowraw* -- Allow raw sound files (default=1)

## Performance

*filelen* returns the length of the sound file *ifilcod* in seconds. *filelen* can return the length of convolve and PVOC files if the "allow raw sound file" flag is not zero (it is non-zero by default).

## Examples

Here is an example of the filelen opcode. It uses the file *filelen.csd* [examples/filelen.csd], *fox.wav* [examples/fox.wav], and *kickroll.wav* [examples/kickroll.wav].

### Example 250. Example of the filelen opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
;-odac      ;;;realtime audio out
-iadc      ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime output leave only the line below:
;-o filelen.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1 ; choose between mono or stereo file

ilen   filelen p4 ;calculate length of soundfile
print ilen
ichn filenchnls p4 ;check number of channels
;print ichn

if (ichn == 1) then
```

```
;mono signal
asig diskin2 p4, 1
      outs    asig, asig

else
;stereo signal
al, aR diskin2 p4, .5, 0, 1
      outs    aL, aR

endif

endin
</CsInstruments>
<CsScore>

i 1 0 3 "fox.wav" ;mono signal
i 1 5 2 "kickroll.wav" ;stereo signal

e
</CsScore>
</CsoundSynthesizer>
```

The mono audio file “fox.wav” is 2.8 seconds long, and the stereo file “kickroll.wav” is 0.9 seconds. So *filelen*'s output should include a line for the mono and the stereo file like this:

```
instr 1:  ilen = 2.757
instr 1:  ilen = 0.857
```

# filenchnls

filenchnls — Returns the number of channels in a sound file.

## Description

Returns the number of channels in a sound file.

## Syntax

```
ir filenchnls ifilcod [, iallowraw]
```

## Initialization

*ifilcod* -- sound file to be queried

*iallowraw* -- (Optional) Allow raw sound files (default=1)

## Performance

*filenchnls* returns the number of channels in the sound file *ifilcod*. *filechnl*s can return the number of channels of convolve and PVOC files if the *iallowraw* flag is not zero (it is non-zero by default).

## Examples

Here is an example of the filenchnls opcode. It uses the file *filenchnls.csd*, [examples/filenchnls.csd]*fox.wav* [examples/fox.wav], and *kickroll.wav* [examples/kickroll.wav].

### Example 251. Example of the filenchnls opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
;-odac ;;;realtime audio out
;-iadc ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime output leave only the line below:
;-o filechnls.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1 ; choose between mono or stereo file

ilen   filelen p4 ;calculate length of soundfile
/print ilen
ichn filenchnls  p4 ;check number of channels
/print ichn

if (ichn == 1) then
```

```
;mono signal
asig diskin2 p4, 1
      outs    asig, asig

else
;stereo signal
al, aR diskin2 p4, .5, 0, 1
      outs    aL, aR

endif

endin

# filepeak

`filepeak` — Returns the peak absolute value of a sound file.

## Description

Returns the peak absolute value of a sound file.

## Syntax

```
ir filepeak ifilcod [, ichnl]
```

## Initialization

*ifilcod* -- sound file to be queried

*ichnl* (optional, default=0) -- channel to be used in calculating the peak value. Default is 0.

- *ichnl* = 0 returns peak value of all channels
- *ichnl* > 0 returns peak value of *ichnl*

## Performance

`filepeak` returns the peak absolute value of the sound file *ifilcod*.

## Examples

Here is an example of the `filepeak` opcode. It uses the file *filepeak.csd* [examples/filepeak.csd], and *Church.wav* [examples/Church.wav].

### Example 252. Example of the `filepeak` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac      ;;;realtime audio out

# filesr

`filesr` — Returns the sample rate of a sound file.

## Description

Returns the sample rate of a sound file.

## Syntax

```
ir filesr ifilcod [, iallowraw]
```

## Initialization

*ifilcod* -- sound file to be queried

*iallowraw* -- (Optional) Allow raw sound files (default=1)

## Performance

`filesr` returns the sample rate of the sound file *ifilcod*. `filesr` can return the sample rate of convolve and PVOC files if the *iallowraw* flag is not zero (it is non-zero by default).

## Examples

Here is an example of the `filesr` opcode. It uses the file `filesr.csd` [examples/filesr.csd], and `beats.wav` [examples/beats.wav].

### Example 253. Example of the `filesr` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>

; Select audio/midi flags here according to platform
-odac      ;;;realtime audio out
;-iadc      ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime output leave only the line below:
; -o filesr.wav -W ;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

;after an example from Jonathan Murphy

instr 1
;load sound into an ftable
Sfile    strcpy    "beats.wav"
ilen     filelen   Sfile
isr      filesr    Sfile
```

```
    isamps    = ilen * isr
;adjust the length of the table to be a power of two closest
;to the actual size of the sound
    isize     init      1
loop:
    isize    = isize * 2
    if (isize < isamps) igoto loop
    itab    ftgen      0, 0, isize, 1, Sfile, 0, 0, 0
    prints "sample rate = %f, size = %f\n", isr, isize ;prints them

endin
</CsInstruments>
<CsScore>

i1 0 2
e
</CsScore>
</CsoundSynthesizer>
```

The audio file “beats.wav” was sampled at 44.1 KHz. So *filesr*'s output should include a line like this:

```
sample rate = 44100.000000, size = 131072.000000
```

# filevalid

filevalid — Checks that a file can be used.

## Description

Returns 1 if the sound file is valid, or 0 if not.

## Syntax

```
ir filevalid ifilcod
```

## Initialization

*ifilcod* -- sound file to be queried

## Performance

*filevalid* returns 1 if the sound file *ifilcod* can be used.

## Examples

Here is an example of the *filevalid* opcode. It uses the file *filevalid.csd* [examples/filevalid.csd].

### Example 254. Example of the *filevalid* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac     ;;;realtime audio out
;-iadc    ;;;uncomment -iadc if realtime audio input is needed too

# fillarray

fillarray — Generate a vector with initial values.

## Description

Generate a vector (one-dimensional k-rate array) with a sequence of numeric values.

## Syntax

```
karray[] fillarray ival1, ival2,....ivaln
```

## Initialization

*ival1,...ivaln* -- values to place in the vector.

## Examples

Here is an example of the fillarray opcode. It uses the file *fillarray.csd* [examples/fillarray.csd].

### Example 255. Example of the fillarray opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# fft

fft — Complex-to-complex Fast Fourier Transform.

## Description

Applies a forward Fast Fourier Transform to a complex-valued input 1-dimensional array producing a complex-valued output. The output is another array containing the complex-valued signal, and both arrays are arranged in interleaved real-imaginary format. The output array will have the same size as the input, and the transform size will be equivalent to half of the length of the array. Non-power-of-two transforms are limited to even sizes with not too many factors.

## Syntax

```
kout[] fft kin[]
```

## Performance

*kout[]* -- output array containing the complex-valued output. It will be created if it does not exist.

*kin[]* -- input array containing the complex-valued input.

## Examples

Here is an example of the fft opcode. It uses the file *fft.csd* [examples/fft.csd].

### Example 256. Example of the fft opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## filter2

filter2 — Performs filtering using a transposed form-II digital filter lattice with no time-varying control.

### Description

General purpose custom filter with no time-varying pole control. The filter coefficients implement the following difference equation:

$$(1)*y(n) = b0*x[n] + b1*x[n-1] + \dots + bM*x[n-M] - a1*y[n-1] - \dots - aN*y[n-N]$$

the system function for which is represented by:

$$H(Z) = \frac{B(Z)}{A(Z)} = \frac{b_0 + b_1 Z^{-1} + \dots + b_M Z^{-M}}{1 + a_1 Z^{-1} + \dots + a_N Z^{-N}}$$

### Syntax

```
ares filter2 asig, iM, iN, ib0, ib1, ..., ibM, ia1, ia2, ..., iaN  
kres filter2 ksig, iM, iN, ib0, ib1, ..., ibM, ia1, ia2, ..., iaN
```

### Initialization

At initialization the number of zeros and poles of the filter are specified along with the corresponding zero and pole coefficients. The coefficients must be obtained by an external filter-design application such as Matlab and specified directly or loaded into a table via *GEN01*.

### Performance

The *filter2* opcodes perform filtering using a transposed form-II digital filter lattice with no time-varying control.

Since *filter2* implements generalized recursive filters, it can be used to specify a large range of general DSP algorithms. For example, a digital waveguide can be implemented for musical instrument modeling using a pair of *delayr* and *delayw* opcodes in conjunction with the *filter2* opcode.

### Examples

A first-order linear-phase lowpass FIR filter operating on a k-rate signal:

```
k1 filter2 ksig, 2, 0, 0.5, 0.5 ; k-rate FIR filter
```

Here is another example of the filter2 opcode. It uses the file *filter2.csd* [examples/filter2.csd].

### Example 257. Example of the filter2 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# fin

fin — Read signals from a file at a-rate.

## Description

Read signals from a file at a-rate.

## Syntax

```
fin ifilename, iskipframes, iformat, ain1 [, ain2] [, ain3] [,...]  
fin ifilename, iskipframes, iformat, arr[]
```

## Initialization

*ifilename* -- input file name (can be a string or a handle number generated by *fopen*).

*iskipframes* -- number of frames to skip at the start (every frame contains a sample of each channel)

*iformat* -- a number specifying the input file format for headerless files. If a header is found, this argument is ignored.

- 0 - 32 bit floating points without header
- 1 - 16 bit integers without header

## Performance

*fin* (file input) is the complement of *fout*: it reads a multichannel file to generate audio rate signals. The user must be sure that the number of channels of the input file is the same as the number of *ainX* arguments.

### Note

Please note that since this opcode generates its output using input parameters (on the right side of the opcode), these variables must be initialized before use, otherwise a 'used before defined' error will occur. You can use the *init* opcode for this.

## Examples

Here is an example of the fin opcode. It uses the file *fin.csd* [examples/fin.csd] and *fox.wav* [examples/fox.wav].

### Example 258. Example of the fin opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command

line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac      ;;;realtime audio out

# fini

fini — Read signals from a file at i-rate.

## Description

Read signals from a file at i-rate.

## Syntax

```
fini ifilename, iskipframes, iformat, in1 [, in2] [, in3] [, ...]
```

## Initialization

*filename* -- input file name (can be a string or a handle number generated by *fopen*)

*iskipframes* -- number of frames to skip at the start (every frame contains a sample of each channel)

*iformat* -- a number specifying the input file format. If a header is found, this argument is ignored.

- 0 - floating points in text format (loop; see below)
- 1 - floating points in text format (no loop; see below)
- 2 - 32 bit floating points in binary format (no loop)

## Performance

*fini* is the complement of *fouti* and *foutir*. It reads the values each time the corresponding instrument note is activated. When *iformat* is set to 0 and the end of file is reached, the file pointer is zeroed. This restarts the scan from the beginning. When *iformat* is set to 1 or 2, no looping is enabled and at the end of file the corresponding variables will be filled with zeroes.

### Note

Please note that since this opcode generates its output using input parameters (on the right side of the opcode), these variables must be initialized before use, otherwise a 'used before defined' error will occur. You can use the *init* opcode for this.

# fink

*fink* — Read signals from a file at k-rate.

## Description

Read signals from a file at k-rate.

## Syntax

```
fink ifilename, iskipframes, iformat, kin1 [, kin2] [, kin3] [,...]
```

## Initialization

*filename* -- input file name (can be a string or a handle number generated by *fopen*)

*iskipframes* -- number of frames to skip at the start (every frame contains a sample of each channel)

*iformat* -- a number specifying the input file format. If a header is found, this argument is ignored.

- 0 - 32 bit floating points without header
- 1 - 16 bit integers without header

## Performance

*fink* is the same as *fin* but operates at k-rate.

### Note

Please note that since this opcode generates its output using input parameters (on the right side of the opcode), these variables must be initialized before use, otherwise a 'used before defined' error will occur. You can use the *init* opcode for this.

# fiopen

*fiopen* — Opens a file in a specific mode.

## Description

*fiopen* can be used to open a file in one of the specified modes.

## Syntax

```
ihandle fiopen ifilename, imode
```

## Initialization

*ihandle* -- a number which specifies this file.

*ifilename* -- the output file's name (in double-quotes).

*imode* -- choose the mode of opening the file. *imode* can be a value chosen among the following:

- 0 - open a text file for writing
- 1 - open a text file for reading
- 2 - open a binary file for writing
- 3 - open a binary file for reading

## Performance

*fiopen* opens a file to be used by the *fout* family of opcodes. It is safer to use it in the header section, external to any instruments. It returns a number, *ihandle*, which unequivocally refers to the opened file.

If *fiopen* is called on an already open file, it just returns the same handle again, and does not close the file.

Notice that *fout* and *foutk* can use either a string containing a file pathname, or a handle-number generated by *fiopen*. Whereas, with *fouti* and *foutir*, the target file can be only specified by means of a handle-number.

## Examples

Here is an example of the *fiopen* opcode. It uses the file *fiopen.csd* [examples/fiopen.csd].

### Example 259. Example of the fiopen opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# flanger

flanger — A user controlled flanger.

## Description

A user controlled flanger.

## Syntax

```
ares flanger asig, adel, kfeedback [, imaxd]
```

## Initialization

*imaxd*(optional) -- maximum delay in seconds (needed for initial memory allocation)

## Performance

*asig* -- input signal

*adel* -- delay in seconds

*kfeedback* -- feedback amount (in normal tasks this should not exceed 1, even if bigger values are allowed)

This unit is useful for generating choruses and flangers. The delay must be varied at a-rate, for example by connecting *adel* to an oscillator output. The feedback can vary at k-rate. This opcode is implemented to allow *kr* different than *sr* (else delay could not be lower than *ksmps*) enhancing realtime performance. This unit is very similar to *wguide1*, the only difference is *flanger* does not have the lowpass filter or the requirement that the delay be varied at a-rate.

## Examples

Here is an example of the flanger opcode. It uses the file *flanger.csd* [examples/flanger.csd].

### Example 260. Example of the flanger opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac     ;;;realtime audio out

# flashtxt

flashtxt — Allows text to be displayed from instruments like sliders

## Description

Allows text to be displayed from instruments like sliders etc. (only on Unix and Windows at present)

## Syntax

```
flashtxt iwhich, String
```

## Initialization

*iwhich* -- the number of the window.

*String* -- the string to be displayed.

## Performance

Note that this opcode is not available on Windows due to the implementation of pipes on that system

A window is created, identified by the *iwhich* argument, with the text string displayed. If the text is replaced by a number then the window id deleted. Note that the text windows are globally numbered so different instruments can change the text, and the window survives the instance of the instrument.

## Examples

Here is an example of the flashtxt opcode. It uses the file *flashtxt.csd* [examples/flashtxt.csd].

### Example 261. Example of the flashtxt opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# FLbox

FLbox — A FLTK widget that displays text inside of a box.

## Description

A FLTK widget that displays text inside of a box.

## Syntax

```
ihandle FLbox "label", itype, ifont, isize, iwidth, iheight, ix, iy [, image]
```

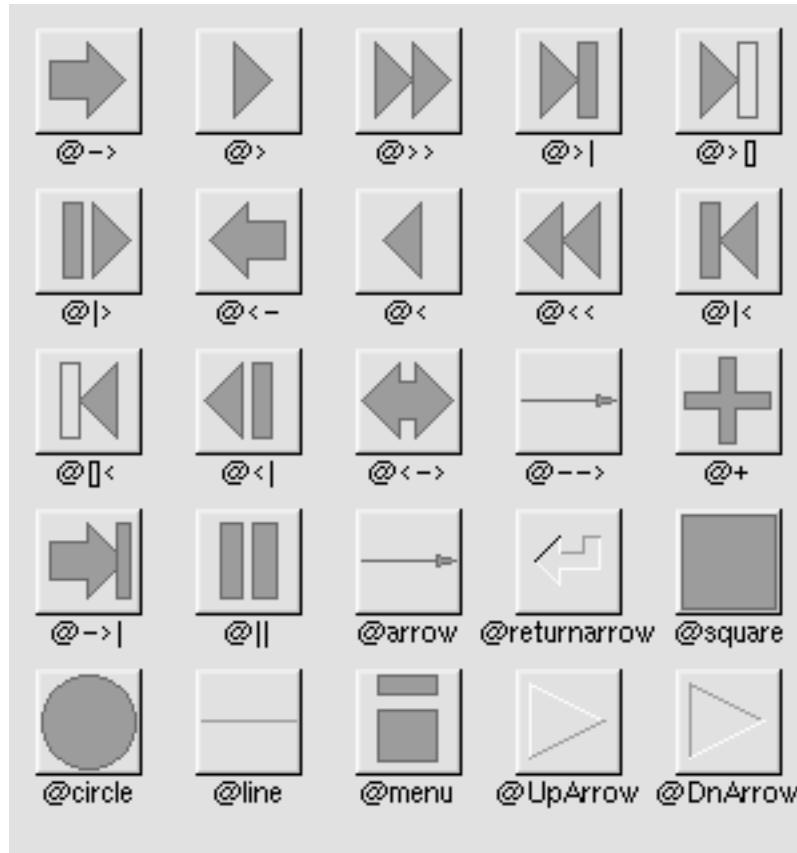

## Initialization

*ihandle* -- a handle value (an integer number) that unequivocally references a corresponding widget. This is used by other opcodes that modify a widget's properties (see *Modifying FLTK Widget Appearance*). It is automatically output by *FLbox* and must not be set by the user label. (The user label is a double-quoted string containing some user-provided text placed near the widget.)

“*label*” -- a double-quoted string containing some user-provided text, placed near corresponding widget.

Notice that with *FLbox*, it is not necessary to call the *FLsetTextType* opcode at all in order to use a symbol. In this case, it is sufficient to set a label starting with “@” followed by the proper formatting string.

The following symbols are supported:

FLTK label supported symbols.

The @ sign may be followed by the following optional “formatting” characters, in this order:

1. “#” forces square scaling rather than distortion to the widget's shape.
2. +[1-9] or -[1-9] tweaks the scaling a little bigger or smaller.
3. [1-9] rotates by a multiple of 45 degrees. “6” does nothing, the others point in the direction of that key on a numeric keypad.

*itype* -- an integer number denoting the appearance of the widget.

The following values are legal for *itype*:

- 1 - flat box
- 2 - up box
- 3 - down box
- 4 - thin up box
- 5 - thin down box
- 6 - engraved box

- 7 - embossed box
- 8 - border box
- 9 - shadow box
- 10 - rounded box
- 11 - rounded box with shadow
- 12 - rounded flat box
- 13 - rounded up box
- 14 - rounded down box
- 15 - diamond up box
- 16 - diamond down box
- 17 - oval box
- 18 - oval shadow box
- 19 - oval flat box

*ifont* -- an integer number denoting the font of *FLbox*.

*ifont* argument to set the font type. The following values are legal for *ifont*:

- 1 - helvetica (same as "Arial" under Windows)
- 2 - helvetica bold
- 3 - helvetica italic
- 4 - helvetica bold italic
- 5 - courier
- 6 - courier bold
- 7 - courier italic
- 8 - courier bold italic
- 9 - times
- 10 - times bold
- 11 - times italic
- 12 - times bold italic
- 13 - symbol
- 14 - screen

- 15 - screen bold
- 16 - dingbats

*isize* -- size of the font.

*iwidth* -- width of widget.

*iheight* -- height of widget.

*ix* -- horizontal position of the upper left corner of the valuator, relative to the upper left corner of corresponding window. (Expressed in pixels.)

*iy* -- vertical position of the upper left corner of the valuator, relative to the upper left corner of corresponding window. (Expressed in pixels.)

*image* -- a handle referring to an eventual image opened with *bmopen* opcode. If it is set, it allows a skin for that widget.

### Note about the *bmopen* opcode

Although the documentation mentions the *bmopen* opcode, it has not been implemented in Csound 4.22.

## Performance

*FLbox* is useful to show some text in a window. The text is bounded by a box, whose aspect depends on *itype* argument.

Note that *FLbox* is not a valuator and its value is fixed. Its value cannot be modified.

## Examples

Here is an example of the *FLbox* opcode. It uses the file *FLbox.csd* [examples/FLbox.csd].

### Example 262. Example of the *FLbox* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# FLbutBank

FLbutBank — A FLTK widget opcode that creates a bank of buttons.

## Description

A FLTK widget opcode that creates a bank of buttons.

## Syntax

```
kout, ihandle FLbutBank itype, inumx, inumy, iwidth, iheight, ix, iy, \
    opcode [, kp1] [, kp2] [, kp3] [, kp4] [, kp5] [....] [, kpN]
```

## Initialization

*ihandle* -- a handle value (an integer number) that unequivocally references a corresponding widget. This is used by other opcodes that modify a widget's properties (see *Modifying FLTK Widget Appearance*). It is automatically output by *FLbutBank* and must not be set by the user label. (The user label is a double-quoted string containing some user-provided text placed near the widget.)

*itype* -- an integer number denoting the appearance of the widget. The valid numbers are:

- 1 - normal button
- 2 - light button
- 3 - check button
- 4 - round button

You can add 20 to the value to create a "plastic" type button. (Note that there is no Plastic Round button. i.e. if you set type to 24 it will look exactly like type 23).

*inumx* -- number of buttons in each row of the bank.

*inumy* -- number of buttons in each column of the bank

*ix* -- horizontal position of upper left corner of the valuator, relative to the upper left corner of corresponding window, expressed in pixels

*-- vertical position of upper left corner of the valuator, relative to the upper left corner of corresponding window, expressed in pixels*

*opcode* -- score opcode type. You have to provide the ascii code of the letter corresponding to the score opcode. At present time only "i" (ascii code 105) score statements are supported. A zero value refers to a default value of "i". So both 0 and 105 activates the *i* opcode. A value of -1 disables this opcode feature.

## Performance

*kout* -- output value

*kp1, kp2, ..., kpN* -- arguments of the activated instruments.

The *FLbutBank* opcode creates a bank of buttons. For example, the following line:

```
gkButton,ihb1  FLbutBank  22, 8, 8, 380, 180, 50, 350, 0, 7, 0, 0, 5000, 6000
```

will create the this bank:

FLbutBank.

A click to a button checks that button. It may also uncheck a previous checked button belonging to the same bank. So the behaviour is always that of radio-buttons. Notice that each button is labeled with a progressive number. The *kout* argument is filled with that number when corresponding button is checked.

*FLbutBank* not only outputs a value but can also activate (or schedule) an instrument provided by the user each time a button is pressed. If the *iopcode* argument is set to a negative number, no instrument is activated so this feature is optional. In order to activate an instrument, *iopcode* must be set to 0 or to 105 (the ascii code of character “i”, referring to the *i* score opcode). P-fields of the activated instrument are *kp1* (instrument number), *kp2* (action time), *kp3* (duration) and so on with user p-fields.

The *itype* argument sets the type of buttons identically to the *FLbutton* opcode. By adding 10 to the *itype* argument (i.e. by setting 11 for type 1, 12 for type 2, 13 for type 3 and 14 for type 4), it is possible to skip the current *FLbutBank* value when getting/setting snapshots (see *General FLTK Widget-related Opcodes*). You can also add 10 to "plastic" button types (31 for type 1, 32 for type 2, etc.)

FLbutBank is very useful to retrieve snapshots.

## Examples

Here is an example of the *FLbutBank* opcode. It uses the file *FLbutBank.csd* [examples/FLbutBank.csd].

### Example 263. Example of the *FLbutBank* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# FLbutton

FLbutton — A FLTK widget opcode that creates a button.

## Description

A FLTK widget opcode that creates a button.

## Syntax

```
kout, ihandle FLbutton "label", ion, ioff, itype, iwidth, iheight, ix, \
iy, iopcode [, kp1] [, kp2] [, kp3] [, kp4] [, kp5] [...] [, kpN]
```

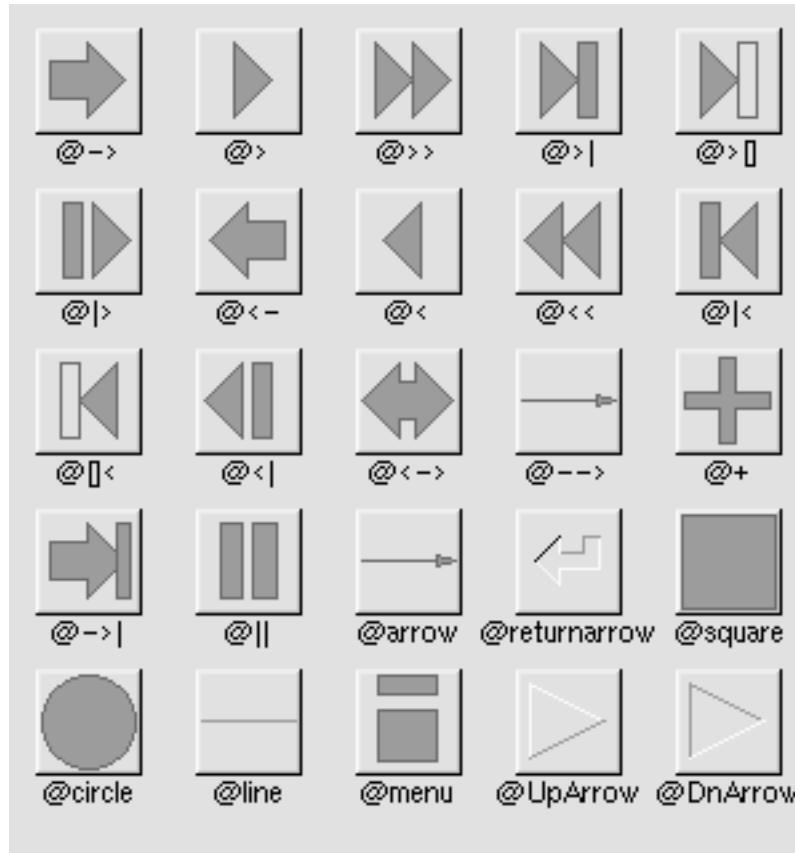

## Initialization

*ihandle* -- a handle value (an integer number) that unequivocally references a corresponding widget. This is used by other opcodes that modify a widget's properties (see *Modifying FLTK Widget Appearance*). It is automatically output by *FLbutton* and must not be set by the user label. (The user label is a double-quoted string containing some user-provided text placed near the widget.)

“*label*” -- a double-quoted string containing some user-provided text, placed near the corresponding widget.

Notice that with *FLbutton*, it is not necessary to call the *FLsetTextType* opcode at all in order to use a symbol. In this case, it is sufficient to set a label starting with “@” followed by the proper formatting string.

The following symbols are supported:

FLTK label supported symbols.

The @ sign may be followed by the following optional “formatting” characters, in this order:

1. “#” forces square scaling rather than distortion to the widget's shape.
2. +[1-9] or -[1-9] tweaks the scaling a little bigger or smaller.
3. [1-9] rotates by a multiple of 45 degrees. “6” does nothing, the others point in the direction of that key on a numeric keypad.

*ion* -- value output when the button is checked.

*ioff* -- value output when the button is unchecked.

*itype* -- an integer number denoting the appearance of the widget.

Several kind of buttons are possible, according to the value of *itype* argument:

- 1 - normal button
- 2 - light button
- 3 - check button
- 4 - round button

You can add 20 to the value to create a "plastic" type button. (Note that there is no Platic Round button. i.e. if you set type to 24 it will look exactly like type 23).

This is the appearance of the buttons:

FLbutton.

*iwidth* -- width of widget.

*iheight* -- height of widget.

*ix* -- horizontal position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*iy* -- vertical position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*iopcode* -- score opcode type. You have to provide the ascii code of the letter corresponding to the score opcode. At present time only "i" (ascii code 105) score statements are supported. A zero value refers to a default value of "i". So both 0 and 105 activates the *i* opcode. A value of -1 disables this opcode feature.

## Performance

*kout* -- output value

*kp1*, *kp2*, ..., *kpN* -- arguments of the activated instruments.

Buttons of type 2, 3, and 4 also output (*kout* argument) the value contained in the *ion* argument when checked, and that contained in *ioff* argument when unchecked.

By adding 10 to *itype* argument (i.e. by setting 11 for type 1, 12 for type 2, 13 for type 3 and 14 for type 4) it is possible to skip the button value when getting/setting snapshots (see later section). *FLbutton* not only outputs a value, but can also activate (or schedule) an instrument provided by the user each time a button is pressed. You can also add 10 to "plastic" button types (31 for type 1, 32 for type 2, etc.)

If the *iopcode* argument is set to a negative number, no instrument is activated. So this feature is optional. In order to activate an instrument, *iopcode* must be set to 0 or to 105 (the ascii code of character “i”, referring to the *i* score opcode).

P-fields of the activated instrument are *kp1* (instrument number), *kp2* (action time), *kp3* (duration) and so on with user p-fields. Notice that in dual state buttons (light button, check button and round button), the instrument is activated only when button state changes from unchecked to checked (not when passing from checked to unchecked).

## Examples

Here is an example of the **FLbutton** opcode. It uses the file *FLbutton.csd* [examples/FLbutton.csd], and *beats.wav* [examples/beats.wav].

### Example 264. Example of the **FLbutton** opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# FLcloseButton

FLcloseButton — A FLTK widget opcode that creates a button that will close the panel window it is a part of.

## Description

A FLTK widget opcode that creates a button that will close the panel window it is a part of.

## Syntax

```
ihandle FLcloseButton "label", iwidth, iheight, ix, iy
```

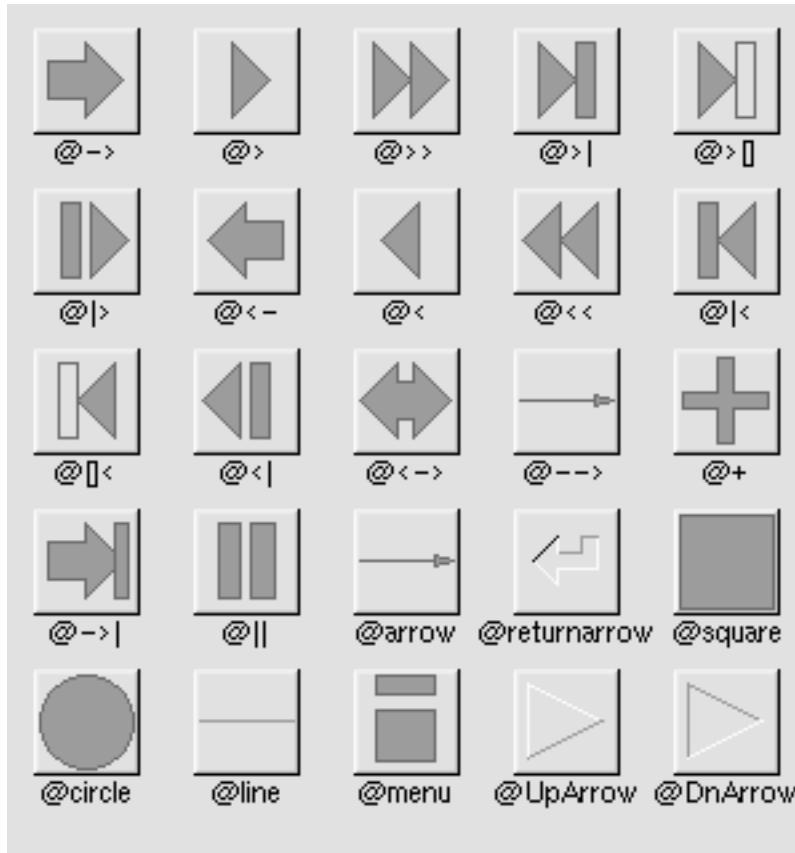

## Initialization

*ihandle* -- a handle value (an integer number) that unequivocally references a corresponding widget. This is used by other opcodes that modify a widget's properties (see *Modifying FLTK Widget Appearance*). It is automatically output by *FLcloseButton* and must not be set by the user label. (The user label is a double-quoted string containing some user-provided text placed near the widget.)

“*label*” -- a double-quoted string containing some user-provided text, placed near the corresponding widget.

Notice that with *FLcloseButton*, it is not necessary to call the *FLsetTextType* opcode at all in order to use a symbol. In this case, it is sufficient to set a label starting with “@” followed by the proper formatting string.

The following symbols are supported:

FLTK label supported symbols.

The @ sign may be followed by the following optional “formatting” characters, in this order:

1. “#” forces square scaling rather than distortion to the widget's shape.
2. +[1-9] or -[1-9] tweaks the scaling a little bigger or smaller.
3. [1-9] rotates by a multiple of 45 degrees. “6” does nothing, the others point in the direction of that key on a numeric keypad.

*iwidth* -- width of widget.

*iheight* -- height of widget.

*ix* -- horizontal position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*iy* -- vertical position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

# FLcolor

**FLcolor** — A FLTK opcode that sets the primary colors.

## Description

Sets the primary colors to RGB values given by the user.

## Syntax

```
FLcolor ired, igreen, iblue [, ired2, igreen2, iblue2]
```

## Initialization

*ired* -- The red color of the target widget. The range for each RGB component is 0-255

*igreen* -- The green color of the target widget. The range for each RGB component is 0-255

*iblue* -- The blue color of the target widget. The range for each RGB component is 0-255

*ired2* -- The red component for the secondary color of the target widget. The range for each RGB component is 0-255

*igreen2* -- The green component for the secondary color of the target widget. The range for each RGB component is 0-255

*iblue2* -- The blue component for the secondary color of the target widget. The range for each RGB component is 0-255

## Performance

These opcodes modify the appearance of other widgets. There are two types of such opcodes, those that don't contain the *ihandle* argument which affect all subsequently declared widgets, and those with *ihandle* which affect only a target widget previously defined.

*FLcolor* sets the primary colors to RGB values given by the user. This opcode affects the primary color of (almost) all widgets defined next its location. User can put several instances of *FLcolor* in front of each widget he intend to modify. However, to modify a single widget, it would be better to use the opcode belonging to the second type (i.e. those containing *ihandle* argument).

*FLcolor* is designed to modify the colors of a group of related widgets that assume the same color. The influence of *FLcolor* on subsequent widgets can be turned off by using -1 as the only argument of the opcode. Also, using -2 (or -3) as the only value of *FLcolor* makes all next widget colors randomly selected. The difference is that -2 selects a light random color, while -3 selects a dark random color.

Using *ired2*, *igreen2*, *iblue2* is equivalent to using a separate *FLcolor2*.

# FLcolor2

FLcolor2 — A FLTK opcode that sets the secondary (selection) color.

## Description

*FLcolor2* is the same of *FLcolor* except it affects the secondary (selection) color.

## Syntax

```
FLcolor2 ired, igreen, iblue
```

## Initialization

*ired* -- The red color of the target widget. The range for each RGB component is 0-255

*igreen* -- The green color of the target widget. The range for each RGB component is 0-255

*iblue* -- The blue color of the target widget. The range for each RGB component is 0-255

## Performance

These opcodes modify the appearance of other widgets. There are two types of such opcodes: those that don't contain the *ihandle* argument which affect all subsequently declared widgets, and those with *ihandle* which affect only a target widget previously defined.

*FLcolor2* is the same of *FLcolor* except it affects the secondary (selection) color. Setting it to -1 turns off the influence of *FLcolor2* on subsequent widgets. A value of -2 (or -3) makes all next widget secondary colors randomly selected. The difference is that -2 selects a light random color, while -3 selects a dark random color.

# FLcount

FLcount — A FLTK widget opcode that creates a counter.

## Description

Allows the user to increase/decrease a value with mouse clicks on a corresponding arrow button.

## Syntax

```
kout, ihandle FLcount "label", imin, imax, istep1, istep2, itype, \
    iwidth, iheight, ix, iy, iopcode [, kp1] [, kp2] [, kp3] [...] [, kpN]
```

## Initialization

*ihandle* -- a handle value (an integer number) that unequivocally references a corresponding widget. Used by further opcodes that changes some valuator's properties. It is automatically set by the corresponding valuator.

“*label*” -- a double-quoted string containing some user-provided text, placed near the corresponding widget.

*imin* -- minimum value of output range

*imax* -- maximum value of output range

*istep1* -- a floating-point number indicating the increment of valuator value corresponding to each mouse click. *istep1* is for fine adjustments.

*istep2* -- a floating-point number indicating the increment of valuator value corresponding to each mouse click. *istep2* is for coarse adjustments.

*itype* -- an integer number denoting the appearance of the valuator.

*iwidth* -- width of widget.

*iheight* -- height of widget.

*ix* -- horizontal position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*-- vertical position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).*

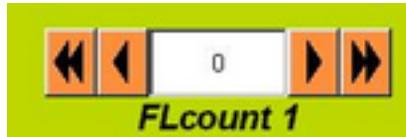

*iopcode* -- score opcode type. You have to provide the ascii code of the letter corresponding to the score opcode. At present time only “i” (ascii code 105) score statements are supported. A zero value refers to a default value of “i”. So both 0 and 105 activates the *i* opcode. A value of -1 disables this opcode feature.

## Performance

*kout* -- output value

*kp1*, *kp2*, ..., *kpN* -- arguments of the activated instruments.

*FLcount* allows the user to increase/decrease a value with mouse clicks on corresponding arrow buttons:

FLcount.

There are two kind of arrow buttons, for larger and smaller steps. Notice that *FLcount* not only outputs a value and a handle, but can also activate (schedule) an instrument provided by the user each time a button is pressed. P-fields of the activated instrument are *kp1* (instrument number), *kp2* (action time), *kp3* (duration) and so on with user p-fields. If the *iopcode* argument is set to a negative number, no instrument is activated. So this feature is optional.

## Examples

Here is an example of the *FLcount* opcode. It uses the file *FLcount.csd* [examples/FLcount.csd].

### Example 265. Example of the **FLcount** opcode.

# FExecButton

FExecButton — A FLTK widget opcode that creates a button that executes a command.

## Description

A FLTK widget opcode that creates a button that executes a command. Useful for opening up HTML documentation as About text or to start a separate program from an FLTK widget interface.

### Warning

Because any command can be executed, the user is advised to be very careful when using this opcode and when running orchestras by others using this opcode.

## Syntax

```
ihandle FExecButton "command", iwidth, iheight, ix, iy
```

## Initialization

*ihandle* -- a handle value (an integer number) that unequivocally references a corresponding widget. This is used by other opcodes that modify a widget's properties (see *Modifying FLTK Widget Appearance*). It is automatically output by *FExecButton*.

“*command*” -- a double-quoted string containing a command to execute.

Notice that with *FExecButton*, the default text for the button is “About” and it is necessary to call the *FLSetText* opcode to change the text of the button.

*iwidth* -- width of widget.

*iheight* -- height of widget.

*ix* -- horizontal position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*iy* -- vertical position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

## Examples

Here is an example of the FExecButton opcode. It uses the file *FExecButton.csd* [examples/FExecButton.csd].

### Example 266. Example of the FExecButton opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# FLgetsnap

`FLgetsnap` — Retrieves a previously stored FLTK snapshot.

## Description

Retrieves a previously stored snapshot (in memory), i.e. sets all valuator to the corresponding values stored in that snapshot.

## Syntax

```
inumsnap FLgetsnap index [, igrup]
```

## Initialization

*inumsnap* -- current number of snapshots.

*index* -- a number referring unequivocally to a snapshot. Several snapshots can be stored in the same bank.

*igrup* -- (optional) an integer number referring to a snapshot-related group of widget. It allows to get/set, or to load/save the state of a subset of valuators. Default value is zero that refers to the first group. The group number is determined by the opcode *FLsetSnapGroup*.

### Note

The *igrup* parameter has not been yet fully implemented in the current version of csound. Please do not rely on it yet.

## Performance

*FLgetsnap* retrieves a previously stored snapshot (in memory), i.e. sets all valuator to the corresponding values stored in that snapshot. The *index* argument unequivocally must refer to an already existing snapshot. If the *index* argument refers to an empty snapshot or to a snapshot that doesn't exist, no action is done. *FLsetsnap* outputs the current number of snapshots (*inumsnap* argument).

For purposes of snapshot saving, widgets can be grouped, so that snapshots affect only a defined group of widgets. The opcode *FLsetSnapGroup* is used to specify the group for all widgets declared after it, until the next *FLsetSnapGroup* statement.

# FLgroup

FLgroup — A FLTK container opcode that groups child widgets.

## Description

A FLTK container opcode that groups child widgets.

## Syntax

```
FLgroup "label", iwidth, iheight, ix, iy [, iborder] [, image]
```

## Initialization

*"label"* -- a double-quoted string containing some user-provided text, placed near the corresponding widget.

*iwidth* -- width of widget.

*iheight* -- height of widget.

*ix* -- horizontal position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*iy* -- vertical position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*iborder* (optional, default=0) -- border type of the container. It is expressed by means of an integer number chosen from the following:

- 0 - no border
- 1 - down box border
- 2 - up box border
- 3 - engraved border
- 4 - embossed border
- 5 - black line border
- 6 - thin down border
- 7 - thin up border

If the integer number doesn't match any of the previous values, no border is provided as the default.

*image* (optional) -- a handle referring to an eventual image opened with the *bmopen* opcode. If it is set, it allows a skin for that widget.

### Note about the **bmopen** opcode

Although the documentation mentions the *bmopen* opcode, it has not been implemented in Csound 4.22.

## Performance

Containers are useful to format the graphic appearance of the widgets. The most important container is *FLpanel*, that actually creates a window. It can be filled with other containers and/or valuators or other kinds of widgets.

There are no k-rate arguments in containers.

## See Also

New in version 4.22

# FLgroupEnd

FLgroupEnd — Marks the end of a group of FLTK child widgets.

## Description

Marks the end of a group of FLTK child widgets.

## Syntax

**FLgroupEnd**

## Performance

Containers are useful to format the graphic appearance of the widgets. The most important container is *FLpanel*, that actually creates a window. It can be filled with other containers and/or valuators or other kinds of widgets.

There are no k-rate arguments in containers.

## FLgroup\_end

FLgroup\_end — Marks the end of a group of FLTK child widgets.

### Description

Marks the end of a group of FLTK child widgets. This is another name for **FLgroupEnd** provides for compatibility. See *FLgroupEnd*

### Credits

Author: Gabriel Maldonado

New in version 4.22

# FLhide

*FLhide* — Hides the target FLTK widget.

## Description

Hides the target FLTK widget, making it invisible.

## Syntax

```
FLhide ihandle
```

## Initialization

*ihandle* -- a handle value (an integer number) that unequivocally references a corresponding widget. This is used by other opcodes that modify a widget's properties (see *Modifying FLTK Widget Appearance*).

## Performance

*FLhide* hides target widget, making it invisible.

## See Also

# FLhvsBox

**FLhvsBox** — Displays a box with a grid useful for visualizing two-dimensional Hyper Vectorial Synthesis.

## Description

*FLhvsBox* displays a box with a grid useful for visualizing two-dimensional Hyper Vectorial Synthesis.

## Syntax

```
ihandle FLhvsBox inumlinesX, inumlinesY, iwidth, iheight, ix, iy
```

## Initialization

*ihandle* – an integer number used a univocally-defined handle for identifying a specific HVS box (see below).

*inumlinesX, inumlinesY* - number of vertical and horizontal lines delimiting the HVS squared areas

*iwidth, iheight* - width and height of the HVS box

*ix, iy* - the position of the HVS box

## Performance

*FLhvsBox* is a widget able to visualize current position of the HVS cursor in an HVS box (i.e. a squared area containing a grid). The number of horizontal and vertical lines of the grid can be defined with the *inumlinesX, inumlinesY* arguments. This opcode has to be declared inside an *FLpanel - FLpanelEnd* block. See the entry for *hvs2* for an example of usage of *FLhvsBox*.

*FLhvsBoxSetValue* is used to set the cursor position of an *FLhvsBox* widget.

## See Also

*hvs2, FLhvsBoxSetValue*

## Credits

Author: Gabriel Maldonado

New in version 5.06

# FLhvsBoxSetValue

`FLhvsBoxSetValue` — Sets the cursor position of a previously-declared `FLhvsBox` widget.

## Description

*FLhvsBoxSetValue* sets the cursor position of a previously-declared *FLhvsBox* widget.

## Syntax

```
FLhvsBox kx, ky, ihandle
```

## Initialization

*ihandle* – an integer number used a univocally-defined handle for identifying a specific HVS box (see below).

## Performance

*kx*, *ky*– the coordinates of the HVS cursor position to be set.

*FLhvsBoxSetValue* sets the cursor position of a previously-declared *FLhvsBox* widget. The *kx* and *ky* arguments, denoting the cursor position, have to be expressed in normalized values (0 to 1 range).

See the entry for *hvs2* for an example of usage of *FLhvsBoxSetValue*.

## See Also

*hvs2*, *FLhvsBox*

New in version 5.06

# FLjoy

FLjoy — A FLTK opcode that acts like a joystick.

## Description

*FLjoy* is a squared area that allows the user to modify two output values at the same time. It acts like a joystick.

## Syntax

```
koutx, kouty, ihandlex, ihandley FLjoy "label", iminx, imaxx, iminy, \
imaxy, iexpx, iexpy, idispox, idispy, iwidth, iheight, ix, iy
```

## Initialization

*ihandlex* -- a handle value (an integer number) that unequivocally references a corresponding widget. Used by further opcodes that changes some valuator's properties. It is automatically set by the corresponding valuator.

*ihandley* -- a handle value (an integer number) that unequivocally references a corresponding widget. Used by further opcodes that changes some valuator's properties. It is automatically set by the corresponding valuator.

“*label*” -- a double-quoted string containing some user-provided text, placed near the corresponding widget.

*iminx* -- minimum x value of output range

*imaxx* -- maximum x value of output range

*iminy* -- minimum y value of output range

*imaxy* -- maximum y value of output range

*iwidth* -- width of widget.

*idispox* -- a handle value that was output from a previous instance of the *FLvalue* opcode to display the current value of the current valuator in the *FLvalue* widget itself. If the user doesn't want to use this feature that displays current values, it must be set to a negative number by the user.

*idispy* -- a handle value that was output from a previous instance of the *FLvalue* opcode to display the current value of the current valuator in the *FLvalue* widget itself. If the user doesn't want to use this feature that displays current values, it must be set to a negative number by the user.

*iexpx* -- an integer number denoting the behaviour of valuator:

- 0 = valuator output is linear
- -1 = valuator output is exponential

All other positive numbers for *iexpx* indicate the number of an existing table that is used for indexing.

Linear interpolation is provided in table indexing. A negative table number suppresses interpolation.

*iexpy* -- an integer number denoting the behaviour of valuator:

- 0 = valuator output is linear
- -1 = valuator output is exponential

All other positive numbers for *iexpy* indicate the number of an existing table that is used for indexing. Linear interpolation is provided in table indexing. A negative table number suppresses interpolation.

## IMPORTANT!

Notice that the tables used by valiators must be created with the *ftgen* opcode and placed in the orchestra before the corresponding valiator. They can not placed in the score. In fact, tables placed in the score are created later than the initialization of the opcodes placed in the header section of the orchestra.

*iheight* -- height of widget.

*ix* -- horizontal position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*iy* -- vertical position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

## Performance

*koutx* -- x output value

*kouty* -- y output value

## Examples

Here is an example of the *FLjoy* opcode. It uses the file *FLjoy.csd* [examples/FLjoy.csd].

# FLkeyIn

FLkeyIn — Reports keys pressed (on alphanumeric keyboard) when an FLTK panel has focus.

## Description

*FLkeyIn* informs about the status of a key pressed by the user on the alphanumeric keyboard when an FLTK panel has got the focus.

## Syntax

```
kascii FLkeyIn [ifn]
```

## Initialization

*ifn* – (optional, default value is zero) set the behavior of FLkeyIn (see below).

## Performance

*kascii* - the ascii value of last pressed key. If the key is pressed, the value is positive, when the key is released the value is negative.

*FLkeyIn* is useful to know whether a key has been pressed on the computer keyboard. The behavior of this opcode depends on the optional *ifn* argument.

If *ifn* = 0 (default), *FLkeyIn* outputs the ascii code of the last pressed key. If it is a special key (ctrl, shift, alt, f1-f12 etc.), a value of 256 is added to the output value in order to distinguish it from normal keys. The output will continue to output the last key value, until a new key is pressed or released. Notice that the output will be negative when a key is depressed.

If *ifn* is set to the number of an already-allocated table having at least 512 elements, then the table element having index equal to the ascii code of the key pressed is set to 1, all other table elements are set to 0. This allows to check the state of a certain key or set of keys.

Be aware that you must set the *ikbdcapture* parameter to something other than 0 on a designated *FLpanel* for *FLkeyIn* to capture keyboard events from that panel.

### Note

*FLkeyIn* works internally at k-rate, so it can't be used in the header as other FLTK opcodes. It must be used inside an instrument.

## Examples

Here is an example of the FLkeyIn opcode. It uses the file *FLkeyIn.csd* [examples/FLkeyIn.csd].

### Example 268. Example of the FLkeyIn opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command

line flags.

# FLknob

FLknob — A FLTK widget opcode that creates a knob.

## Description

A FLTK widget opcode that creates a knob.

## Syntax

```
kout, ihandle FLknob "label", imin, imax, iexp, itype, idisp, iwidth, \
ix, iy [, icursorsize]
```

## Initialization

*ihandle* -- a handle value (an integer number) that unequivocally references a corresponding widget. This is used by other opcodes that modify a widget's properties (see *Modifying FLTK Widget Appearance*). It is automatically output by *FLknob* and must not be set by the user label. (The user label is a double-quoted string containing some user-provided text placed near the widget.)

“*label*” -- a double-quoted string containing some user-provided text, placed near the corresponding widget.

*imin* -- minimum value of output range.

*imax* -- maximum value of output range.

*iexp* -- an integer number denoting the behaviour of valuator:

- 0 = valuator output is linear
- -1 = valuator output is exponential

All other positive numbers for *iexp* indicate the number of an existing table that is used for indexing. Linear interpolation is provided in table indexing. A negative table number suppresses interpolation.

## IMPORTANT!

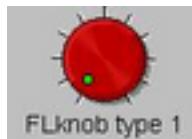

Notice that the tables used by valiators must be created with the *ftgen* opcode and placed in the orchestra before the corresponding valuator. They can not be placed in the score. In fact, tables placed in the score are created later than the initialization of the opcodes placed in the header section of the orchestra.

*itype* -- an integer number denoting the appearance of the valuator.

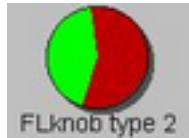

The *itype* argument can be set to the following values:

- 1 - a 3-D knob
- 2 - a pie-like knob

- 3 - a clock-like knob
- 4 - a flat knob

A 3-D knob.

A pie knob.

A clock knob.

A flat knob.

*idisp* -- a handle value that was output from a previous instance of the *FLvalue* opcode to display the current value of the current valuator in the *FLvalue* widget itself. If the user doesn't want to use this feature that displays current values, it must be set to a negative number by the user.

*iwidth* -- width of widget.

*iheight* -- height of widget.

*ix* -- horizontal position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*iy* -- vertical position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*icursorsize* (optional) -- If *FLknob*'s *itype* is set to 1 (3D knob), this parameter controls the size of knob cursor.

## Performance

*kout* -- output value

*FLKnob* puts a knob in the corresponding container.

## Examples

Here is an example of the FLknob opcode. It uses the file *FLknob.csd* [examples/FLknob.csd].

### Example 269. Example of the FLknob opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

New in version 4.22

Example written by Iain McCurdy, edited by Kevin Conder.

# FLabel

**FLabel** — A FLTK opcode that modifies the appearance of a text label.

## Description

Modifies a set of parameters related to the text label appearance of a widget (i.e. size, font, alignment and color of corresponding text).

## Syntax

```
FLabel isize, ifont, ialign, ired, igreen, iblue
```

## Initialization

*isize* -- size of the font of the target widget. Normal values are in the order of 15. Greater numbers enlarge font size, while smaller numbers reduce it.

*ifont* -- sets the font type of the label of a widget.

Legal values for ifont argument are:

- 1 - Helvetica (same as Arial under Windows)
- 2 - Helvetica Bold
- 3 - Helvetica Italic
- 4 - Helvetica Bold Italic
- 5 - Courier
- 6 - Courier Bold
- 7 - Courier Italic
- 8 - Courier Bold Italic
- 9 - Times
- 10 - Times Bold
- 11 - Times Italic
- 12 - Times Bold Italic
- 13 - Symbol
- 14 - Screen
- 15 - Screen Bold
- 16 - Dingbats

*ialign* -- sets the alignment of the label text of the widget.

Legal values for ialign argument are:

- 1 - align center
- 2 - align top
- 3 - align bottom
- 4 - align left
- 5 - align right
- 6 - align top-left
- 7 - align top-right
- 8 - align bottom-left
- 9 - align bottom-right

*ired* -- The red color of the target widget. The range for each RGB component is 0-255

*igreen* -- The green color of the target widget. The range for each RGB component is 0-255

*iblue* -- The blue color of the target widget. The range for each RGB component is 0-255

## Performance

*FLlabel* modifies a set of parameters related to the text label appearance of a widget, i.e. size, font, alignment and color of corresponding text. This opcode affects (almost) all widgets defined next its location. A user can put several instances of *FLlabel* in front of each widget he intends to modify. However, to modify a particular widget, it is better to use the opcode belonging to the second type (i.e. those containing the *ihandle* argument).

The influence of *FLlabel* on the next widget can be turned off by using -1 as its only argument. *FLlabel* is designed to modify text attributes of a group of related widgets.

# FLloadsnap

**FLloadsnap** — Loads all snapshots into the memory bank of the current orchestra.

## Description

*FLloadsnap* loads all the snapshots contained in a file into the memory bank of the current orchestra.

## Syntax

```
FLloadsnap "filename" [, igrup]
```

## Initialization

"*filename*" -- a double-quoted string corresponding to a file to load a bank of snapshots.

*igrup* -- (optional) an integer number referring to a snapshot-related group of widget. It allows to get/set, or to load/save the state of a subset of valuators. Default value is zero that refers to the first group. The group number is determined by the opcode *FLsetSnapGroup*.

### Note

The *igrup* parameter has not been yet fully implemented in the current version of csound. Please do not rely on it yet.

## Performance

*FLloadsnap* loads all snapshots contained in filename into the memory bank of current orchestra.

For purposes of snapshot saving, widgets can be grouped, so that snapshots affect only a defined group of widgets. The opcode *FLsetSnapGroup* is used to specify the group for all widgets declared after it, until the next *FLsetSnapGroup* statement.

# FLmouse

FLmouse — Returns the mouse position and the state of the three mouse buttons.

## Description

*FLmouse* returns the coordinates of the mouse position within an FLTK panel and the state of the three mouse buttons.

## Syntax

```
kx, ky, kb1, kb2, kb3 FLmouse [imode]
```

## Initialization

*imode* – (optional, default = 0) Determines the mode for mouse location reporting.

- 0 - Absolute position normalized to range 0-1
- 1 - Absolute raw pixel position
- 2 - Raw pixel position, relative to FLTK panel

## Performance

*kx, ky* – the mouse coordinates, whose range depends on the *imode* argument (see above).

*kb1, kb2, kb3* – the states of the mouse buttons, 1 when corresponding button is pressed, 0 when the button is not pressed.

*FLmouse* returns the coordinates of the mouse position and the state of the three mouse buttons. The coordinates can be retrieved in three modes depending on the *imode* argument value (see above). Modes 0 and 1 report mouse position in relation to the complete screen (Absolute mode), while mode 2, reports the pixel position within an FLTK panel. Notice that FLmouse is only active when the mouse cursor passes on an *FLpanel* area.

## Examples

Here is an example of the FLmouse opcode. It uses the file *FLmouse.csd* [examples/FLmouse.csd].

### Example 271. Example of the FLmouse opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# flooper

`flooper` — Function-table-based crossfading looper.

## Description

This opcode reads audio from a function table and plays it back in a loop with user-defined start time, duration and crossfade time. It also allows the pitch of the loop to be controlled, including reversed playback. It accepts non-power-of-two tables, such as deferred-allocation GEN01 tables, with one or two channels.

## Syntax

```
asig1[, asig2] flooper kamp, kpitch, istart, idur, ifad, ifn
```

## Initialization

*istart* -- loop start pos in seconds

*idur* -- loop duration in seconds

*ifad* -- crossfade duration in seconds

*ifn* -- function table number, generally created using GEN01

## Performance

*asig[,asig2]* -- output sig (mono or stereo)

*kamp* -- amplitude control

*kpitch* -- pitch control (transposition ratio); negative values play the loop back in reverse

## Examples

### Example 272.

```
aout flooper 16000, 1, 1, 4, 0.05, 1 ; loop starts at 1 sec, for 4 secs, 0.05 crossfade
      out     aout
```

The example above shows the basic operation of *flooper*. Pitch can be controlled at the k-rate, as well as amplitude. The example assumes table 1 to contain at least 5.05 seconds of audio (4 secs loop duration, starting 1 sec into the table, using 0.05 secs after the loop end for the crossfade).

Here is another example of the flooper opcode. It uses the file *flooper.csd* [examples/flooper.csd] and *fox.wav* [examples/fox.wav].

### Example 273.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# flooper2

flooper2 — Function-table-based crossfading looper.

## Description

This opcode implements a crossfading looper with variable loop parameters and three looping modes, optionally using a table for its crossfade shape. It accepts non-power-of-two tables for its source sounds, such as deferred-allocation GEN01 tables, with one or two channels.

## Syntax

```
asig1[,asig2] flooper2 kamp, kpitch, kloopstart, kloopend, kcrossover, ifn \
[, istart, imode, ifenv, iskip]
```

## Initialization

*ifn* -- sound source function table number, generally created using GEN01

*istart* -- playback start pos in seconds

*imode* -- loop modes: 0 forward, 1 backward, 2 back-and-forth [def: 0]

*ifenv* -- if non-zero, crossfade envelope shape table number. The default, 0, sets the crossfade to linear.

*iskip* -- if 1, the opcode initialisation is skipped, for tied notes, performance continues from the position in the loop where the previous note stopped. The default, 0, does not skip initialisation

## Performance

*asig1[, asig2]* -- output sig (mono or stereo).

*kamp* -- amplitude control

*kpitch* -- pitch control (transposition ratio); negative values are not allowed.

*kloopstart* -- loop start point (secs). Note that although k-rate, loop parameters such as this are only updated once per loop cycle.

*kloopend* -- loop end point (secs), updated once per loop cycle.

*kcrossover* -- crossfade length (secs), updated once per loop cycle and limited to loop length.

Mode 1 for *imode* will only loop backwards from the end point to the start point.

## Examples

### Example 274.

```
aout flooper2 16000, 1, 1, 5, 0.05, 1 ; loop starts at 1 sec, for 4 secs, 0.05 crossfade
```

**out**      aout

The example above shows the basic operation of *flooper2*. Pitch can be controlled at the k-rate, as well as amplitude and loop parameters. The example assumes table 1 to contain at least 5.05 seconds of audio (4 secs loop duration, starting 1 sec into the table, using 0.05 secs after the loop end for the crossfade). Looping is in mode 0 (normal forward loop).

Here is another example of the flooper2 opcode. It uses the file *flooper2.csd* [examples/flooper2.csd] and *fox.wav* [examples/fox.wav].

### Example 275.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>

# floor

floor — Returns the largest integer not greater than  $x$

## Description

Returns the largest integer not greater than  $x$

## Syntax

```
floor(x) (init-, control-, or audio-rate arg allowed)
```

where the argument within the parentheses may be an expression. Value converters perform arithmetic translation from units of one kind to units of another. The result can then be a term in a further expression.

## Examples

Here is an example of the floor opcode. It uses the file *floor.csd* [examples/floor.csd].

### Example 276. Example of the floor opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac      ;;;realtime audio out
;-iadc     ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime ouput leave only the line below:
;-o floor.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1

idiv init 1

loop:
inumber = 9
il = inumber / idiv
ifl = floor(il)
print inumber, idiv, ifl ;print number / idiv = result using floor
idiv = idiv + 1
if (idiv <= 10) igoto loop

endin
</CsInstruments>
<CsScore>

i 1 0 0
e

</CsScore>
</CsoundSynthesizer>
```

The output should include lines like these:

```
instr 1: inumber = 9.000 idiv = 1.000 ifl = 9.000
instr 1: inumber = 9.000 idiv = 2.000 ifl = 4.000
instr 1: inumber = 9.000 idiv = 3.000 ifl = 3.000
instr 1: inumber = 9.000 idiv = 4.000 ifl = 2.000
instr 1: inumber = 9.000 idiv = 5.000 ifl = 1.000
instr 1: inumber = 9.000 idiv = 6.000 ifl = 1.000
instr 1: inumber = 9.000 idiv = 7.000 ifl = 1.000
instr 1: inumber = 9.000 idiv = 8.000 ifl = 1.000
instr 1: inumber = 9.000 idiv = 9.000 ifl = 1.000
instr 1: inumber = 9.000 idiv = 10.000 ifl = 0.000
```

# FLpack

FLpack — Provides the functionality of compressing and aligning FLTK widgets.

## Description

*FLpack* provides the functionality of compressing and aligning widgets.

## Syntax

```
FLpack iwidth, iheight, ix, iy, itype, ispace, iborder
```

## Initialization

*iwidth* -- width of widget.

*iheight* -- height of widget.

*ix* -- horizontal position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*iy* -- vertical position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*itype* -- an integer number that modifies the appearance of the target widget.

The *itype* argument expresses the type of packing:

- 0 - vertical
- 1 - horizontal

*ispace* -- sets the space between the widgets.

*iborder* -- border type of the container. It is expressed by means of an integer number chosen from the following:

- 0 - no border
- 1 - down box border
- 2 - up box border
- 3 - engraved border
- 4 - embossed border
- 5 - black line border
- 6 - thin down border
- 7 - thin up border

## Performance

*FLpack* provides the functionality of compressing and aligning widgets.

Containers are useful to format the graphic appearance of the widgets. The most important container is *FLpanel*, that actually creates a window. It can be filled with other containers and/or valiators or other kinds of widgets.

There are no k-rate arguments in containers.

## Examples

The following example:

```
FLpanel "Panel1",450,300,100,100
FLpack 400,300, 10,40,0,15,3
gk1, ihs1   FLslider    "FLslider 1", 500, 1000, 2 ,1, -1, 300,15, 20,50
gk2, ihs2   FLslider    "FLslider 2", 300, 5000, 2 ,3, -1, 300,15, 20,100
gk3, ihs3   FLslider    "FLslider 3", 350, 1000, 2 ,5, -1, 300,15, 20,150
gk4, ihs4   FLslider    "FLslider 4", 250, 5000, 1 ,11, -1, 300,30, 20,200
gk5, ihs5   FLslider    "FLslider 5", 220, 8000, 2 ,1, -1, 300,15, 20,250
gk6, ihs6   FLslider    "FLslider 6", 1, 5000, 1 ,13, -1, 300,15, 20,300
gk7, ihs7   FLslider    "FLslider 7", 870, 5000, 1 ,15, -1, 300,30, 20,350
FLpackEnd
FLpanelEnd
```

...will produce this result, when resizing the window:

FLpack.

# FLpanel

FLpanel — Creates a window that contains FLTK widgets.

## Description

Creates a window that contains FLTK widgets.

## Syntax

```
FLpanel "label", iwidth, iheight [, ix] [, iy] [, iborder] [, ikbdcapture] [, iclose]
```

## Initialization

*"label"* -- a double-quoted string containing some user-provided text, placed near the corresponding widget.

*iwidth* -- width of widget.

*iheight* -- height of widget.

*ix* (optional) -- horizontal position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*iy* (optional) -- vertical position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*iborder* (optional) -- border type of the container. It is expressed by means of an integer number chosen from the following:

- 0 - no border
- 1 - down box border
- 2 - up box border
- 3 - engraved border
- 4 - embossed border
- 5 - black line border
- 6 - thin down border
- 7 - thin up border

*ikbdcapture* (default = 0) -- If this flag is set to 1, keyboard events are captured by the window (for use with *sensekey* and *FLkeyIn*)

*iclose* (default = 0) -- If this flag is set to anything other than 0, the close button of the window is disabled, and the window cannot be closed by the user directly. It will close when csound exits.

## Performance

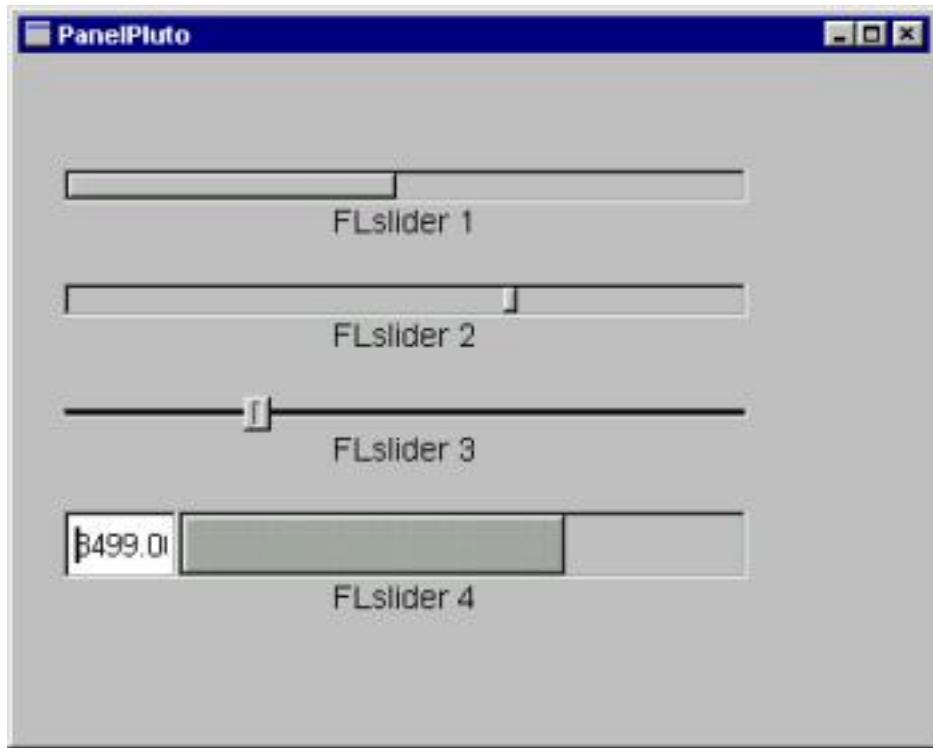

Containers are useful to format the graphic appearance of the widgets. The most important container is *FLpanel*, that actually creates a window. It can be filled with other containers and/or valiators or other kinds of widgets.

There are no k-rate arguments in containers.

*FLpanel* creates a window. It must be followed by the opcode *FLpanelEnd* when all widgets internal to it are declared. For example:

```
FLpanel      "PanelPluto", 450, 550, 100, 100 ;***** start of container
gk1, ih1 FLslider  "FLslider 1", 500, 1000, 2 ,1, -1, 300,15, 20,50
gk2, ih2 FLslider  "FLslider 2", 300, 5000, 2 ,3, -1, 300,15, 20,100
gk3, ih3 FLslider  "FLslider 3", 350, 1000, 2 ,5, -1, 300,15, 20,150
gk4, ih4 FLslider  "FLslider 4", 250, 5000, 1 ,11,-1, 300,30, 20,200
FLpanelEnd ;***** end of container
```

will output the following result:

FLpanel.

If the *ikbdcapture* flag is set, the window captures keyboard events, and sends them to all *sensekey*. This flag modifies the behavior of *sensekey*, and makes it receive events from the FLTK window instead of *stdin*.

## Examples

Here is an example of the *FLpanel* opcode. It uses the file *FLpanel.csd* [examples/FLpanel.csd].

**Example 277. Example of the FLpanel opcode.**

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# FLprintk

**FLprintk** — A FLTK opcode that prints a k-rate value at specified intervals.

## Description

*FLprintk* is similar to *printf* but shows values of a k-rate signal in a text field instead of on the console.

## Syntax

```
FLprintk itime, kval, idisp
```

## Initialization

*itime* -- how much time in seconds is to elapse between updated displays.

*idisp* -- a handle value that was output from a previous instance of the *FLvalue* opcode to display the current value of the current valuator in the *FLvalue* widget itself. If the user doesn't want to use this feature that displays current values, it must be set to a negative number by the user.

## Performance

*kval* -- k-rate signal to be displayed.

*FLprintk* is similar to *printf*, but shows values of a k-rate signal in a text field instead of showing it in the console. The *idisp* argument must be filled with the *ihandle* return value of a previous *FLvalue* opcode. While *FLvalue* should be placed in the header section of an orchestra inside an *FLpanel/FLpanelEnd* block, *FLprintk* must be placed inside an instrument to operate correctly. For this reason, it slows down performance and should be used for debugging purposes only.

## See Also

*FLbox*, *FLbutBank*, *FLbutton*, *FLprintk2*, *FLvalue*

## Credits

Author: Gabriel Maldonado

New in version 4.22

# FLprintk2

*FLprintk2* — A FLTK opcode that prints a new value every time a control-rate variable changes.

## Description

*FLprintk2* is similar to *FLprintk* but shows a k-rate variable's value only when it changes.

## Syntax

```
FLprintk2 kval, idisp
```

## Initialization

*idisp* -- a handle value that was output from a previous instance of the *FLvalue* opcode to display the current value of the current valuator in the *FLvalue* widget itself. If the user doesn't want to use this feature that displays current values, it must be set to a negative number by the user.

## Performance

*kval* -- k-rate signal to be displayed.

*FLprintk2* is similar to *FLprintk*, but shows the k-rate variable's value only each time it changes. Useful for monitoring MIDI control changes when using sliders. It should be used for debugging purposes only, since it slows-down performance.

## See Also

*FLbox*, *FLbutBank*, *FLbutton*, *FLprintk*, *FLvalue*

# FLroller

FLroller — A FLTK widget that creates a transversal knob.

## Description

*FLroller* is a sort of knob, but put transversally.

## Syntax

```
kout, ihandle FLroller "label", imin, imax, istep, iexp, itype, idisp, \
iwidth, iheight, ix, iy
```

## Initialization

*ihandle* -- a handle value (an integer number) that unequivocally references a corresponding widget. This is used by other opcodes that modify a widget's properties (see *Modifying FLTK Widget Appearance*). It is automatically output by *FLroller* and must not be set by the user label. (The user label is a double-quoted string containing some user-provided text placed near the widget.)

*"label"* -- a double-quoted string containing some user-provided text, placed near the corresponding widget.

*imin* -- minimum value of output range.

*imax* -- maximum value of output range.

*istep* -- a floating-point number indicating the increment of valuator value corresponding to each mouse click. The *istep* argument allows the user to arbitrarily slow roller's motion, enabling arbitrary precision.

*iexp* -- an integer number denoting the behaviour of valuator:

- 0 = valuator output is linear
- -1 = valuator output is exponential

All other positive numbers for *iexp* indicate the number of an existing table that is used for indexing. Linear interpolation is provided in table indexing. A negative table number suppresses interpolation.

### IMPORTANT!

Notice that the tables used by valuators must be created with the *ftgen* opcode and placed in the orchestra before the corresponding valuator. They can not be placed in the score. In fact, tables placed in the score are created later than the initialization of the opcodes placed in the header section of the orchestra.

*itype* -- an integer number denoting the appearance of the valuator.

The *itype* argument can be set to the following values:

- 1 - horizontal roller
- 2 - vertical roller

*iwidth* -- a handle value that was output from a previous instance of the *FLvalue* opcode to display the current value of the current valuator in the *FLvalue* widget itself. If the user doesn't want to use this feature that displays current values, it must be set to a negative number by the user.

*iwidth* -- width of widget.

*iheight* -- height of widget.

*ix* -- horizontal position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*iy* -- vertical position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

## Performance

*kout* -- output value

*FLroller* is a sort of knob, but put transversally:

FLroller.

## Examples

Here is an example of the *FLroller* opcode. It uses the file *FLroller.csd* [examples/FLroller.csd].

### Example 278. Example of the **FLroller** opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

Example written by Iain McCurdy, edited by Kevin Conder.

# FLrun

FLrun — Starts the FLTK widget thread.

## Description

Starts the FLTK widget thread.

## Syntax

**FLrun**

## Performance

This opcode must be located at the end of all widget declarations. It has no arguments, and its purpose is to start the thread related to widgets. Widgets would not operate if *FLrun* is missing.

## See Also

*FLgetsnap*, *FLloadsnap*, *FLsavesnap*, *FLsetsnap*, *FLupdate*

# FLsavesnap

FLsavesnap — Saves all snapshots currently created into a file.

## Description

*FLsavesnap* saves all snapshots currently created (i.e. the entire memory bank) into a file.

## Syntax

```
FLsavesnap "filename" [, igrup]
```

## Initialization

“*filename*” -- a double-quoted string corresponding to a file to store a bank of snapshots.

*igrup* -- (optional) an integer number referring to a snapshot-related group of widget. It allows to get/set, or to load/save the state of a subset of valuators. Default value is zero that refers to the first group. The group number is determined by the opcode *FLsetSnapGroup*.

### Note

The *igrup* parameter has not been yet fully implemented in the current version of csound. Please do not rely on it yet.

## Performance

*FLsavesnap* saves all snapshots currently created (i.e. the entire memory bank) into a file whose name is *filename*. Since the file is a text file, snapshot values can also be edited manually by means of a text editor. The format of the data stored in the file is the following (at present time, this could be changed in next Csound version):

```
----- 0 -----
FLvalue 0 0 1 0 ""
FLvalue 0 0 1 0 ""
FLvalue 0 0 1 0 ""
FLslider 331.946 80 5000 -1 "frequency of the first oscillator"
FLslider 385.923 80 5000 -1 "frequency of the second oscillator"
FLslider 80 80 5000 -1 "frequency of the third oscillator"
FLcount 0 0 10 0 "this index must point to the location number where snapshot is stored"
FLbutton 0 0 1 0 "Store snapshot to current index"
FLbutton 0 0 1 0 "Save snapshot bank to disk"
FLbutton 0 0 1 0 "Load snapshot bank from disk"
FLbox 0 0 1 0 ""
----- 1 -----
FLvalue 0 0 1 0 ""
FLvalue 0 0 1 0 ""
FLvalue 0 0 1 0 ""
FLslider 819.72 80 5000 -1 "frequency of the first oscillator"
FLslider 385.923 80 5000 -1 "frequency of the second oscillator"
FLslider 80 80 5000 -1 "frequency of the third oscillator"
FLcount 1 0 10 0 "this index must point to the location number where snapshot is stored"
FLbutton 0 0 1 0 "Store snapshot to current index"
FLbutton 0 0 1 0 "Save snapshot bank to disk"
FLbutton 0 0 1 0 "Load snapshot bank from disk"
FLbox 0 0 1 0 ""
----- 2 -----
```

```
..... etc...  
----- 3 -----  
..... etc...  
-----
```

As you can see, each snapshot contain several lines. Each snapshot is separated from previous and next snapshot by a line of this kind:

```
"----- snapshot Num -----"
```

Then there are several lines containing data. Each of these lines corresponds to a widget.

The first field of each line is an unquoted string containing opcode name corresponding to that widget. Second field is a number that expresses current value of a snapshot. In current version, this is the only field that can be modified manually. The third and fourth fields shows minimum and maximum values allowed for that valuator. The fifth field is a special number that indicates if the valuator is linear (value 0), exponential (value -1), or is indexed by a table interpolating values (negative table numbers) or non-interpolating (positive table numbers). The last field is a quoted string with the label of the widget. Last line of the file is always

```
"-----"
```

Note that *FLvalue* and *FLbox* are not valuators and their values are fixed, so they cannot be modified.

For purposes of snapshot saving, widgets can be grouped, so that snapshots affect only a defined group of widgets. The opcode *FLsetSnapGroup* is used to specify the group for all widgets declared after it, until the next *FLsetSnapGroup* statement.

## Examples

Here is a simple example of the FLTK snapshot saving. It uses the file *FLsavesnap\_simple.csd* [examples/FLsavesnap\_simple.csd].

### Example 279. Example of FLTK snapshot saving.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# FLscroll

FLscroll — A FLTK opcode that adds scroll bars to an area.

## Description

*FLscroll* adds scroll bars to an area.

## Syntax

```
FLscroll iwidth, iheight [, ix] [, iy]
```

## Initialization

*iwidth* -- width of widget.

*iheight* -- height of widget.

*ix* (optional) -- horizontal position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*iy* (optional) -- vertical position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

## Performance

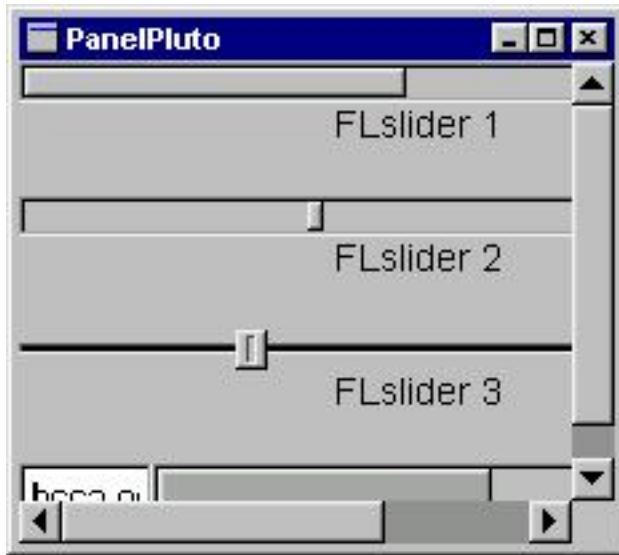

Containers are useful to format the graphic appearance of the widgets. The most important container is *FLpanel*, that actually creates a window. It can be filled with other containers and/or valuators or other kinds of widgets.

There are no k-rate arguments in containers.

*FLscroll* adds scroll bars to an area. Normally you must set arguments *iwidth* and *iheight* equal to that of the parent window or other parent container. *ix* and *iy* are optional since they normally are set to zero. For example the following code:

```
FLpanel "PanelPluto",400,300,100,100
FLscroll 400,300
gk1, ih1 FLslider "FLslider 1", 500, 1000, 2 ,1, -1, 300,15, 20,50
gk2, ih2 FLslider "FLslider 2", 300, 5000, 2 ,3, -1, 300,15, 20,100
gk3, ih3 FLslider "FLslider 3", 350, 1000, 2 ,5, -1, 300,15, 20,150
gk4, ih4 FLslider "FLslider 4", 250, 5000, 1 ,11,-1, 300,30, 20,200
FLscrollEnd
FLpanelEnd
```

will show scroll bars, when the main window size is reduced:

FLscroll.

## Examples

Here is an example of the FLscroll opcode. It uses the file *FLscroll.csd* [examples/FLscroll.csd].

### Example 281. Example of the FLscroll opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# FLscrollEnd

FLscrollEnd — A FLTK opcode that marks the end of an area with scrollbars.

## Description

A FLTK opcode that marks the end of an area with scrollbars.

## Syntax

`FLscrollEnd`

## Performance

Containers are useful to format the graphic appearance of the widgets. The most important container is *FLpanel*, that actually creates a window. It can be filled with other containers and/or valuators or other kinds of widgets.

There are no k-rate arguments in containers.

## See Also

# FLsetAlign

FLsetAlign — Sets the text alignment of a label of a FLTK widget.

## Description

*FLsetAlign* sets the text alignment of the label of the target widget.

## Syntax

```
FLsetAlign ialign, ihandle
```

## Initialization

*ialign* -- sets the alignment of the label text of widgets.

The legal values for the *ialign* argument are:

- 1 - align center
- 2 - align top
- 3 - align bottom
- 4 - align left
- 5 - align right
- 6 - align top-left
- 7 - align top-right
- 8 - align bottom-left
- 9 - align bottom-right

*ihandle* -- an integer number (used as unique identifier) taken from the output of a previously located widget opcode (which corresponds to the target widget). It is used to unequivocally identify the widget when modifying its appearance with this class of opcodes. The user must not set the *ihandle* value directly, otherwise a Csound crash will occur.

# FLsetBox

FLsetBox — Sets the appearance of a box surrounding a FLTK widget.

## Description

*FLsetBox* sets the appearance of a box surrounding the target widget.

## Syntax

```
FLsetBox itype, ihandle
```

## Initialization

*itype* -- an integer number that modify the appearance of the target widget.

Legal values for the *itype* argument are:

- 1 - flat box
- 2 - up box
- 3 - down box
- 4 - thin up box
- 5 - thin down box
- 6 - engraved box
- 7 - embossed box
- 8 - border box
- 9 - shadow box
- 10 - rounded box
- 11 - rounded box with shadow
- 12 - rounded flat box
- 13 - rounded up box
- 14 - rounded down box
- 15 - diamond up box
- 16 - diamond down box
- 17 - oval box
- 18 - oval shadow box

- 19 - oval flat box

*ihandle* -- an integer number (used as unique identifier) taken from the output of a previously located widget opcode (which corresponds to the target widget). It is used to unequivocally identify the widget when modifying its appearance with this class of opcodes. The user must not set the *ihandle* value directly, otherwise a Csound crash will occur.

# FLsetColor

FLsetColor — Sets the primary color of a FLTK widget.

## Description

*FLsetColor* sets the primary color of the target widget.

## Syntax

```
FLsetColor ired, igreen, iblue, ihandle
```

## Initialization

*ired* -- The red color of the target widget. The range for each RGB component is 0-255

*igreen* -- The green color of the target widget. The range for each RGB component is 0-255

*iblue* -- The blue color of the target widget. The range for each RGB component is 0-255

*ihandle* -- an integer number (used as unique identifier) taken from the output of a previously located widget opcode (which corresponds to the target widget). It is used to unequivocally identify the widget when modifying its appearance with this class of opcodes. The user must not set the *ihandle* value directly, otherwise a Csound crash will occur.

## Examples

Here is an example of the FLsetColor opcode. It uses the file *FLsetcolor.csd* [examples/FLsetcolor.csd].

### Example 282. Example of the FLsetColor opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# FLsetColor2

FLsetColor2 — Sets the secondary (or selection) color of a FLTK widget.

## Description

*FLsetColor2* sets the secondary (or selection) color of the target widget.

## Syntax

```
FLsetColor2 ired, igreen, iblue, ihandle
```

## Initialization

*ired* -- The red color of the target widget. The range for each RGB component is 0-255

*igreen* -- The green color of the target widget. The range for each RGB component is 0-255

*iblue* -- The blue color of the target widget. The range for each RGB component is 0-255

*ihandle* -- an integer number (used as unique identifier) taken from the output of a previously located widget opcode (which corresponds to the target widget). It is used to unequivocally identify the widget when modifying its appearance with this class of opcodes. The user must not set the *ihandle* value directly, otherwise a Csound crash will occur.

# FLSetFont

FLSetFont — Sets the font type of a FLTK widget.

## Description

*FLSetFont* sets the font type of the target widget.

## Syntax

```
FLSetFont ifont, ihandle
```

## Initialization

*ifont* -- sets the the font type of the label of a widget.

Legal values for *ifont* argument are:

- 1 - Helvetica (same as Arial under Windows)
- 2 - Helvetica Bold
- 3 - Helvetica Italic
- 4 - Helvetica Bold Italic
- 5 - Courier
- 6 - Courier Bold
- 7 - Courier Italic
- 8 - Courier Bold Italic
- 9 - Times
- 10 - Times Bold
- 11 - Times Italic
- 12 - Times Bold Italic
- 13 - Symbol
- 14 - Screen
- 15 - Screen Bold
- 16 - Dingbats

*ihandle* -- an integer number (used as unique identifier) taken from the output of a previously located widget opcode (which corresponds to the target widget). It is used to unequivocally identify the widget when modifying its appearance with this class of opcodes. The user must not set the *ihandle* value dir-

ectly, otherwise a Csound crash will occur.

# FLsetPosition

`FLsetPosition` — Sets the position of a FLTK widget.

## Description

*FLsetPosition* sets the position of the target widget according to the *ix* and *iy* arguments.

## Syntax

```
FLsetPosition ix, iy, ihandle
```

## Initialization

*ix* -- horizontal position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*iy* -- vertical position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*ihandle* -- an integer number (used as unique identifier) taken from the output of a previously located widget opcode (which corresponds to the target widget). It is used to unequivocally identify the widget when modifying its appearance with this class of opcodes. The user must not set the *ihandle* value directly, otherwise a Csound crash will occur.

# FLsetSize

`FLsetSize` — Resizes a FLTK widget.

## Description

*FLsetSize* resizes the target widget (not the size of its text) according to the *iwidth* and *iheight* arguments.

## Syntax

```
FLsetSize iwidth, iheight, ihandle
```

## Initialization

*iwidth* -- width of widget.

*iheight* -- height of widget.

*ihandle* -- an integer number (used as unique identifier) taken from the output of a previously located widget opcode (which corresponds to the target widget). It is used to unequivocally identify the widget when modifying its appearance with this class of opcodes. The user must not set the *ihandle* value directly, otherwise a Csound crash will occur.

# FLsetsnap

**FLsetsnap** — Stores the current status of all FLTK valiators into a snapshot location.

## Description

*FLsetsnap* stores the current status of all valiators present in the orchestra into a snapshot location (in memory).

## Syntax

```
inumsnap, inumval FLsetsnap index [, ifn, igrup]
```

## Initialization

*inumsnap* -- current number of snapshots.

*inumval* -- number of valiators (whose value is stored in a snapshot) present in current orchestra.

*index* -- a number referring unequivocally to a snapshot. Several snapshots can be stored in the same bank.

*ifn* (optional) -- optional argument referring to an already allocated table, to store values of a snapshot.

*igrup* -- (optional) an integer number referring to a snapshot-related group of widget. It allows to get/set, or to load/save the state of a subset of valiators. Default value is zero that refers to the first group. The group number is determined by the opcode *FLsetSnapGroup*.

### Note

The *igrup* parameter has not been yet fully implemented in the current version of csound. Please do not rely on it yet.

## Performance

The *FLsetsnap* opcode stores current status of all valiators present in the orchestra into a snapshot location (in memory). Any number of snapshots can be stored in the current bank. Banks are structures that only exist in memory, there are no other reference to them other than they can be accessed by *FLsetsnap*, *FLsavesnap*, *FLloadsnap* and *FLgetsnap* opcodes. Only a single bank can be present in memory.

If the optional *ifn* argument refers to an already allocated and valid table, the snapshot will be stored in the table instead of in the bank. So that table can be accessed from other Csound opcodes.

The *index* argument unequivocally refers to a determinate snapshot. If the value of *index* refers to a previously stored snapshot, all its old values will be replaced with current ones. If *index* refers to a snapshot that doesn't exist, a new snapshot will be created. If the *index* value is not adjacent with that of a previously created snapshot, some empty snapshots will be created. For example, if a location with *index* 0 contains the only and unique snapshot present in a bank and the user stores a new snapshot using *index* 5, all locations between 1 and 4 will automatically contain empty snapshots. Empty snapshots don't contain any data and are neutral.

*FLsetsnap* outputs the current number of snapshots (the *inumsnap* argument) and the total number of

values stored in each snapshot (*inumval*). *inumval* is equal to the number of valiators present in the orchestra.

For purposes of snapshot saving, widgets can be grouped, so that snapshots affect only a defined group of widgets. The opcode *FLsetSnapGroup* is used to specify the group for all widgets declared after it, until the next *FLsetSnapGroup* statement.

# FLsetSnapGroup

FLsetSnapGroup — Determines the snapshot group for FL valuators.

## Description

*FLsetSnapGroup* determines the snapshot group of valuators declared after it.

## Syntax

```
FLsetSnapGroup igrp
```

## Initialization

*igrp* -- (optional) an integer number referring to a snapshot-related group of widget. It allows to get/set, or to load/save the state of a subset of valuators.

### Note

The *igrp* parameter has not been yet fully implemented in the current version of csound. Please do not rely on it yet.

## Performance

For purposes of snapshot saving, widgets can be grouped, so that snapshots affect only a defined group of widgets. The opcode *FLsetSnapGroup* is used to specify the group for all widgets declared after it, until the next *FLsetSnapGroup* statement.

*FLsetSnapGroup* determines the snapshot group of a declared valuator. To make a valuator belong to a stated group, you have to place *FLsetSnapGroup* just before the declaration of the widget itself. The group stated by *FLsetSnapGroup* lasts for all valuators declared after it, until a new *FLsetSnapGroup* statement with a different group is encountered. If no *FLsetSnapGroup* statement are present in an orchestra, the default group for all widgets will be group zero.

# FLSetText

FLSetText — Sets the label of a FLTK widget.

## Description

*FLSetText* sets the label of the target widget to the double-quoted text string provided with the *itext* argument.

## Syntax

```
FLSetText "itext", ihandle
```

## Initialization

“*itext*” -- a double-quoted string denoting the text of the label of the widget.

*ihandle* -- an integer number (used as unique identifier) taken from the output of a previously located widget opcode (which corresponds to the target widget). It is used to unequivocally identify the widget when modifying its appearance with this class of opcodes. The user must not set the *ihandle* value directly, otherwise a Csound crash will occur.

## Examples

Here is an example of the FLSetText opcode. It uses the file *FLSetText.csd* [examples/FLSetText.csd].

### Example 283. Example of the FLSetText opcode.

# FLsetTextColor

`FLsetTextColor` — Sets the color of the text label of a FLTK widget.

## Description

*FLsetColor* sets the color of the text label of the target widget.

## Syntax

```
FLsetTextColor ired, iblue, igreen, ihandle
```

## Initialization

*ired* -- The red color of the target widget. The range for each RGB component is 0-255

*igreen* -- The green color of the target widget. The range for each RGB component is 0-255

*iblue* -- The blue color of the target widget. The range for each RGB component is 0-255

*ihandle* -- an integer number (used as unique identifier) taken from the output of a previously located widget opcode (which corresponds to the target widget). It is used to unequivocally identify the widget when modifying its appearance with this class of opcodes. The user must not set the *ihandle* value directly, otherwise a Csound crash will occur.

## See Also

# FLsetTextSize

`FLsetTextSize` — Sets the size of the text label of a FLTK widget.

## Description

*FLsetTextSize* sets the size of the text label of the target widget.

## Syntax

```
FLsetTextSize isize, ihandle
```

## Initialization

*isize* -- size of the font of the target widget. Normal values are in the order of 15. Greater numbers enlarge font size, while smaller numbers reduce it.

*ihandle* -- an integer number (used as unique identifier) taken from the output of a previously located widget opcode (which corresponds to the target widget). It is used to unequivocally identify the widget when modifying its appearance with this class of opcodes. The user must not set the *ihandle* value directly, otherwise a Csound crash will occur.

## See Also

*FLcolor2, FLhide, FLlabel, FLsetAlign, FLsetBox, FLsetColor, FLsetColor2, FLsetFont, FLsetPosition, FLsetSize, FLsetText, FLsetTextColor, FLsetTextSize, FLsetTextType, FLsetVal\_i, FLsetVal, FLshow*

## Credits

New in version 4.22

# FLsetTextType

FLsetTextType — Sets some font attributes of the text label of a FLTK widget.

## Description

*FLsetTextType* sets some attributes related to the fonts of the text label of the target widget.

## Syntax

```
FLsetTextType itype, ihandle
```

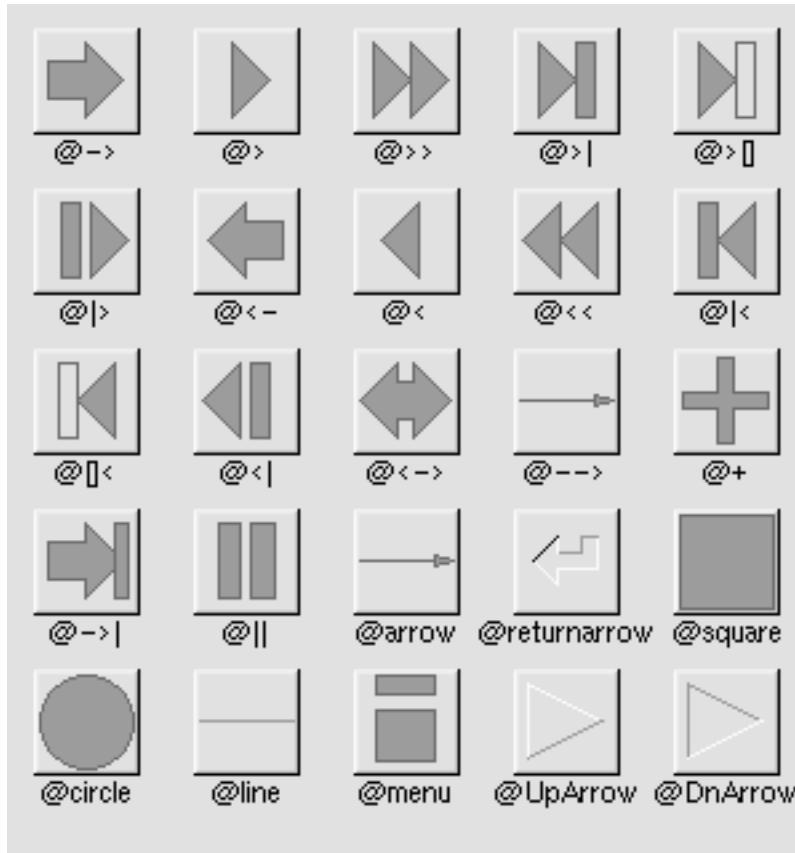

## Initialization

*itype* -- an integer number that modify the appearance of the target widget.

The legal values of *itype* are:

- 0 - normal label
- 1 - no label (hides the text)
- 2 - symbol label (see below)
- 3 - shadow label
- 4 - engraved label
- 5- embossed label
- 6- bitmap label (not implemented yet)
- 7- pixmap label (not implemented yet)
- 8- image label (not implemented yet)
- 9- multi label (not implemented yet)
- 10- free-type label (not implemented yet)

When using *itype*=3 (symbol label), it is possible to assign a graphical symbol instead of the text label of the target widget. In this case, the string of the target label must always start with “@”. If it starts with something else (or the symbol is not found), the label is drawn normally. The following symbols are supported:

FLTK label supported symbols.

The @ sign may be followed by the following optional “formatting” characters, in this order:

1. “#” forces square scaling rather than distortion to the widget's shape.
2. +[1-9] or -[1-9] tweaks the scaling a little bigger or smaller.
3. [1-9] rotates by a multiple of 45 degrees. “6” does nothing, the others point in the direction of that key on a numeric keypad.

Notice that with *FLbox* and *FLbutton*, it is not necessary to call *FLsetTextType* opcode at all in order to use a symbol. In this case, it is sufficient to set a label starting with “@” followed by the proper formatting string.

*ihandle* -- an integer number (used as unique identifier) taken from the output of a previously located widget opcode (which corresponds to the target widget). It is used to unequivocally identify the widget when modifying its appearance with this class of opcodes. The user must not set the *ihandle* value directly, otherwise a Csound crash will occur.

## See Also

# FLsetVal\_i

FLsetVal\_i — Sets the value of a FLTK valuator to a number provided by the user.

## Description

*FLsetVal\_i* forces the value of a valuator to a number provided by the user.

## Syntax

```
FLsetVal_i ivalue, ihandle
```

## Initialization

*ihandle* -- an integer number (used as unique identifier) taken from the output of a previously located widget opcode (which corresponds to the target widget). It is used to unequivocally identify the widget when modifying its appearance with this class of opcodes. The user must not set the *ihandle* value directly, otherwise a Csound crash will occur.

## Performance

*ivalue* -- Value to set the widget to.

### Note

*FLsetVal* is not fully implemented yet, and may crash in certain cases (e.g. when setting the value of a widget connected to a *FLvalue* widget- in this case use two separate *FLsetVal\_i*).

## See Also

*FLcolor2, FLhide, FLlabel, FLsetAlign, FLsetBox, FLsetColor, FLsetColor2, FLsetFont, FLsetPosition, FLsetSize, FLsetText, FLsetTextColor, FLsetTextSize, FLsetTextType, FLsetVal\_i, FLsetVal, FLshow*

New in version 4.22

# FLsetVal

**FLsetVal** — Sets the value of a FLTK valuator at control-rate.

## Description

*FLsetVal* is almost identical to *FLsetVal\_i*. Except it operates at k-rate and it affects the target valuator only when *ktrig* is set to a non-zero value.

## Syntax

```
FLsetVal ktrig, kvalue, ihandle
```

## Initialization

*ihandle* -- an integer number (used as unique identifier) taken from the output of a previously located widget opcode (which corresponds to the target widget). It is used to unequivocally identify the widget when modifying its appearance with this class of opcodes. The user must not set the *ihandle* value directly, otherwise a Csound crash will occur.

## Performance

*ktrig* -- triggers the opcode when different than 0.

*kvalue* -- Value to set the widget to.

### Note

*FLsetVal* is not fully implemented yet, and may crash in certain cases (e.g. when setting the value of a widget connected to a *FLvalue* widget- in this case use two separate *FLsetVal*)

## See Also

New in version 4.22

# FLshow

**FLshow** — Restores the visibility of a previously hidden FLTK widget.

## Description

*FLshow* restores the visibility of a previously hidden widget.

## Syntax

```
FLshow ihandle
```

## Initialization

*ihandle* -- an integer number (used as unique identifier) taken from the output of a previously located widget opcode (which corresponds to the target widget). It is used to unequivocally identify the widget when modifying its appearance with this class of opcodes. The user must not set the *ihandle* value directly, otherwise a Csound crash will occur.

## See Also

# FLslidBnk

FLslidBnk — A FLTK widget containing a bank of horizontal sliders.

## Description

*FLslidBnk* is a widget containing a bank of horizontal sliders.

## Syntax

```
FLslidBnk "names", inumsliders [, ioutable] [, iwidth] [, iheight] [, ix] \
[, iy] [, itypetable] [, iexptable] [, istart_index] [, iminmaxtable]
```

## Initialization

*"names"* -- a double-quoted string containing the names of each slider. Each slider can have a different name. Separate each name with "@" character, for example: "frequency@amplitude@cutoff". It is possible to not provide any name by giving a single space ". In this case, the opcode will automatically assign a progressive number as a label for each slider.

*inumsliders* -- the number of sliders.

*ioutable* (optional, default=0) -- number of a previously-allocated table in which to store output values of each slider. The user must be sure that table size is large enough to contain all output cells, otherwise a segfault will crash Csound. By assigning zero to this argument, the output will be directed to the zak space in the k-rate zone. In this case, the zak space must be previously allocated with the *zakinit* opcode and the user must be sure that the allocation size is big enough to cover all sliders. The default value is zero (i.e. store output in zak space).

*istart\_index* (optional, default=0) -- an integer number referring to a starting offset of output cell locations. It can be positive to allow multiple banks of sliders to output in the same table or in the zak space. The default value is zero (no offset).

*iminmaxtable* (optional, default=0) -- number of a previously-defined table containing a list of min-max pairs, referred to each slider. A zero value defaults to the 0 to 1 range for all sliders without necessity to provide a table. The default value is zero.

*iexptable* (optional, default=0) -- number of a previously-defined table containing a list of identifiers (i.e. integer numbers) provided to modify the behaviour of each slider independently. Identifiers can assume the following values:

- -1 -- exponential curve response
- 0 -- linear response
- number > than 0 -- follow the curve of a previously-defined table to shape the response of the corresponding slider. In this case, the number corresponds to table number.

You can assume that all sliders of the bank have the same response curve (exponential or linear). In this case, you can assign -1 or 0 to *iexptable* without worrying about previously defining any table. The default value is zero (all sliders have a linear response, without having to provide a table).

*itypetable* (optional, default=0) -- number of a previously-defined table containing a list of identifiers

(i.e. integer numbers) provided to modify the aspect of each individual slider independently. Identifiers can assume the following values:

- 0 = Nice slider
- 1 = Fill slider
- 3 = Normal slider
- 5 = Nice slider
- 7 = Nice slider with down-box

You can assume that all sliders of the bank have the same aspect. In this case, you can assign a negative number to *itypetable* without worrying about previously defining any table. Negative numbers have the same meaning of the corresponding positive identifiers with the difference that the same aspect is assigned to all sliders. You can also assign a random aspect to each slider by setting *itypetable* to a negative number lower than -7. The default value is zero (all sliders have the aspect of nice sliders, without having to provide a table).

You can add 20 to a value inside the table to make the slider "plastic", or subtract 20 if you want to set the value for all widgets without defining a table (e.g. -21 to set all sliders types to Plastic Fill slider).

*iwidth* (optional) -- width of the rectangular area containing all sliders of the bank, excluding text labels, that are placed to the left of that area.

*iheight* (optional) -- height of the rectangular area containing all sliders of the bank, excluding text labels, that are placed to the left of that area.

*ix* (optional) -- horizontal position of the upper left corner of the rectangular area containing all sliders belonging to the bank. You have to leave enough space, at the left of that rectangle, in order to make sure labels of sliders to be visible. This is because the labels themselves are external to the rectangular area.

*iy* (optional) -- vertical position of the upper left corner of the rectangular area containing all sliders belonging to the bank. You have to leave enough space, at the left of that rectangle, in order to make sure labels of sliders to be visible. This is because the labels themselves are external to the rectangular area.

## Performance

There are no k-rate arguments, even if cells of the output table (or the zak space) are updated at k-rate.

*FLslidBnk* is a widget containing a bank of horizontal sliders. Any number of sliders can be placed into the bank (*inumsliders* argument). The output of all sliders is stored into a previously allocated table or into the zak space (*ioutable* argument). It is possible to determine the first location of the table (or of the zak space) in which to store the output of the first slider by means of *istart\_index* argument.

Each slider can have an individual label that is placed to the left of it. Labels are defined by the "*names*" argument. The output range of each slider can be individually set by means of an external table (*iminmaxtable* argument). The curve response of each slider can be set individually, by means of a list of identifiers placed in a table (*iexptable* argument). It is possible to define the aspect of each slider independently or to make all sliders have the same aspect (*itypetable* argument).

The *iwidth*, *iheight*, *ix*, and *iy* arguments determine width, height, horizontal and vertical position of the rectangular area containing sliders. Notice that the label of each slider is placed to the left of them and is not included in the rectangular area containing sliders. So the user should leave enough space to the left of the bank by assigning a proper *ix* value in order to leave labels visible.

## IMPORTANT!

Notice that the tables used by *FLslidBnk* must be created with the *ftgen* opcode and placed in the orchestra before the corresponding valuator. They can not be placed in the score. This is because tables placed in the score are created later than the initialization of the opcodes placed in the header section of the orchestra.

## Examples

Here is an example of the *FLslidBnk* opcode. It uses the file *FLslidBnk.csd* [examples/FLslidBnk.csd].

### Example 284. Example of the **FLslidBnk** opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# FLslidBnk2

FLslidBnk2 — A FLTK widget containing a bank of horizontal sliders.

## Description

*FLslidBnk2* is a widget containing a bank of horizontal sliders.

## Syntax

```
FLslidBnk2 "names", inumsliders, ioutable, iconfigtable [,iwidth, iheight, ix, iy, istart_index]
```

## Initialization

“names” -- a double-quoted string containing the names of each slider. Each slider can have a different name. Separate each name with “@” character, for example: “frequency@amplitude@cutoff”. It is possible to not provide any name by giving a single space “ ”. In this case, the opcode will automatically assign a progressive number as a label for each slider.

*inumsliders* -- the number of sliders.

*ioutable* (optional, default=0) -- number of a previously-allocated table in which to store output values of each slider. The user must be sure that table size is large enough to contain all output cells, otherwise a segfault will crash Csound. By assigning zero to this argument, the output will be directed to the zak space in the k-rate zone. In this case, the zak space must be previously allocated with the *zakinit* opcode and the user must be sure that the allocation size is big enough to cover all sliders. The default value is zero (i.e. store output in zak space).

*iconfigtable* -- in the *FLslidBnk2* and *FLvslidBnk2* opcodes, this table replaces *iminmaxtable*, *iexptable* and *istyletable*, all these parameters being placed into a single table. This table has to be filled with a group of 4 parameters for each slider in this way:

min1, max1, exp1, style1, min2, max2, exp2, style2, min3, max3, exp3, style3 etc.

for example using GEN02 you can type:

```
inum ftgen 1,0,256, -2, 0,1,0,1, 100, 5000, -1, 3, 50, 200, -1, 5,..... [etcetera]
```

In this example the first slider will be affected by the [0,1,0,1] parameters (the range will be 0 to 1, it will have linear response, and its aspect will be a fill slider), the second slider will be affected by the [100,5000,-1,3] parameters (the range is 100 to 5000, the response is exponential and the aspect is a normal slider), the third slider will be affected by the [50,200,-1,5] parameters (the range is 50 to 200, the behavior exponential, and the aspect is a nice slider), and so on.

*iwidth* (optional) -- width of the rectangular area containing all sliders of the bank, excluding text labels, that are placed to the left of that area.

*iheight* (optional) -- height of the rectangular area containing all sliders of the bank, excluding text labels, that are placed to the left of that area.

*ix* (optional) -- horizontal position of the upper left corner of the rectangular area containing all sliders belonging to the bank. You have to leave enough space, at the left of that rectangle, in order to make

sure labels of sliders to be visible. This is because the labels themselves are external to the rectangular area.

*iy* (optional) -- vertical position of the upper left corner of the rectangular area containing all sliders belonging to the bank. You have to leave enough space, at the left of that rectangle, in order to make sure labels of sliders to be visible. This is because the labels themselves are external to the rectangular area.

*istart\_index* (optional, default=0) -- an integer number referring to a starting offset of output cell locations. It can be positive to allow multiple banks of sliders to output in the same table or in the zak space. The default value is zero (no offset).

## Performance

There are no k-rate arguments, even if cells of the output table (or the zak space) are updated at k-rate.

*FLslidBnk2* is a widget containing a bank of horizontal sliders. Any number of sliders can be placed into the bank (*inumsliders* argument). The output of all sliders is stored into a previously allocated table or into the zak space (*ioutable* argument). It is possible to determine the first location of the table (or of the zak space) in which to store the output of the first slider by means of *istart\_index* argument.

Each slider can have an individual label that is placed to the left of it. Labels are defined by the “*names*” argument. The output range of each slider can be individually set by means of the *min* and *max* values inside the *iconfigtable* table. The curve response of each slider can be set individually, by means of a list of identifiers placed in the *iconfigtable* table (*exp* argument). It is possible to define the aspect of each slider independently or to make all sliders have the same aspect (*style* argument in the *iconfigtable* table).

The *iwidth*, *iheight*, *ix*, and *iy* arguments determine width, height, horizontal and vertical position of the rectangular area containing sliders. Notice that the label of each slider is placed to the left of them and is not included in the rectangular area containing sliders. So the user should leave enough space to the left of the bank by assigning a proper *ix* value in order to leave labels visible.

### IMPORTANT!

Notice that the tables used by *FLslidBnk2* must be created with the *fgen* opcode and placed in the orchestra before the corresponding valuator. They can not be placed in the score. This is because tables placed in the score are created later than the initialization of the opcodes placed in the header section of the orchestra.

## Examples

Here is an example of the *FLslidBnk2* opcode. It uses the file *FLslidBnk2.csd* [examples/*FLslidBnk2.csd*].

### Example 285. Example of the **FLslidBnk2** opcode.

# FLslidBnkGetHandle

`FLslidBnkGetHandle` — gets the handle of last slider bank created.

## Description

*FLslidBnkGetHandle* gets the handle of last slider bank created.

## Syntax

```
ihandle FLslidBnkGetHandle
```

## Initialization

*ihandle* - handle of the sliderBnk (to be used to set its values).

## Performance

There are no k-rate arguments, even if cells of the output table (or the zak space) are updated at k-rate.

*FLslidBnkGetHandle* gets the handle of last slider bank created. This opcode must follow corresponding *FLslidBnk* (or *FLvslidBnk*, *FLslidBnk2* and *FLvslidBnk2*) immediately, in order to get its handle.

See the entry for *FLslidBnk2Setk* to see an example of usage.

# FLslidBnkSet

FLslidBnkSet — modify the values of a slider bank.

## Description

*FLslidBnkSet* modifies the values of a slider bank according to an array of values stored in a table.

## Syntax

```
FLslidBnkSet ihandle, ifn [, istartIndex, istartSlid, inumSlid]
```

## Initialization

*ihandle* - handle of the sliderBnk (to be used to set its values).

*ifn* - number of a table containing an array of values to set each slider to.

*istartIndex* - (optional) starting index of the table element of to be evaluated firstly. Default value is zero

*istartSlid* - (optional) starting slider to be evaluated. Default 0, denoting the first slider.

*inumSlid* - (optional) number of sliders to be updated. Default 0, denoting all sliders.

## Performance

*FLslidBnkSet* modifies the values of a slider bank (created with *FLslidBnk* or with *FLvslidBnk*) according to an array of values stored into table *ifn*. It actually allows to update an *FLslidBnk* (or *FLvslidBnk*) bank of sliders (for instance, using the *slider8table* opcode) to a set of values located in a table. User has to set *ihandle* argument to the handle got from *FLslidBnkGetHandle* opcode. It works at init-rate only. It is possible to reset only a range of sliders, by using the optional arguments *istartIndex*, *istartSlid*, *inumSlid*

There is a k-rate version of this opcode called *FLslidBnkSetk*.

# FLslidBnkSetk

**FLslidBnkSetk** — modify the values of a slider bank.

## Description

*FLslidBnkSetk* modifies the values of a slider bank according to an array of values stored in a table.

## Syntax

```
FLslidBnkSetk ktrig, ihandle, ifn [, istartIndex, istartSlid, inumSlid]
```

## Initialization

*ihandle* - handle of the sliderBnk (to be used to set its values).

*ifn* - number of a table containing an array of values to set each slider to.

*istartIndex* - (optional) starting index of the table element of to be evaluated firstly. Default value is zero

*istartSlid* - (optional) starting slider to be evaluated. Default 0, denoting the first slider.

*inumSlid* - (optional) number of sliders to be updated. Default 0, denoting all sliders.

## Performance

*ktrig* – the output of *FLslidBnkSetk* consists of a trigger that informs if sliders have to be updated or not. A non-zero value forces the slider to be updated.

*FLslidBnkSetk* is similar to *FLslidBnkSet* but allows k-rate to modify the values of *FLslidBnk* (*FLslidBnkSetk* can also be used with *FLvslidBnk*, obtaining identical result). It also allows the slider bank to be joined with MIDI. If you are using MIDI (for instance, when using the *slider8table* opcode), *FLslidBnkSetk* changes the values of *FLslidBnk* bank of sliders to a set of values located in a table. This opcode is actually able to serve as a MIDI bridge to the *FLslidBnk* widget when used together with the *sliderXXtable* set of opcodes (see *slider8table* entry for more information). Notice, that, when you want to use table indexing as a curve response, it is not possible to do it directly in the *iconfigtable* configuration of *FLslidBnk2*, when you intend to use the *FLslidBnkSetk* opcode. In fact, corresponding *inputTable* element of *FLslidBnkSetk* must be set in linear mode and respect the 0 to 1 range. Even the corresponding elements of *sliderXXtable* must be set in linear mode and in the normalized range. You can do table indexing later, by using the *tab* and *tb* opcodes, and rescaling output according to max and min values. By the other hand, it is possible to use linear and exponential curve response directly, by setting the actual min-max range and flag both in the *iconfigtable* of corresponding *FLslidBnk2* and in *sliderXXtable*.

*FLslidBnkSetk* the k-rate version of *FLslidBnk2Set*.

# FLslidBnk2Set

**FLslidBnk2Set** — modify the values of a slider bank.

## Description

*FLslidBnk2Set* modifies the values of a slider bank according to an array of values stored in a table.

## Syntax

```
FLslidBnk2Set ihandle, ifn [, istartIndex, istartSlid, inumSlid]
```

## Initialization

*ihandle* - handle of the sliderBnk (to be used to set its values).

*ifn* - number of a table containing an array of values to set each slider to.

*istartIndex* - (optional) starting index of the table element of to be evaluated firstly. Default value is zero

*istartSlid* - (optional) starting slider to be evaluated. Default 0, denoting the first slider.

*inumSlid* - (optional) number of sliders to be updated. Default 0, denoting all sliders.

## Performance

*FLslidBnk2Set* modifies the values of a slider bank (created with *FLslidBnk2* or with *FLvslidBnk2*) according to an array of values stored into table *ifn*. It actually allows to update an *FLslidBnk2* (or *FLvslidBnk2*) bank of sliders (for instance, using the *slider8table* opcode) to a set of values located in a table. User has to set *ihandle* argument to the handle got from *FLslidBnkGetHandle* opcode. It works at init-rate only. It is possible to reset only a range of sliders, by using the optional arguments *istartIndex*, *istartSlid*, *inumSlid*

*FLslidBnk2Set* is identical to *FLslidBnkSet*, but works on *FLslidBnk2* and *FLvslidBnk2* instead of *FLslidBnk* and *FLvslidBnk*.

There is a k-rate version of this opcode called *FLslidBnk2Setk*.

# FLslider

**FLslider** — Puts a slider into the corresponding FLTK container.

## Description

*FLslider* puts a slider into the corresponding container.

## Syntax

```
kout, ihandle FLslider "label", imin, imax, iexp, itype, idisp, iwidth, \
iheight, ix, iy
```

## Initialization

*ihandle* -- a handle value (an integer number) that unequivocally references a corresponding widget. This is used by other opcodes that modify a widget's properties (see *Modifying FLTK Widget Appearance*). It is automatically output by *FLslider* and must not be set by the user label. (The user label is a double-quoted string containing some user-provided text placed near the widget.)

*"label"* -- a double-quoted string containing some user-provided text, placed near the corresponding widget.

*imin* -- minimum value of output range (corresponds to the left value for horizontal sliders, and the top value for vertical sliders).

*imax* -- maximum value of output range (corresponds to the right value for horizontal sliders, and the bottom value for vertical sliders).

The *imin* argument may be greater than *imax* argument. This has the effect of “reversing” the object so the larger values are in the opposite direction. This also switches which end of the filled sliders is filled.

*iexp* -- an integer number denoting the behaviour of valuator:

- 0 = valuator output is linear
- -1 = valuator output is exponential

All other positive numbers for *iexp* indicate the number of an existing table that is used for indexing. Linear interpolation is provided in table indexing. A negative table number suppresses interpolation.

### IMPORTANT!

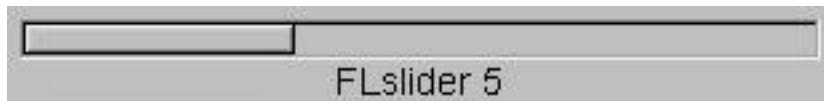

Notice that the tables used by valuators must be created with the *ftgen* opcode and placed in the orchestra before the corresponding valuator. They can not be placed in the score. This is because tables placed in the score are created later than the initialization of the opcodes placed in the header section of the orchestra.

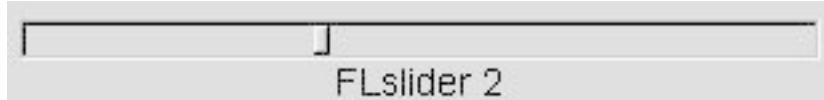

*itype* -- an integer number denoting the appearance of the valuator.

The *itype* argument can be set to the following values:

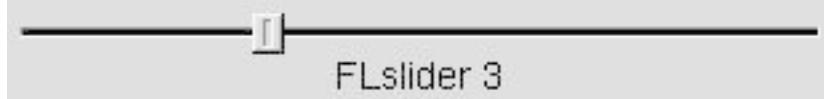

- 1 - shows a horizontal fill slider
- 2 - a vertical fill slider
- 3 - a horizontal engraved slider
- 4 - a vertical engraved slider
- 5 - a horizontal nice slider
- 6 - a vertical nice slider
- 7 - a horizontal up-box nice slider
- 8 - a vertical up-box nice slider

FLslider - a horizontal fill slider (itype=1).

FLslider - a horizontal engraved slider (itype=3).

FLslider - a horizontal nice slider (itype=5).

You can also create "plastic" looking sliders by adding 20 to *itype*.

*idisp* -- a handle value that was output from a previous instance of the *FLvalue* opcode to display the current value of the current valuator in the *FLvalue* widget itself. If the user doesn't want to use this feature that displays current values, it must be set to a negative number by the user.

*iwidth* -- width of widget.

*iheight* -- height of widget.

*ix* -- horizontal position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*iy* -- vertical position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

## Performance

*kout* -- output value

FLsliders are created with the minimum value by default in the left/at the top. If you want to reverse the slider, reverse the values. See the example below.

## Examples

Here is an example of the FLslider opcode. It uses the file *FLslider.csd* [examples/FLslider.csd].

### Example 287. Example of the FLslider opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>

February 2004. Thanks to a note from Dave Phillips, deleted the extraneous istep parameter.

Example written by Iain McCurdy, edited by Kevin Conder.

# FLtabs

**FLtabs** — Creates a tabbed FLTK interface.

## Description

*FLtabs* is a “file card tabs” interface that is useful to display several areas containing widgets in the same windows, alternatively. It must be used together with *FLgroup*, another container that groups child widgets.

## Syntax

```
FLtabs iwidth, iheight, ix, iy
```

## Initialization

*iwidth* -- width of widget.

*iheight* -- height of widget.

*ix* -- horizontal position of upper left corner of the valuator, relative to the upper left corner of corresponding window. Expressed in pixels.

*iy* -- vertical position of upper left corner of the valuator, relative to the upper left corner of corresponding window. Expressed in pixels.

## Performance

Containers are useful to format the graphic appearance of the widgets. The most important container is *FLpanel*, that actually creates a window. It can be filled with other containers and/or valiators or other kinds of widgets.

There are no k-rate arguments in containers.

*FLtabs* is a “file card tabs” interface that is useful to display several alternate areas containing widgets in the same window.

FLtabs.

It must be used together with *FLgroup*, another FLTK container opcode that groups child widgets.

## Examples

The following example code:

```

FLpanel "Panel1", 450, 550, 100, 100
FLscroll 450, 550, 0, 0
FLtabs 400, 550, 5, 5

FLgroup "sliders", 380, 500, 10, 40, 1
gk1, ihs FLslider "FLslider 1", 500, 1000, 2, 1, -1, 300, 15, 20, 50

# FLtext

FLtext — A FLTK widget opcode that creates a textbox.

## Description

*FLtext* allows the user to modify a parameter value by directly typing it into a text field.

## Syntax

```
kout, ihandle FLtext "label", imin, imax, istep, itype, iwidth, \
iheight, ix, iy
```

## Initialization

*ihandle* -- a handle value (an integer number) that unequivocally references a corresponding widget. This is used by other opcodes that modify a widget's properties (see *Modifying FLTK Widget Appearance*). It is automatically output by *FLtext* and must not be set by the user label. (The user label is a double-quoted string containing some user-provided text placed near the widget.)

“*label*” -- a double-quoted string containing some user-provided text, placed near corresponding widget.

*imin* -- minimum value of output range.

*imax* -- maximum value of output range.

*istep* -- a floating-point number indicating the increment of valuator value corresponding to the mouse dragging. The *istep* argument allows the user to arbitrarily slow mouse motion, enabling arbitrary precision.

*itype* -- an integer number denoting the appearance of the valuator.

The *itype* argument can be set to the following values:

- 1 - normal behaviour
- 2 - dragging operation is suppressed, instead it will appear two arrow buttons. A mouse-click on one of these buttons can increase/decrease the output value.
- 3 - text editing is suppressed, only mouse dragging modifies the output value.

*iwidth* -- width of widget.

*iheight* -- height of widget.

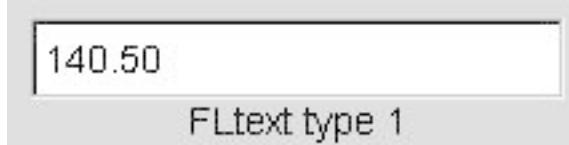

*ix* -- horizontal position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*-- vertical position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).*

## Performance

*kout* -- output value

*FLtext* allows the user to modify a parameter value by directly typing it into a text field:

FLtext.

Its value can also be modified by clicking on it and dragging the mouse horizontally. The *istep* argument allows the user to arbitrarily set the response on mouse dragging.

## Examples

Here is an example of the *FLtext* opcode. It uses the file *FLtext.csd* [examples/FLtext.csd].

### Example 290. Example of the **FLtext** opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# FLupdate

FLupdate — Same as the FLrun opcode.

## Description

Same as the *FLrun* opcode.

## Syntax

**FLupdate**

# fluidAllOut

fluidAllOut — Collects all audio from all Fluidsynth engines in a performance

## Syntax

```
aleft, aright fluidAllOut
```

## Description

Collects all audio from all Fluidsynth engines in a performance

## Performance

*aleft* -- Left channel audio output.

*aright* -- Right channel audio output.

Invoke fluidAllOut in an instrument definition numbered higher than any fluidcontrol instrument definitions. All SoundFonts send their audio output to this one opcode. Send a note with an indefinite duration to this instrument to turn the SoundFonts on for as long as required.

In this implementation, SoundFont effects such as chorus or reverb are used if and only if they are defaults for the preset. There is no means of turning such effects on or off, or of changing their parameters, from Csound.

## Examples

Here is an example of the fluidAllOut opcodes. It uses the file *fluidAllOut.csd* [examples/fluidAllOut.csd].

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac -+rtmidi=virtual -M0    ;;;realtime audio out and realtime midi in
;-iadc   ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime ouput leave only the line below:
;-o fluidAllOut.wav -W ;;; for file output any platform
</CsOptions>

# fluidCCi

fluidCCi — Sends a MIDI controller data message to fluid.

## Syntax

```
fluidccci iEngineNumber, iChannelNumber, iControllerNumber, iValue
```

## Description

Sends a MIDI controller data (MIDI controller number and value to use) message to a fluid engine by number on the user specified MIDI channel number.

## Initialization

*iEngineNumber* -- engine number assigned from fluidEngine

*iChannelNumber* -- MIDI channel number to which the Fluidsynth program is assigned: from 0 to 255. MIDI channels numbered 16 or higher are virtual channels.

*iControllerNumber* -- MIDI controller number to use for this message

*iValue* -- value to set for controller (usually 0-127)

## Performance

This opcode is useful for setting controller values at init time. For continuous changes, use fluidCCk.

## Examples

Here is an example of the fluidCCi opcodes. It uses the file *fluidCCi.csd* [examples/fluidCCi.csd].

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform

# fluidControl

fluidControl — Sends MIDI note on, note off, and other messages to a SoundFont preset.

## Syntax

```
fluidControl iengineenum, kstatus, kchannel, kdata1, kdata2
```

## Description

The fluid opcodes provide a simple Csound opcode wrapper around Peter Hanappe's Fluidsynth SoundFont2 synthesizer. This implementation accepts any MIDI note on, note off, controller, pitch bend, or program change message at k-rate. Maximum polyphony is 4096 simultaneously sounding voices. Any number of SoundFonts may be loaded and played simultaneously.

## Initialization

*iengineenum* -- engine number assigned from fluidEngine

## Performance

*kstatus* -- MIDI channel message status byte: 128 for note off, 144 for note on, 176 for control change, 192 for program change, or 224 for pitch bend.

*kchannel* -- MIDI channel number to which the Fluidsynth program is assigned: from 0 to 255. MIDI channels numbered 16 or higher are virtual channels.

*kdata1* -- For note on, MIDI key number: from 0 (lowest) to 127 (highest), where 60 is middle C. For continuous controller messages, controller number.

*kdata2* -- For note on, MIDI key velocity: from 0 (no sound) to 127 (loudest). For continuous controller messages, controller value.

Invoke fluidControl in instrument definitions that actually play notes and send control messages. Each instrument definition must consistently use one MIDI channel that was assigned to a Fluidsynth program using fluidLoad.

In this implementation, SoundFont effects such as chorus or reverb are used if and only if they are defaults for the preset. There is no means of turning such effects on or off, or of changing their parameters, from Csound.

## Examples

Here is a more complex example of the fluidsynth opcodes written by Istvan Varga. It uses the file *fluid-complex.csd* [examples/fluidcomplex.csd].

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Load external midi file from manual/examples
;-odac -T -F Anna.mid;;;realtime audio I/O and midifile in

# fluidEngine

fluidEngine — Instantiates a fluidsynth engine.

## Syntax

```
ienginenum fluidEngine [iReverbEnabled] [, iChorusEnabled] [,iNumChannels] [, iPolyphony]
```

## Description

Instantiates a fluidsynth engine, and returns *ienginenum* to identify the engine. *ienginenum* is passed to other other opcodes for loading and playing SoundFonts and gathering the generated sound.

## Initialization

*ienginenum* -- engine number assigned from fluidEngine.

*iReverbEnabled* -- optionally set to 0 to disable any reverb effect in the loaded SoundFonts.

*iChorusEnabled* -- optionally set to 0 to disable any chorus effect in the loaded SoundFonts.

*iNumChannels* -- number of channels to use; range is 16-256 and Csound default is 256 (Fluidsynth's default is 16).

*iPolyphony* -- number of voices to be played in parallel; range is 16-4096 and Csound default is 4096 (Fluidsynth's default is 256). Note: this is not the number of notes played at the same time as a single note may use create multiple voices depending on instrument zones and velocity/key of played note.

## Examples

Here is example of the fluidsynth opcodes using 2 engines. It uses the file *fluidEngine.csd* [examples/fluidEngine.csd] and *midichn\_advanced.mid* [examples/midichn\_advanced.mid].

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform

# fluidLoad

fluidLoad — Loads a SoundFont into a fluidEngine, optionally listing SoundFont contents.

## Syntax

```
isfnum fluidLoad soundfont, ienginenum[, ilistpresets]
```

## Description

Loads a SoundFont into an instance of a fluidEngine, optionally listing banks and presets for SoundFont.

## Initialization

*isfnum* -- number assigned to just-loaded soundfont.

*soundfont* -- string specifying a SoundFont filename. Note that any number of SoundFonts may be loaded (obviously, by different invocations of fluidLoad).

*ienginenum* -- engine number assigned from fluidEngine

*ilistpresets* -- optional, if specified, lists all Fluidsynth programs for the just-loaded SoundFont. A Fluidsynth program is a combination of SoundFont ID, bank number, and preset number that is assigned to a MIDI channel.

## Performance

Invoke fluidLoad in the orchestra header, any number of times. The same SoundFont may be invoked to assign programs to MIDI channels any number of times; the SoundFont is only loaded the first time.

## Examples

Here is an example of the fluidLoad opcode. It uses the file *fluidLoad.csd* [examples/fluidLoad.csd] and *07AcousticGuitar.sf2* [examples/07AcousticGuitar.sf2].

### Example 291. Example of the fluidLoad opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# fluidNote

fluidNote — Plays a note on a channel in a fluidSynth engine.

## Syntax

```
fluidNote ienginenum, ichannelnum, imidikey, imidivel
```

## Description

Plays a note at *imidikey* pitch and *imidivel* velocity on *ichannelnum* channel of number *ienginenum* fluidEngine.

## Initialization

*ienginenum* -- engine number assigned from fluidEngine

*ichannelnum* -- which channel number to play a note on in the given fluidEngine

*imidikey* -- MIDI key for note (0-127)

*imidivel* -- MIDI velocity for note (0-127)

## Examples

Here is an example of the fluidNote opcode. It uses the file *fluidNote.csd* [examples/fluidNote.csd] and *19Trumpet.sf2* [examples/19Trumpet.sf2].

### Example 292. Example of the fluidNote opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# fluidOut

fluidOut — Outputs sound from a given fluidEngine

## Syntax

```
aleft, aright fluidout ienginenum
```

## Description

Outputs the sound from a fluidEngine.

## Initialization

*ienginenum* -- engine number assigned from fluidEngine

## Performance

*aleft* -- Left channel audio output.

*aright* -- Right channel audio output.

Invoke fluidOut in an instrument definition numbered higher than any fluidcontrol instrument definitions. All SoundFonts used in the fluidEngine numbered *ienginenum* send their audio output to this one opcode. Send a note with an indefinite duration to this instrument to turn the SoundFonts on for as long as required.

## Examples

Here is an example of the fluidOut opcode with two fluidOuts. It uses the file *fluidOut.csd*, *01hpschd.sf2* [examples/01hpschd.sf2] and *22Bassoon.csd* [examples/22Bassoon.sf2].

### Example 293. Example of the fluidOut opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# fluidProgramSelect

fluidProgramSelect — Assigns a preset from a SoundFont to a channel on a fluidEngine.

## Syntax

```
fluidProgramSelect iengineenum, ichannelnum, isfnum, ibanknum, ipresetnum
```

## Description

Assigns a preset from a SoundFont to a channel on a fluidEngine.

## Initialization

*iengineenum* -- engine number assigned from fluidEngine

*ichannelnum* -- which channel number to use for the preset in the given fluidEngine

*isfnum* -- number of the SoundFont from which the preset is assigned

*ibanknum* -- number of the bank in the SoundFont from which the preset is assigned

*ipresetnum* -- number of the preset to assign

## Examples

Here is an example of the fluidProgramSelect opcode. It uses the file *fluidProgramSelect.csd* [examples/fluidProgramSelect.csd].

# fluidSetInterpMethod

fluidSetInterpMethod — Set interpolation method for channel in Fluid Engine

## Syntax

```
fluidSetInterpMethod ienginenum, ichannelnum, iInterpMethod
```

## Description

Set interpolation method for channel in Fluid Engine. Lower order interpolation methods will render faster at lower fidelity while higher order interpolation methods will render slower at higher fidelity. Default interpolation for a channel is 4th order interpolation.

## Initialization

*ienginenum* -- engine number assigned from fluidEngine

*ichannelnum* -- which channel number to use for the preset in the given fluidEngine

*iInterpMethod* -- interpolation method, can be any of the following

- 0 -- No Interpolation
- 1 -- Linear Interpolation
- 4 -- 4th Order Interpolation (Default)
- 7 -- 7th Order Interpolation (Highest)

## Examples

Here is an example of the fluidSetInterpMethod opcode. It uses the file *fluidSetInterpMethod.csd* [examples/fluidSetInterpMethod.csd] and *07AcousticGuitar.sf2* [examples/07AcousticGuitar.sf2].

### Example 294. Example of the fluidSetInterpMethod opcode.

# FLvalue

**FLvalue** — Shows the current value of a FLTK valuator.

## Description

*FLvalue* shows current the value of a valuator in a text field.

## Syntax

```
ihandle FLvalue "label", iwidth, iheight, ix, iy
```

## Initialization

*ihandle* -- handle value (an integer number) that unequivocally references the corresponding valuator. It can be used for the *idisp* argument of a valuator.

“*label*” -- a double-quoted string containing some user-provided text, placed near the corresponding widget.

*iwidth* -- width of widget.

*iheight* -- height of widget.

*ix* -- horizontal position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

*iy* -- vertical position of upper left corner of the valuator, relative to the upper left corner of corresponding window (expressed in pixels).

## Performance

*FLvalue* shows the current values of a valuator in a text field. It outputs *ihandle* that can then be used for the *idisp* argument of a valuator (see the *FLTK Valuators section*). In this way, the values of that valuator will be dynamically be shown in a text field.

### Note

Note that *FLvalue* is not a valuator and its value cannot be modified. The value for an *FLvalue* widget should be set only by other widgets, and NOT from *FLsetVal* or *FLsetVal\_i* since this can cause Csound to crash.

## Examples

Here is an example of the *FLvalue* opcode. It uses the file *FLvalue.csd* [examples/FLvalue.csd].

### Example 295. Example of the **FLvalue** opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command

line flags.

# FLvkeybd

**FLvkeybd** — An FLTK widget opcode that creates a virtual keyboard widget.

## Description

An FLTK widget opcode that creates a virtual keyboard widget. This must be used in conjunction with the virtual midi keyboard driver for this to operate correctly. The purpose of this opcode is for making demo versions of MIDI orchestras with the virtual keyboard embedded within the main window.

### Note

The widget version of the virtual keyboard does not include the MIDI sliders found in the full window version of the virtual keyboard.

## Syntax

```
FLvkeybd "keyboard.map", iwidth, iheight, ix, iy
```

## Initialization

*"keyboard.map"* -- a double-quoted string containing the keyboard map to use. An empty string ("") may be used to use the default bank/channel name values. See Virtual Midi Keyboard for more information on keyboard mappings.

*iwidth* -- width of widget.

*iheight* -- height of widget.

*ix* -- horizontal position of upper left corner of the keyboard, relative to the upper left corner of corresponding window (expressed in pixels).

*iy* -- vertical position of upper left corner of the keyboard, relative to the upper left corner of corresponding window (expressed in pixels).

### Note

The standard width and height for the virtual keyboard is 624x120 for the dialog version that is shown when FLvkeybd is not used.

# FLvslidBnk

FLvslidBnk — A FLTK widget containing a bank of vertical sliders.

## Description

*FLvslidBnk* is a widget containing a bank of vertical sliders.

## Syntax

```
FLvslidBnk "names", inumsliders [, ioutable] [, iwidth] [, iheight] [, ix] \
[, iy] [, itypetable] [, iexptable] [, istart_index] [, iminmaxtable]
```

## Initialization

*"names"* -- a double-quoted string containing the names of each slider. Each slider can have a different name. Separate each name with "@" character, for example: "frequency@amplitude@cutoff". It is possible to not provide any name by giving a single space ". In this case, the opcode will automatically assign a progressive number as a label for each slider.

*inumsliders* -- the number of sliders.

*ioutable* (optional, default=0) -- number of a previously-allocated table in which to store output values of each slider. The user must be sure that table size is large enough to contain all output cells, otherwise a segfault will crash Csound. By assigning zero to this argument, the output will be directed to the zak space in the k-rate zone. In this case, the zak space must be previously allocated with the *zakinit* opcode and the user must be sure that the allocation size is big enough to cover all sliders. The default value is zero (i.e. store output in zak space).

*istart\_index* (optional, default=0) -- an integer number referring to a starting offset of output cell locations. It can be positive to allow multiple banks of sliders to output in the same table or in the zak space. The default value is zero (no offset).

*iminmaxtable* (optional, default=0) -- number of a previously-defined table containing a list of min-max pairs, referred to each slider. A zero value defaults to the 0 to 1 range for all sliders without necessity to provide a table. The default value is zero.

*iexptable* (optional, default=0) -- number of a previously-defined table containing a list of identifiers (i.e. integer numbers) provided to modify the behaviour of each slider independently. Identifiers can assume the following values:

- -1 -- exponential curve response
- 0 -- linear response
- number > than 0 -- follow the curve of a previously-defined table to shape the response of the corresponding slider. In this case, the number corresponds to table number.

You can assume that all sliders of the bank have the same response curve (exponential or linear). In this case, you can assign -1 or 0 to *iexptable* without worrying about previously defining any table. The default value is zero (all sliders have a linear response, without having to provide a table).

*itypetable* (optional, default=0) -- number of a previously-defined table containing a list of identifiers

(i.e. integer numbers) provided to modify the aspect of each individual slider independently. Identifiers can assume the following values:

- 0 = Nice slider
- 1 = Fill slider
- 3 = Normal slider
- 5 = Nice slider
- 7 = Nice slider with down-box

You can assume that all sliders of the bank have the same aspect. In this case, you can assign a negative number to *itypetable* without worrying about previously defining any table. Negative numbers have the same meaning of the corresponding positive identifiers with the difference that the same aspect is assigned to all sliders. You can also assign a random aspect to each slider by setting *itypetable* to a negative number lower than -7. The default value is zero (all sliders have the aspect of nice sliders, without having to provide a table).

You can add 20 to a value inside the table to make the slider "plastic", or subtract 20 if you want to set the value for all widgets without defining a table (e.g. -21 to set all sliders types to Plastic Fill slider).

*iwidth* (optional) -- width of the rectangular area containing all sliders of the bank, excluding text labels, that are placed below that area.

*iheight* (optional) -- height of the rectangular area containing all sliders of the bank, excluding text labels, that are placed below that area.

*ix* (optional) -- horizontal position of the upper left corner of the rectangular area containing all sliders belonging to the bank. You have to leave enough space, below that rectangle, in order to make sure labels of sliders to be visible. This is because the labels themselves are external to the rectangular area.

*iy* (optional) -- vertical position of the upper left corner of the rectangular area containing all sliders belonging to the bank. You have to leave enough space, below that rectangle, in order to make sure labels of sliders to be visible. This is because the labels themselves are external to the rectangular area.

## Performance

There are no k-rate arguments, even if cells of the output table (or the zak space) are updated at k-rate.

*FLvslidBnk* is a widget containing a bank of vertical sliders. Any number of sliders can be placed into the bank (*inumsliders* argument). The output of all sliders is stored into a previously allocated table or into the zak space (*ioutable* argument). It is possible to determine the first location of the table (or of the zak space) in which to store the output of the first slider by means of *istart\_index* argument.

Each slider can have an individual label that is placed below it. Labels are defined by the "names" argument. The output range of each slider can be individually set by means of an external table (*iminmaxtable* argument). The curve response of each slider can be set individually, by means of a list of identifiers placed in a table (*iexptable* argument). It is possible to define the aspect of each slider independently or to make all sliders have the same aspect (*itypetable* argument).

The *iwidth*, *iheight*, *ix*, and *iy* arguments determine width, height, horizontal and vertical position of the rectangular area containing sliders. Notice that the label of each slider is placed below them and is not included in the rectangular area containing sliders. So the user should leave enough space below the bank by assigning a proper *iy* value in order to leave labels visible.

*FLvslidBnk* is identical to *FLslidBnk* except it contains vertical sliders instead of horizontal. Since the

width of each single slider is often small, it is recommended to leave only a single space in the names string (" "), in this case each slider will be automatically numbered.

## IMPORTANT!

Notice that the tables used by *FLvslidBnk* must be created with the *ftgen* opcode and placed in the orchestra before the corresponding valuator. They can not be placed in the score. This is because tables placed in the score are created later than the initialization of the opcodes placed in the header section of the orchestra.

# Examples

Here is an example of the *FLvslidBnk* opcode. It uses the file *FLvslidBnk.csd* [examples/FLvslidBnk.csd].

# FLvslidBnk2

FLvslidBnk2 — A FLTK widget containing a bank of vertical sliders.

## Description

*FLvslidBnk2* is a widget containing a bank of vertical sliders.

## Syntax

```
FLvslidBnk2 "names", inumsliders, ioutable, iconfigtable [,iwidth, iheight, ix, iy, istart_index]
```

## Initialization

“names” -- a double-quoted string containing the names of each slider. Each slider can have a different name. Separate each name with “@” character, for example: “frequency@amplitude@cutoff”. It is possible to not provide any name by giving a single space “ ”. In this case, the opcode will automatically assign a progressive number as a label for each slider.

*inumsliders* -- the number of sliders.

*ioutable* (optional, default=0) -- number of a previously-allocated table in which to store output values of each slider. The user must be sure that table size is large enough to contain all output cells, otherwise a segfault will crash Csound. By assigning zero to this argument, the output will be directed to the zak space in the k-rate zone. In this case, the zak space must be previously allocated with the *zakinit* opcode and the user must be sure that the allocation size is big enough to cover all sliders. The default value is zero (i.e. store output in zak space).

*iconfigtable* -- in the *FLslidBnk2* and *FLvslidBnk2* opcodes, this table replaces *iminmaxtable*, *iexptable* and *istyletable*, all these parameters being placed into a single table. This table has to be filled with a group of 4 parameters for each slider in this way:

min1, max1, exp1, style1, min2, max2, exp2, style2, min3, max3, exp3, style3 etc.

for example using GEN02 you can type:

```
inum ftgen 1,0,256, -2, 0,1,0,1, 100, 5000, -1, 3, 50, 200, -1, 5,..... [etcetera]
```

In this example the first slider will be affected by the [0,1,0,1] parameters (the range will be 0 to 1, it will have linear response, and its aspect will be a fill slider), the second slider will be affected by the [100,5000,-1,3] parameters (the range is 100 to 5000, the response is exponential and the aspect is a normal slider), the third slider will be affected by the [50,200,-1,5] parameters (the range is 50 to 200, the behavior exponential, and the aspect is a nice slider), and so on.

*iwidth* (optional) -- width of the rectangular area containing all sliders of the bank, excluding text labels, that are placed below that area.

*iheight* (optional) -- height of the rectangular area containing all sliders of the bank, excluding text labels, that are placed below that area.

*ix* (optional) -- horizontal position of the upper left corner of the rectangular area containing all sliders belonging to the bank. You have to leave enough space, below that rectangle, in order to make sure la-

bels of sliders to be visible. This is because the labels themselves are external to the rectangular area.

*iy* (optional) -- vertical position of the upper left corner of the rectangular area containing all sliders belonging to the bank. You have to leave enough space, below that rectangle, in order to make sure labels of sliders to be visible. This is because the labels themselves are external to the rectangular area.

*istart\_index* (optional, default=0) -- an integer number referring to a starting offset of output cell locations. It can be positive to allow multiple banks of sliders to output in the same table or in the zak space. The default value is zero (no offset).

## Performance

There are no k-rate arguments, even if cells of the output table (or the zak space) are updated at k-rate.

*FLvslidBnk2* is a widget containing a bank of vertical sliders. Any number of sliders can be placed into the bank (*inumsliders* argument). The output of all sliders is stored into a previously allocated table or into the zak space (*ioutable* argument). It is possible to determine the first location of the table (or of the zak space) in which to store the output of the first slider by means of *istart\_index* argument.

Each slider can have an individual label that is placed below it. Labels are defined by the “*names*” argument. The output range of each slider can be individually set by means of the *min* and *max* values inside the *iconfigtable* table. The curve response of each slider can be set individually, by means of a list of identifiers placed in the *iconfigtable* table (*exp* argument). It is possible to define the aspect of each slider independently or to make all sliders have the same aspect (*style* argument in the *iconfigtable* table).

The *iwidth*, *iheight*, *ix*, and *iy* arguments determine width, height, horizontal and vertical position of the rectangular area containing sliders. Notice that the label of each slider is placed below them and is not included in the rectangular area containing sliders. So the user should leave enough space below the bank by assigning a proper *iy* value in order to leave labels visible.

*FLvslidBnk2* is identical to *FLslidBnk2* except it contains vertical sliders instead of horizontal. Since the width of each single slider is often small, it is recommended to leave only a single space in the names string (“ “), in this case each slider will be automatically numbered.

### IMPORTANT!

Notice that the tables used by *FLvslidBnk2* must be created with the *ftgen* opcode and placed in the orchestra before the corresponding valuator. They can not be placed in the score. This is because tables placed in the score are created later than the initialization of the opcodes placed in the header section of the orchestra.

# FLxyin

FLxyin — Senses the mouse cursor position in a user-defined area inside an FLpanel.

## Description

Similar to *xyin*, sense the mouse cursor position in a user-defined area inside an FLpanel.

## Syntax

```
koutx, kouty, kinside  FLxyin ioutx_min, ioutx_max, iouty_min, iouty_max, \
    iwindx_min, iwindx_max, iwindy_min, iwindy_max [, iexpx, iexpv, ioutx, iouty]
```

## Initialization

*ioutx\_min, ioutx\_max* - the minimum and maximum limits of the interval to be output (X or horizontal axis).

*iouty\_min, iouty\_max* - the minimum and maximum limits of the interval to be output (Y or vertical axis).

*iwindx\_min, iwindx\_max* - the X coordinate of the horizontal edges of the sensible area, relative to the FLpanel ,in pixels.

*iwindy\_min, iwindy\_max* - the Y coordinates of the vertical edges of the sensible area, relative to the FLpanel, in pixels.

*iexpx, iexpv* - (optional) integer numbers denoting the behavior of the x or y output: 0 -> output is linear; -1 -> output is exponential; any other number indicates the number of an existing table that is used for indexing. With a positive value for table number, linear interpolation is provided in table indexing. A negative table number suppresses interpolation. Notice that in normal operations, the table should be normalized and unipolar (i.e. all table elements should be in the zero to one range). In this case all table elements will be rescaled according to imax and imin. Anyway, it is possible to use non-normalized tables (created with a negative table number, that can contain elements of any value), in order to access the actual values of table elements, without rescaling, by assigning 0 to iout\_min and 1 to iout\_max.

*ioutx, iouty* – (optional) initial output values.

## Performance

*koutx, kouty* - output values, scaled according to user choices.

*kinside* - a flag that informs if the mouse cursor falls out of the rectangle of the user-defined area. If it is out of the area, *kinside* is set to zero.

*FLxyin* senses the mouse cursor position in a user-defined area inside an *FLpanel*. When *FLxyin* is called, the position of the mouse within the chosen area is returned at k-rate. It is possible to define the sensible area, as well the minimum and maximum values corresponding to the minimum and maximum mouse positions. Mouse buttons don't need to be pressed to make *FLxyin* to operate. It is able to function correctly even if other widgets (present in the *FLpanel*) overlap the sensible area.

*FLxyin* unlike most other FLTK opcodes can't be used inside the header, since it is not a widget. It is just a definition of an area for mouse sensing within an FLTK panel.

## Examples

Here is an example of the FLxyin opcode. It uses the file *FLxyin.csd* [examples/FLxyin.csd].

### Example 297. Example of the FLxyin opcode.

# fmb3

fmb3 — Uses FM synthesis to create a Hammond B3 organ sound.

## Description

Uses FM synthesis to create a Hammond B3 organ sound. It comes from a family of FM sounds, all using 4 basic oscillators and various architectures, as used in the TX81Z synthesizer.

## Syntax

```
ares fmb3 kamp, kfreq, kc1, kc2, kvdepth, kvrate[, ifn1, ifn2, ifn3, \
ifn4, ivfn]
```

## Initialization

*fmb3* takes 5 tables for initialization. The first 4 are the basic inputs and the last is the low frequency oscillator (LFO) used for vibrato. The last table should usually be a sine wave. These all default to a sine wave table.

The initial waves should be:

- *ifn1* -- sine wave
- *ifn2* -- sine wave
- *ifn3* -- sine wave
- *ifn4* -- sine wave

## Performance

*kamp* -- Amplitude of note.

*kfreq* -- Frequency of note played.

*kc1, kc2* -- Controls for the synthesizer:

- *kc1* -- Total mod index
- *kc2* -- Crossfade of two modulators
- *Algorithm* -- 4

*kvdepth* -- Vibrator depth

*kvrate* -- Vibrator rate

## Examples

---

Here is an example of the fmb3 opcode. It uses the file *fmb3.csd* [examples/fmb3.csd].

### Example 299. Example of the fmb3 opcode.

# fmbell

fmbell — Uses FM synthesis to create a tubular bell sound.

## Description

Uses FM synthesis to create a tubular bell sound. It comes from a family of FM sounds, all using 4 basic oscillators and various architectures, as used in the TX81Z synthesizer.

## Syntax

```
ares fmbell kamp, kfreq, kc1, kc2, kvdepth, kvrate[, ifn1, ifn2, ifn3, \
ifn4, ivfn, isus]
```

## Initialization

All these opcodes take 5 tables for initialization. The first 4 are the basic inputs and the last is the low frequency oscillator (LFO) used for vibrato. These all default to a siewave table.

The initial waves should be:

- *ifn1* -- sine wave
- *ifn2* -- sine wave
- *ifn3* -- sine wave
- *ifn4* -- sine wave

The optional argument *isus* controls how long the sound lasts, or how quickly it decays. It defaults to 4.

## Performance

*kamp* -- Amplitude of note.

*kfreq* -- Frequency of note played.

*kc1, kc2* -- Controls for the synthesizer:

- *kc1* -- Mod index 1
- *kc2* -- Crossfade of two outputs
- *Algorithm* -- 5

*kvdepth* -- Vibrator depth

*kvrate* -- Vibrator rate

## Examples

Here is an example of the fmbell opcode. It uses the file *fmbell.csd* [examples/fmbell.csd].

### Example 300. Example of the fmbell opcode.

# fof

fof — Produces sinusoid bursts useful for formant and granular synthesis.

## Description

Audio output is a succession of sinusoid bursts initiated at frequency *xfund* with a spectral peak at *xform*. For *xfund* above 25 Hz these bursts produce a speech-like formant with spectral characteristics determined by the k-input parameters. For lower fundamentals this generator provides a special form of granular synthesis.

## Syntax

```
ares fof xamp, xfund, xform, koct, kband, kris, kdur, kdec, iolaps, \
ifna, ifnb, itotdur [, iphs] [, ifmode] [, iskip]
```

## Initialization

*iolaps* -- number of preallocated spaces needed to hold overlapping burst data. Overlaps are frequency dependent, and the space required depends on the maximum value of *xfund* \* *kdur*. Can be over-estimated at no computation cost. Uses less than 50 bytes of memory per *iolap*.

*ifna*, *ifnb* -- table numbers of two stored functions. The first is a sine table for sineburst synthesis (size of at least 4096 recommended). The second is a rise shape, used forwards and backwards to shape the sineburst rise and decay; this may be linear (*GEN07*) or perhaps a sigmoid (*GEN19*).

*itotdur* -- total time during which this *fof* will be active. Normally set to p3. No new sineburst is created if it cannot complete its *kdur* within the remaining *itotdur*.

*iphs* (optional, default=0) -- initial phase of the fundamental, expressed as a fraction of a cycle (0 to 1). The default value is 0.

*ifmode* (optional, default=0) -- formant frequency mode. If zero, each sineburst keeps the *xform* frequency it was launched with. If non-zero, each is influenced by *xform* continuously. The default value is 0.

*iskip* (optional, default=0) -- If non-zero, skip initialisation (allows legato use).

## Performance

*xamp* -- peak amplitude of each sineburst, observed at the true end of its rise pattern. The rise may exceed this value given a large bandwidth (say, Q < 10) and/or when the bursts are overlapping.

*xfund* -- the fundamental frequency (in Hertz) of the impulses that create new sinebursts.

*xform* -- the formant frequency, i.e. freq of the sinusoid burst induced by each *xfund* impulse. This frequency can be fixed for each burst or can vary continuously (see *ifmode*).

*koct* -- octaviation index, normally zero. If greater than zero, lowers the effective *xfund* frequency by attenuating odd-numbered sinebursts. Whole numbers are full octaves, fractions transitional.

*kband* -- the formant bandwidth (at -6dB), expressed in Hz. The bandwidth determines the rate of exponential decay throughout the sineburst, before the enveloping described below is applied.

*kris*, *kdur*, *kdec* -- rise, overall duration, and decay times (in seconds) of the sinusoid burst. These values apply an enveloped duration to each burst, in similar fashion to a Csound *linen* generator but with rise and decay shapes derived from the *ifnb* input. *kris* inversely determines the skirtwidth (at -40 dB) of the induced formant region. *kdur* affects the density of sineburst overlaps, and thus the speed of computation. Typical values for vocal imitation are .003,.02,.007.

Csound's *fof* generator is loosely based on Michael Clarke's C-coding of IRCAM's *CHANT* program (Xavier Rodet et al.). Each *fof* produces a single formant, and the output of four or more of these can be summed to produce a rich vocal imitation. *fof* synthesis is a special form of granular synthesis, and this implementation aids transformation between vocal imitation and granular textures. Computation speed depends on *kdur*, *xfund*, and the density of any overlaps.

## Examples

Here is an example of the *fof* opcode. It uses the file *fof.csd* [examples/fof.csd].

### Example 306. Example of the *fof* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

*fof2* — Produces sinusoid bursts including k-rate incremental indexing with each successive burst.

## Description

Audio output is a succession of sinusoid bursts initiated at frequency *xfund* with a spectral peak at *xform*. For *xfund* above 25 Hz these bursts produce a speech-like formant with spectral characteristics determined by the k-input parameters. For lower fundamentals this generator provides a special form of granular synthesis.

*fof2* implements k-rate incremental indexing into *ifna* function with each successive burst.

## Syntax

```
ares fof2 xamp, xfund, xform, koct, kband, kris, kdur, kdec, iolaps, \
      ifna, ifnb, itotdur, kphs, kgliiss [, iskip]
```

## Initialization

*iolaps* -- number of preallocated spaces needed to hold overlapping burst data. Overlaps are frequency dependent, and the space required depends on the maximum value of *xfund* \* *kdur*. Can be over-estimated at no computation cost. Uses less than 50 bytes of memory per *iolap*.

*ifna*, *ifnb* -- table numbers of two stored functions. The first is a sine table for sineburst synthesis (size of at least 4096 recommended). The second is a rise shape, used forwards and backwards to shape the sineburst rise and decay; this may be linear (*GEN07*) or perhaps a sigmoid (*GEN19*).

*itotdur* -- total time during which this *fof* will be active. Normally set to p3. No new sineburst is created if it cannot complete its *kdur* within the remaining *itotdur*.

*iskip* (optional, default=0) -- If non-zero, skip initialization (allows legato use).

## Performance

*xamp* -- peak amplitude of each sineburst, observed at the true end of its rise pattern. The rise may exceed this value given a large bandwidth (say, Q < 10) and/or when the bursts are overlapping.

*xfund* -- the fundamental frequency (in Hertz) of the impulses that create new sinebursts.

*xform* -- the formant frequency, i.e. freq of the sinusoid burst induced by each *xfund* impulse. This frequency can be fixed for each burst or can vary continuously (see *ifmode*).

*koct* -- octaviation index, normally zero. If greater than zero, lowers the effective *xfund* frequency by attenuating odd-numbered sinebursts. Whole numbers are full octaves, fractions transitional.

*kband* -- the formant bandwidth (at -6dB), expressed in Hz. The bandwidth determines the rate of exponential decay throughout the sineburst, before the enveloping described below is applied.

*kris*, *kdur*, *kdec* -- rise, overall duration, and decay times (in seconds) of the sinusoid burst. These values apply an enveloped duration to each burst, in similar fashion to a Csound *linen* generator but with rise and decay shapes derived from the *ifnb* input. *kris* inversely determines the skirtwidth (at -40 dB) of the induced formant region. *kdur* affects the density of sineburst overlaps, and thus the speed of computa-

tion. Typical values for vocal imitation are .003,.02,.007.

*kphs* -- allows k-rate indexing of function table *ifna* with each successive burst, making it suitable for time-warping applications. Values of *kphs* are normalized from 0 to 1, 1 being the end of the function table *ifna*.

*kgliss* -- sets the end pitch of each grain relative to the initial pitch, in octaves. Thus *kgliss* = 2 means that the grain ends two octaves above its initial pitch, while *kgliss* = -3/4 has the grain ending a major sixth below. Each 1/12 added to *kgliss* raises the ending frequency one half-step. If you want no glissando, set *kgliss* to 0.

Csound's *fof* generator is loosely based on Michael Clarke's C-coding of IRCAM's *CHANT* program (Xavier Rodet et al.). Each *fof* produces a single formant, and the output of four or more of these can be summed to produce a rich vocal imitation. *fof* synthesis is a special form of granular synthesis, and this implementation aids transformation between vocal imitation and granular textures. Computation speed depends on *kdur*, *xfund*, and the density of any overlaps.

## Note

The ending frequency of any grain is equal to *kform* \*  $(2^kgliss)$ , so setting *kgliss* too high may result in aliasing. For example, *kform* = 3000 and *kgliss* = 3 places the ending frequency over the Nyquist if *sr* = 44100. It is a good idea to scale *kgliss* accordingly.

## Examples

Here is an example of the *fof2* opcode. It uses the file *fof2.csd* [examples/fof2.csd].

### Example 307. Example of the *fof2* opcode.

# fofilter

fofilter — Formant filter.

## Description

Fofilter generates a stream of overlapping sinewave grains, when fed with a pulse train. Each grain is the impulse response of a combination of two BP filters. The grains are defined by their attack time (determining the skirtwidth of the formant region at -60dB) and decay time (-6dB bandwidth). Overlapping will occur when  $1/\text{freq} < \text{decay}$ , but, unlike FOF, there is no upper limit on the number of overlaps. The original idea for this opcode came from J McCartney's formlet class in SuperCollider, but this is possibly implemented differently(?).

## Syntax

```
asig fofilter ain, xcf, xris, xdec[, istor]
```

## Initialization

*istor* --initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*asig* -- input signal.

*xcf* -- filter centre frequency

*xris* -- impulse response attack time (secs).

*xdec* -- impulse response decay time (secs).

## Examples

Here is an example of the fofilter opcode. It uses the file *fofilter.csd* [examples/fofilter.csd].

### Example 309. Example of the fofilter opcode.

# fog

fog — Audio output is a succession of grains derived from data in a stored function table

## Description

Audio output is a succession of grains derived from data in a stored function table *ifna*. The local envelope of these grains and their timing is based on the model of *fof* synthesis and permits detailed control of the granular synthesis.

## Syntax

```
ares fog xamp, xdens, xtrans, aspd, koct, kband, kris, kdur, kdec, \
      iolaps, ifna, ifnb, itotdur [, iphs] [, itmode] [, iskip]
```

## Initialization

*iolaps* -- number of pre-located spaces needed to hold overlapping grain data. Overlaps are density dependent, and the space required depends on the maximum value of *xdens* \* *kdur*. Can be over-estimated at no computation cost. Uses less than 50 bytes of memory per *iolap*.

*ifna*, *ifnb* -- table numbers of two stored functions. The first is the data used for granulation, usually from a soundfile (*GEN01*). The second is a rise shape, used forwards and backwards to shape the grain rise and decay; this is normally a sigmoid (*GEN19*) but may be linear (*GEN05*).

*itotdur* -- total time during which this *fog* will be active. Normally set to p3. No new grain is created if it cannot complete its *kdur* within the remaining *itotdur*.

*iphs* (optional) -- initial phase of the fundamental, expressed as a fraction of a cycle (0 to 1). The default value is 0.

*itmode* (optional) -- transposition mode. If zero, each grain keeps the *xtrans* value it was launched with. If non-zero, each is influenced by *xtrans* continuously. The default value is 0.

*iskip* (optional, default=0) -- If non-zero, skip initialization (allows legato use).

## Performance

*xamp* -- amplitude factor. Amplitude is also dependent on the number of overlapping grains, the interaction of the rise shape (*ifnb*) and the exponential decay (*kband*), and the scaling of the grain waveform (*ifna*). The actual amplitude may therefore exceed *xamp*.

*xdens* -- density. The frequency of grains per second.

*xtrans* -- transposition factor. The rate at which data from the stored function table *ifna* is read within each grain. This has the effect of transposing the original material. A value of 1 produces the original pitch. Higher values transpose upwards, lower values downwards. Negative values result in the function table being read backwards.

*aspd* -- Starting index pointer. *aspd* is the normalized index (0 to 1) to table *ifna* that determines the movement of a pointer used as the starting point for reading data within each grain. (*xtrans* determines the rate at which data is read starting from this pointer.)

*koct* -- octaviation index. The operation of this parameter is identical to that in *fof*.

*kband*, *kris*, *kdur*, *kdec* -- grain envelope shape. These parameters determine the exponential decay (*kband*), and the rise (*kris*), overall duration (*kdur*) and decay (*kdec*) times of the grain envelope. Their operation is identical to that of the local envelope parameters in *fof*.

## Examples

# fold

`fold` — Adds artificial foldover to an audio signal.

## Description

Adds artificial foldover to an audio signal.

## Syntax

```
ares fold asig, kincr
```

## Performance

*asig* -- input signal

*kincr* -- amount of foldover expressed in multiple of sampling rate. Must be  $\geq 1$

*fold* is an opcode which creates artificial foldover. For example, when *kincr* is equal to 1 with *sr*=44100, no foldover is added. When *kincr* is set to 2, the foldover is equivalent to a downsampling to 22050, when it is set to 4, to 11025 etc. Fractional values of *kincr* are possible, allowing a continuous variation of foldover amount. This can be used for a wide range of special effects.

## Examples

Here is an example of the *fold* opcode. It uses the file *fold.csd* [examples/fold.csd].

### Example 311. Example of the **fold** opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# follow

follow — Envelope follower unit generator.

## Description

Envelope follower unit generator.

## Syntax

```
ares follow asig, idt
```

## Initialization

*idt* -- This is the period, in seconds, that the average amplitude of *asig* is reported. If the frequency of *asig* is low then *idt* must be large (more than half the period of *asig* )

## Performance

*asig* -- This is the signal from which to extract the envelope.

## Examples

Here is an example of the follow opcode. It uses the file *follow.csd* [examples/follow.csd], and *beats.wav* [examples/beats.wav].

### Example 312. Example of the follow opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# follow2

follow2 — Another controllable envelope extractor.

## Description

A controllable envelope extractor using the algorithm attributed to Jean-Marc Jot.

## Syntax

```
ares follow2 asig, katt, krel
```

## Performance

*asig* -- the input signal whose envelope is followed

*katt* -- the attack rate (60dB attack time in seconds)

*krel* -- the decay rate (60dB decay time in seconds)

The output tracks the amplitude envelope of the input signal. The rate at which the output grows to follow the signal is controlled by the *katt*, and the rate at which it decreases in response to a lower amplitude, is controlled by the *krel*. This gives a smoother envelope than *follow*.

## Examples

Here is an example of the follow2 opcode. It uses the file *follow2.csd* [examples/follow2.csd], and *beats.wav* [examples/beats.wav].

### Example 313. Example of the follow2 opcode.

# foscil

foscil — A basic frequency modulated oscillator.

## Description

A basic frequency modulated oscillator.

## Syntax

```
ares foscil xamp, kcps, xcar, xmod, kndx, ifn [, iphs]
```

## Initialization

*ifn* -- function table number. Requires a wrap-around guard point.

*iphs* (optional, default=0) -- initial phase of waveform in table *ifn*, expressed as a fraction of a cycle (0 to 1). A negative value will cause phase initialization to be skipped. The default value is 0.

## Performance

*xamp* -- the amplitude of the output signal.

*kcps* -- a common denominator, in cycles per second, for the carrier and modulating frequencies.

*xcar* -- a factor that, when multiplied by the *kcps* parameter, gives the carrier frequency.

*xmod* -- a factor that, when multiplied by the *kcps* parameter, gives the modulating frequency.

*kndx* -- the modulation index.

*foscil* is a composite unit that effectively banks two *oscil* opcodes in the familiar Chowning FM setup, wherein the audio-rate output of one generator is used to modulate the frequency input of another (the “carrier”). Effective carrier frequency =  $kcps * xcar$ , and modulating frequency =  $kcps * xmod$ . For integral values of *xcar* and *xmod*, the perceived fundamental will be the minimum positive value of  $kcps * (xcar - n * xmod)$ ,  $n = 0,1,2,\dots$  The input *kndx* is the index of modulation (usually time-varying and ranging 0 to 4 or so) which determines the spread of acoustic energy over the partial positions given by  $n = 0,1,2,\dots$ , etc. *ifn* should point to a stored sine wave. Previous to version 3.50, *xcar* and *xmod* could be k-rate only.

The actual formula used for this implementation of FM synthesis is  $xamp * \cos(2\# * t * kcps * xcar + kndx * \sin(2\# * t * kcps * xmod) - \#)$ , assuming that the table is a sine wave.

## Examples

Here is an example of the foscil opcode. It uses the file *foscil.csd* [examples/foscil.csd].

### Example 314. Example of the foscil opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# foscili

foscili — Basic frequency modulated oscillator with linear interpolation.

## Description

Basic frequency modulated oscillator with linear interpolation.

## Syntax

```
ares foscili xamp, kcps, xcar, xmod, kndx, ifn [, iphs]
```

## Initialization

*ifn* -- function table number. Requires a wrap-around guard point.

*iphs* (optional, default=0) -- initial phase of waveform in table *ifn*, expressed as a fraction of a cycle (0 to 1). A negative value will cause phase initialization to be skipped. The default value is 0.

## Performance

*xamp* -- the amplitude of the output signal.

*kcps* -- a common denominator, in cycles per second, for the carrier and modulating frequencies.

*xcar* -- a factor that, when multiplied by the *kcps* parameter, gives the carrier frequency.

*xmod* -- a factor that, when multiplied by the *kcps* parameter, gives the modulating frequency.

*kndx* -- the modulation index.

*foscili* differs from *foscil* in that the standard procedure of using a truncated phase as a sampling index is here replaced by a process that interpolates between two successive lookups. Interpolating generators will produce a noticeably cleaner output signal, but they may take as much as twice as long to run. Adequate accuracy can also be gained without the time cost of interpolation by using large stored function tables of 2K, 4K or 8K points if the space is available.

## Examples

Here is an example of the foscili opcode. It uses the file *foscili.csd* [examples/foscili.csd].

### Example 315. Example of the foscili opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# fout

`fout` — Outputs a-rate signals to an arbitrary number of channels.

## Description

`fout` outputs  $N$  a-rate signals to a specified file of  $N$  channels.

## Syntax

```
fout ifilename, iformat, aout1 [, aout2, aout3,...,aoutN]  
fout ifilename, iformat, array[]
```

## Initialization

*ifilename* -- the output file's name (in double-quotes).

*iformat* -- a flag to choose output file format (note: Csound versions older than 5.0 may only support formats 0, 1, and 2):

- 0 - 32-bit floating point samples without header (binary PCM multichannel file)
- 1 - 16-bit integers without header (binary PCM multichannel file)
- 2 - 16-bit integers with a header. The header type depends on the render (-o) format. For example, if the user chooses the AIFF format (using the *-A* flag), the header format will be AIFF type.
- 3 - u-law samples with a header (see *iformat=2*).
- 4 - 16-bit integers with a header (see *iformat=2*).
- 5 - 32-bit integers with a header (see *iformat=2*).
- 6 - 32-bit floats with a header (see *iformat=2*).
- 7 - 8-bit unsigned integers with a header (see *iformat=2*).
- 8 - 24-bit integers with a header (see *iformat=2*).
- 9 - 64-bit floats with a header (see *iformat=2*).

In addition, Csound versions 5.0 and later allow for explicitly selecting a particular header type by specifying the format as 10 \* fileType + sampleFormat, where fileType may be 1 for WAV, 2 for AIFF, 3 for raw (headerless) files, and 4 for IRCAM; sampleFormat is one of the above values in the range 0 to 9, except sample format 0 is taken from the command line (-o), format 1 is 8-bit signed integers, and format 2 is a-law. So, for example, *iformat=25* means 32-bit integers with AIFF header.

## Performance

*aout1, ... aoutN* -- signals to be written to the file. In the case of raw files, the expected range of audio signals is determined by the selected sample format; for sound files with a header like WAV and AIFF,

the audio signals should be in the range -0dbfs to 0dbfs.

*fout* (file output) writes samples of audio signals to a file with any number of channels. Channel number depends by the number of *aoutN* variables (i.e. a mono signal with only an a-rate argument, a stereo signal with two a-rate arguments etc.) Maximum number of channels is fixed to 64. Multiple *fout* opcodes can be present in the same instrument, referring to different files.

Notice that, unlike *out*, *outs* and *outq*, *fout* does not zero the audio variable so you must zero it after calling it. If polyphony is to be used, you can use *vincr* and *clear* opcodes for this task.

Notice that *fout* and *foutk* can use either a string containing a file pathname, or a handle-number generated by *fiopen*. Whereas, with *fouti* and *foutir*, the target file can be only specified by means of a handle-number.

## Note

If you are using *fout* to generate an audio file for the global output of csound, you might want to use the *monitor* opcode, which can tap the output buffer, to avoid having to route

# Examples

Here is a simple example of the *fout* opcode. It uses the file *fout.csd* [examples/fout.csd].

### Example 316. Example of the *fout* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac      ;;;realtime audio out
;-iadc      ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime output leave only the line below:
;-o fout.wav -W ;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

giSine ftgen 0, 0, 2^10, 10, 1

instr 1
    asig poscil3 .5, 880, giSine
;write a raw file: 32 bits with header
    fout "fout_880.wav", 15, asig
    outs asig, asig

endin

instr 2

# fouti

*fouti* — Outputs i-rate signals of an arbitrary number of channels to a specified file.

## Description

*fouti* output  $N$  i-rate signals to a specified file of  $N$  channels.

## Syntax

```
fouti ihandle, iformat, iflag, iout1 [, iout2, iout3,...,ioutN]
```

## Initialization

*ihandle* -- a number which specifies this file.

*iformat* -- a flag to choose output file format:

- 0 - floating point in text format
- 1 - 32-bit floating point in binary format

*iflag* -- choose the mode of writing to the ASCII file (valid only in ASCII mode; in binary mode *iflag* has no meaning, but it must be present anyway). *iflag* can be a value chosen among the following:

- 0 - line of text without instrument prefix
- 1 - line of text with instrument prefix (see below)
- 2 - reset the time of instrument prefixes to zero (to be used only in some particular cases. See below)

*iout*,..., *ioutN* -- values to be written to the file

## Performance

*fouti* and *foutir* write i-rate values to a file. The main use of these opcodes is to generate a score file during a realtime session. For this purpose, the user should set *iformat* to 0 (text file output) and *iflag* to 1, which enable the output of a prefix consisting of the strings *inum*, *actiontime*, and *duration*, before the values of *iout1*...*ioutN* arguments. The arguments in the prefix refer to instrument number, action time and duration of current note.

Notice that *fout* and *foutk* can use either a string containing a file pathname, or a handle-number generated by *fiopen*. Whereas, with *fouti* and *foutir*, the target file can be only specified by means of a handle-number.

## Examples

Here is an example of the *fouti* opcode. It uses the file *fouti.csd* [examples/fouti.csd].

### Example 318. Example of the fouti opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# foutir

**foutir** — Outputs i-rate signals from an arbitrary number of channels to a specified file.

## Description

*foutir* output  $N$  i-rate signals to a specified file of  $N$  channels.

## Syntax

```
foutir ihandle, iformat, iflag, iout1 [, iout2, iout3,...,ioutN]
```

## Initialization

*ihandle* -- a number which specifies this file.

*iformat* -- a flag to choose output file format:

- 0 - floating point in text format
- 1 - 32-bit floating point in binary format

*iflag* -- choose the mode of writing to the ASCII file (valid only in ASCII mode; in binary mode *iflag* has no meaning, but it must be present anyway). *iflag* can be a value chosen among the following:

- 0 - line of text without instrument prefix
- 1 - line of text with instrument prefix (see below)
- 2 - reset the time of instrument prefixes to zero (to be used only in some particular cases. See below)

*iout*, ..., *ioutN* -- values to be written to the file

## Performance

*fouti* and *foutir* write i-rate values to a file. The main use of these opcodes is to generate a score file during a realtime session. For this purpose, the user should set *iformat* to 0 (text file output) and *iflag* to 1, which enable the output of a prefix consisting of the strings *inum*, *actiontime*, and *duration*, before the values of *iout1*...*ioutN* arguments. The arguments in the prefix refer to instrument number, action time and duration of current note.

The difference between *fouti* and *foutir* is that, in the case of *fouti*, when *iflag* is set to 1, the duration of the first opcode is undefined (so it is replaced by a dot). Whereas, *foutir* is defined at the end of note, so the corresponding text line is written only at the end of the current note (in order to recognize its duration). The corresponding file is linked by the *ihandle* value generated by the *fiopen* opcode. So *fouti* and *foutir* can be used to generate a Csound score while playing a realtime session.

Notice that *fout* and *foutk* can use either a string containing a file pathname, or a handle-number generated by *fiopen*. Whereas, with *fouti* and *foutir*, the target file can be only specified by means of a handle-number.

## Examples

Here is an example of the foutir opcode. It uses the file *foutir.csd* [examples/foutir.csd] and creates a list "foutir.sco". It can be used as a score file.

### Example 319. Example of the foutir opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# foutk

**foutk** — Outputs k-rate signals of an arbitrary number of channels to a specified file, in raw (headerless) format.

## Description

*foutk* outputs  $N$  k-rate signals to a specified file of  $N$  channels.

## Syntax

```
foutk ifilename, iformat, kout1 [, kout2, kout3,...,koutN]
```

## Initialization

*ifilename* -- the output file's name (in double-quotes).

*iformat* -- a flag to choose output file format (note: Csound versions older than 5.0 may only support formats 0 and 1):

- 0 - 32-bit floating point samples without header (binary PCM multichannel file)
- 1 - 16-bit integers without header (binary PCM multichannel file)
- 2 - 16-bit integers without header (binary PCM multichannel file)
- 3 - u-law samples without header
- 4 - 16-bit integers without header
- 5 - 32-bit integers without header
- 6 - 32-bit floats without header
- 7 - 8-bit unsigned integers without header
- 8 - 24-bit integers without header
- 9 - 64-bit floats without header

## Performance

*kout1,...koutN* -- control-rate signals to be written to the file. The expected range of the signals is determined by the selected sample format.

*foutk* operates in the same way as *fout*, but with k-rate signals. *iformat* can be set only in the range 0 to 9, or 0 to 1 with an old version of Csound.

Notice that *fout* and *foutk* can use either a string containing a file pathname, or a handle-number generated by *fiopen*. Whereas, with *fouti* and *foutir*, the target file can be only specified by means of a handle-number.

# fprintks

fprintks — Similar to printk but prints to a file.

## Description

Similar to *printks* but prints to a file.

## Syntax

```
fprintks "filename", "string", [, kval1] [, kval2] [...]
```

## Initialization

"*filename*" -- name of the output file.

"*string*" -- the text string to be printed. Can be up to 8192 characters and must be in double quotes.

## Performance

*kval1*, *kval2*, ... (optional) -- The k-rate values to be printed. These are specified in "*string*" with the standard C value specifier (%f, %d, etc.) in the order given.

*fprintks* is similar to the *printks* opcode except it outputs to a file and doesn't have a *itime* parameter. For more information about output formatting, please look at *printks*'s documentation.

## Examples

Here is an example of the fprintks opcode. It uses the file *fprintks.csd* [examples/fprintks.csd].

### Example 320. Example of the fprintks opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out    Audio in
-odac          -iadc   ;;;RT audio I/O
; For Non-realtime ouput leave only the line below:
; -o fprintks.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

/* Written by Matt Ingalls, edited by Kevin Conder. */
; Initialize the global variables.
sr = 44100
kr = 4410
ksmps = 10
nchnls = 1

; Instrument #1 - a score generator example.
instr 1
; K-rate stuff.
kstart init 0
```

```
kdur linrand 10
kpitch linrand 8

; Printing to to a file called "my.sco".
fprintks "my.sco", "i1\t%2.2f\t%2.2f\t%2.2f\n", kstart, kdur, 4+kpitch

knext linrand 1
kstart = kstart + knext
endin

</CsInstruments>
<CsScore>

/* Written by Matt Ingalls, edited by Kevin Conder. */
; Play Instrument #1.
i 1 0 0.001

</CsScore>
</CsoundSynthesizer>
```

This example will generate a file called “my.sco”. It should contain lines like this:

```
i1      0.00    3.94    10.26
i1      0.20    3.35    6.22
i1      0.67    3.65    11.33
i1      1.31    1.42    4.13
```

Here is an example of the fprintks opcode, which converts a standard MIDI file to a csound score. It uses the file *fprintks-2.csd* [examples/fprintks-2.csd].

### Example 321. Example of the fprintks opcode to convert a MIDI file to a csound score.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out   Audio in   No messages
; -odac        -iadc     -d      ;RT audio I/O
; For Non-realtime output leave only the line below:
-n -Fmidichn_advanced.mid
;Don't write audio output to disk and use the file midichn_advanced.mid as MIDI input
</CsOptions>
<CsInstruments>

sr      =  48000
ksmps   =  16
nchnls  =  2

;Example by Jonathan Murphy 2007

; assign all midi events to instr 1000
massign 0, 1000
pgmassign 0, 1000

instr 1000

ktim timeinsts

kst, kch, kdl, kd2 midiin
if (kst != 0) then
; p4 = MIDI event type  p5 = channel  p6= data1  p7= data2
    fprintks "MIDI2cs.sco", "i1\t%f\t%f\t%d\t%d\t%d\n", ktim, 1/kr, kst, kch, kdl,
endif

endin

</CsInstruments>
<CsScore>
```

```
i1000 0 10000
e
</CsScore>
</CsoundSynthesizer>
```

This example will generate a file called “MIDI2cs.sco” containing i-events according to the MIDI file

Here is an advanced example of the `fprintks` opcode, which generates scores for Csound. It uses the file `scogen-2.csd` [examples/scogen.csd].

### Example 322. Example of the `fprintks` opcode to create a Csound score file generator using Csound.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out   Audio in    No messages
; -odac        -iadc     -d      ;;;RT audio I/O
; For Non-realtime ouput leave only the line below:
-n
;Don't write audio ouput to disk
</CsOptions>

# fprints

fprints — Similar to prints but prints to a file.

## Description

Similar to *prints* but prints to a file.

## Syntax

```
fprints "filename", "string" [, ival1] [, ival2] [...]
```

## Initialization

"*filename*" -- name of the output file.

"*string*" -- the text string to be printed. Can be up to 8192 characters and must be in double quotes.

*ival1, ival2, ...* (optional) -- The i-rate values to be printed. These are specified in "*string*" with the standard C value specifier (%f, %d, etc.) in the order given.

## Performance

*fprints* is similar to the *prints* opcode except it outputs to a file. For more information about output formatting, please look at *prints's documentation*.

## Examples

Here is an example of the fprints opcode. It uses the file *fprints.csd* [examples/fprints.csd].

### Example 323. Example of the fprints opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out    Audio in
-odac          -iadc   ;;;RT audio I/O

# frac

frac — Returns the fractional part of a decimal number.

## Description

Returns the fractional part of  $x$ .

## Syntax

```
frac(x) (init-rate or control-rate args; also works at audio rate in Csound5)
```

where the argument within the parentheses may be an expression. Value converters perform arithmetic translation from units of one kind to units of another. The result can then be a term in a further expression.

## Examples

Here is an example of the frac opcode. It uses the file *frac.csd* [examples/frac.csd].

### Example 324. Example of the frac opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out   Audio in
-o dac -iadc ;;;RT audio I/O
; For Non-realtime output leave only the line below:
; -o frac.wav -W ;; for file output any platform
</CsOptions>
<CsInstruments>

; Initialize the global variables.
sr = 44100
kr = 4410
ksmps = 10
nchnls = 1

; Instrument #1.
instr 1
    i1 = 16 / 5
    i2 = frac(i1)

    print i2
endin

</CsInstruments>
<CsScore>

; Play Instrument #1 for one second.
i 1 0 1
e

</CsScore>
</CsoundSynthesizer>
```

Its output should include a line like this:

```
instr 1: i2 = 0.200
```

# fractalnoise

fractalnoise — A fractal noise generator.

## Description

A fractal noise generator implemented as a white noise filtered by a cascade of 15 first-order filters.

## Syntax

```
ares fractalnoise kamp, kbta
```

## Performance

*kamp* -- amplitude.

*kbta* -- spectral parameter related to the fractal dimension

- 0 - white
- 1 - pink
- 2 - brown

## Examples

Here is an example of the `fractalnoise` opcode. It uses the file `fractalnoise.csd` [examples/fractalnoise.csd].

### Example 325. Example of the `fractalnoise` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# framebuffer

**framebuffer** — Read audio signals into 1 dimensional k-rate arrays and vice-versa with a specified buffer size.

## Description

*framebuffer* converts audio signals into a 1 dimensional k-rate array of a specified size. The size of the k-rate array must be larger than *ksmps*. It also converts 1 dimensional k-rate arrays back into audio signals, the k-rate arrays must be uninitialised and also be larger than *ksmps* in size. The buffer works as a circular buffer and may be used for doing frame based audio processing such as spectral analysis/synthesis or as a simple delay line.

## Syntax

```
kout[] framebuffer ain, isize  
  
aout framebuffer kin, isize
```

## Initialization

*isize* -- The amount of samples that the buffer will contain.

## Performance

*kout[]* -- The k-rate array output from the framebuffer. *ain* -- The audio signal input to the framebuffer.

*aout* -- The audio signal output from the framebuffer. *kin* -- The k-rate array input to the framebuffer.

## Examples

Here is a simple example of the framebuffer opcode. It uses the file *framebuffer.csd* [examples/framebuffer.csd].

### Example 326. Example of the framebuffer opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# freeverb

freeverb — Opcode version of Jezar's Freeverb

## Description

freeverb is a stereo reverb unit based on Jezar's public domain C++ sources, composed of eight parallel comb filters on both channels, followed by four allpass units in series. The filters on the right channel are slightly detuned compared to the left channel in order to create a stereo effect.

## Syntax

```
aoutL, aoutR freeverb ainL, ainR, kRoomSize, kHFDDamp[, iSRate[, iSkip]]
```

## Initialization

*iSRate* (optional, defaults to 44100): adjusts the reverb parameters for use with the specified sample rate (this will affect the length of the delay lines in samples, and, as of the latest CVS version, the high frequency attenuation). Only integer multiples of 44100 will reproduce the original character of the reverb exactly, so it may be useful to set this to 44100 or 88200 for an orchestra sample rate of 48000 or 96000 Hz, respectively. While *iSRate* is normally expected to be close to the orchestra sample rate, different settings may be useful for special effects.

*iSkip* (optional, defaults to zero): if non-zero, initialization of the opcode will be skipped, whenever possible.

## Performance

*ainL, ainR* -- input signals; usually both are the same, but different inputs can be used for special effect

### Note

It is recommended to process the input signal(s) with the denorm opcode in order to avoid denormalized numbers which could significantly increase CPU usage in some cases

*aoutL, aoutR* -- output signals for left and right channel

*kRoomSize* (range: 0 to 1) -- controls the length of the reverb, a higher value means longer reverb. Settings above 1 may make the opcode unstable.

*kHFDDamp* (range: 0 to 1): high frequency attenuation; a value of zero means all frequencies decay at the same rate, while higher settings will result in a faster decay of the high frequency range.

## Examples

Here is an example of the *freeverb* opcode. It uses the file *freeverb.csd* [examples/freeverb.csd].

### Example 327. An example of the freeverb opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# ftchnls

ftchnls — Returns the number of channels in a stored function table.

## Description

Returns the number of channels in a stored function table.

## Syntax

```
ftchnls(x) (init-rate args only)
```

## Performance

Returns the number of channels of a *GEN01* table, determined from the header of the original file. If the original file has no header or the table was not created by these *GEN01*, *ftchnls* returns -1.

## Examples

Here is an example of the *ftchnls* opcode. It uses the files *ftchnls.csd* [examples/ftchnls.csd], *mary.wav* [examples/mary.wav], and *kickroll.wav* [examples/kickroll.wav].

### Example 328. Example of the ftchnls opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
;-odac    ;;;realtime audio out
-iadc    ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime output leave only the line below:
;-o ftchnls.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1
ichnls = ftchnls(p4)
print ichnls

if (ichnls == 1) then
  asigL oscil3 .8, 4, p4
  asigR = asigL
elseif (ichnls == 2) then
  asigL, asigR oscil3 .8, 4, p4
;safety precaution if not mono or stereo
else
  asigL = 0
  asigR = 0
endif
outs asigL, asigR
```

```
endin
</CsInstruments>
<CsScore>
f 1 0 0 1 "mary.wav" 0 0 0
f 2 0 0 1 "kickroll.wav" 0 0 0

i 1 0 3 1 ;mono file
i 1 + 2 2 ;stereo file
e
</CsScore>
</CsoundSynthesizer>
```

The audio file “mary.wav” is monophonic, the audio file “kickroll.wav” is stereophonic, so its output should include lines like these:

```
instr 1: ichnls = 1.000
instr 1: ichnls = 2.000
```

# ftconv

ftconv — Low latency multichannel convolution, using a function table as impulse response source.

## Description

Low latency multichannel convolution, using a function table as impulse response source. The algorithm is to split the impulse response to partitions of length determined by the *iplen* parameter, and delay and mix partitions so that the original, full length impulse response is reconstructed without gaps. The output delay (latency) is *iplen* samples, and does not depend on the control rate, unlike in the case of other convolve opcodes.

## Syntax

```
a1[, a2[, a3[, ... a8]]] ftconv ain, ift, iplen[, iskipsamples \
[, iirlen[, iskipinit]]]
```

## Initialization

*ift* -- source ftable number. The table is expected to contain interleaved multichannel audio data, with the number of channels equal to the number of output variables (a1, a2, etc.). An interleaved table can be created from a set of mono tables with *GEN52*.

*iplen* -- length of impulse response partitions, in sample frames; must be an integer power of two. Lower settings allow for shorter output delay, but will increase CPU usage.

*iskipsamples* (optional, defaults to zero) -- number of sample frames to skip at the beginning of the table. Useful for reverb responses that have some amount of initial delay. If this delay is not less than *iplen* samples, then setting *iskipsamples* to the same value as *iplen* will eliminate any additional latency by *ftconv*.

*iirlen* (optional) -- total length of impulse response, in sample frames. The default is to use all table data (not including the guard point).

*skipinit* (optional, defaults to zero) -- if set to any non-zero value, skip initialization whenever possible without causing an error.

## Performance

*ain* -- input signal.

*a1* ... *a8* -- output signal(s).

## Example

Here is an example of the ftconv opcode. It uses the file *ftconv.csd* [examples/ftconv.csd].

### Example 329. Example of the ftconv opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# ftcps

ftcps — Returns the base frequency of a stored function table in Hz.

## Description

Returns the base frequency of a stored function table in Hz..

## Syntax

```
ftcps(x) (init-rate args only)
```

## Performance

Returns the base frequency of stored function table, number *x*. *ftcps* is designed for tables storing audio waveforms read from files (see *GEN01*).

*ftcps* returns -1 in case of an error (no base frequency set in table or non-existent table).

## Examples

Here is an example of the ftcps opcode.

### Example 330. Example of the ftcps opcode.

# ftgen

ftgen — Generate a score function table from within the orchestra.

## Description

Generate a score function table from within the orchestra.

## Syntax

```
gir ftgen ifn, itime, isize, igen, iarga [, iargb ] [...]
```

## Initialization

*gir* -- either a requested or automatically assigned table number above 100.

*ifn* -- requested table number If *ifn* is zero, the number is assigned automatically and the value placed in *gir*. Any other value is used as the table number

*itime* -- is ignored, but otherwise corresponds to p2 in the score *f statement*.

*isize* -- table size. Corresponds to p3 of the score *f statement*.

*igen* -- function table *GEN* routine. Corresponds to p4 of the score *f statement*.

*iarga, iargb, ...* -- function table arguments. Correspond to p5 through *pn* of the score *f statement*.

## Performance

This is equivalent to table generation in the score with the *f statement*.

### Note

Csound was originally designed to support tables with power of two sizes only. Though this has changed in recent versions (you can use any size by using a negative number), many opcodes will not accept them.

### Warning

Although Csound will not protest if ftgen is used inside instr-endin statements, this is not the intended or supported use, and must be handled with care as it has global effects. (In particular, a different size usually leads to relocation of the table, which may cause a crash or otherwise erratic behaviour.)

## Examples

Here is an example of the ftgen opcode. It uses the file *ftgen.csd* [examples/ftgen.csd].

### Example 332. Example of the ftgen opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>

# ftgenonce

ftgenonce — Generate a function table from within an instrument definition, without duplication of data.

## Description

Enables the creation of function tables entirely inside instrument definitions, without any duplication of data.

The ftgenonce opcode is designed to simplify writing instrument definitions that can be re-used in different orchestras simply by #including them and plugging them into some output instrument. There is no need to define function tables either in the score, or in the orchestra header.

The ftgenonce opcode is similar to ftgentmp, and has identical arguments. However, function tables are neither duplicated nor deleted. Instead, all of the arguments to the opcode are concatenated to form the key to a lookup table that points to the function table number. Thus, every request to ftgenonce with the same arguments receives the same instance of the function table data. Every change in the value of any ftgenonce argument causes the creation of a new function table.

## Syntax

```
ifno ftgenonce ip1, ip2dummy, isize, igen, iarga, iargb, ...
```

## Initialization

*ifno* -- an automatically assigned table number.

*ip1* -- the number of the table to be generated or 0 if the number is to be assigned.

*ip2dummy* -- ignored.

*isize* -- table size. Corresponds to p3 of the score *f statement*.

*igen* -- function table *GEN* routine. Corresponds to p4 of the score *f statement*.

*iarga, iargb, ...* -- function table arguments. Correspond to p5 through *pn* of the score *f statement*.

### Note

Csound was originally designed to support tables with power of two sizes only. Though this has changed in recent versions (you can use any size by using a negative number), many opcodes will not accept them.

## Examples

Here is an example of the ftgenonce opcode. It uses the file *ftgenonce.csd* [examples/ftgenonce.csd].

### Example 334. Example of the ftgenonce opcode.

```
<CsoundSynthesizer>

# ftgentmp

**ftgentmp** — Generate a score function table from within the orchestra, which is deleted at the end of the note.

## Description

Generate a score function table from within the orchestra, which is optionally deleted at the end of the note.

## Syntax

```
ifno ftgentmp ip1, ip2dummy, isize, igen, iarga, iargb, ...
```

## Initialization

*ifno* -- either a requested or automatically assigned table number above 100.

*ip1* -- the number of the table to be generated or 0 if the number is to be assigned, in which case the table is deleted at the end of the note activation.

*ip2dummy* -- ignored.

*isize* -- table size. Corresponds to p3 of the score *f statement*.

*igen* -- function table *GEN* routine. Corresponds to p4 of the score *f statement*.

*iarga, iargb, ...* -- function table arguments. Correspond to p5 through *pn* of the score *f statement*.

### Note

Csound was originally designed to support tables with power of two sizes only. Though this has changed in recent versions (you can use any size by using a negative number), many opcodes will not accept them.

## Examples

Here is an example of the **ftgentmp** opcode. It uses the file *ftgentmp.csd* [examples/ftgentmp.csd].

### Example 335. Example of the **ftgentmp** opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# ftlen

ftlen — Returns the size of a stored function table.

## Description

Returns the size of a stored function table.

## Syntax

```
ftlen(x) (init-rate args only)
```

## Performance

Returns the size (number of points, excluding guard point) of stored function table, number *x*. While most units referencing a stored table will automatically take its size into account (so tables can be of arbitrary length), this function reports the actual size if that is needed. Note that *flen* will always return a power-of-2 value, i.e. the function table guard point (see *f Statement*) is not included. As of Csound version 3.53, *ftlen* works with deferred function tables (see *GEN01*).

*ftlen* differs from *nsamp* in that *nsamp* gives the number of sample frames loaded, while *ftlen* gives the total number of samples without the guard point. For example, with a stereo sound file of 10000 samples, *ftlen()* would return 19999 (i.e. a total of 20000 mono samples, not including a guard point), but *nsamp()* returns 10000.

## Examples

Here is an example of the *ftlen* opcode. It uses the file *ftlen.csd* [examples/ftlen.csd], *fox.wav* [examples/fox.wav] and *beats.wav* [examples/beats.wav].

### Example 336. Example of the ftlen opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac     ;;;realtime audio out
;-iadc    ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime output leave only the line below:
;-o ftlen.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1
ift = ftlen(p4)
print ift
aout oscil3 .8, 4, p4
outs aout, aout
```

```
endin
</CsInstruments>
<CsScore>

f 1 0 0 1 "fox.wav" 0 0 0 ;Csound computes tablesize
f 2 0 0 1 "beats.wav" 0 0 0 ;Csound computes tablesize

i 1 0 3 1 ;"fox.wav"
i 1 3 3 2 ;"beats.wav"

e
</CsScore>
</CsoundSynthesizer>
```

The audio file “fox.wav” is 121569 samples long, “beats.wav” has a length of 88200 samples. The flen opcode reports them as 121568 and 88199 samples, because it reserves 1 point for the guard point. Its output should include lines like these:

```
instr 1: ift = 121568.000
instr 1: ift = 88199.000
```

# ftload

`ftload` — Load a set of previously-allocated tables from a file.

## Description

Load a set of previously-allocated tables from a file.

## Syntax

```
ftload "filename", iflag, ifn1 [, ifn2] [...]
```

## Initialization

*"filename"* -- A quoted string containing the name of the file to load.

*iflag* -- Type of the file to load/save. (0 = binary file, Non-zero = text file)

*ifn1, ifn2, ...* -- Numbers of tables to load.

## Performance

*ftload* loads a list of tables from a file. (The tables have to be already allocated though.) The file's format can be binary or text.

### Warning

The file's format is not compatible with a WAV-file and is not endian-safe.

## Examples

See the example for *ftsave*.

# ftloadk

`ftloadk` — Load a set of previously-allocated tables from a file.

## Description

Load a set of previously-allocated tables from a file.

## Syntax

```
ftloadk "filename", ktrig, iflag, ifn1 [, ifn2] [...]
```

## Initialization

*"filename"* -- A quoted string containing the name of the file to load.

*iflag* -- Type of the file to load/save. (0 = binary file, Non-zero = text file)

*ifn1, ifn2, ...* -- Numbers of tables to load.

## Performance

*ktrig* -- The trigger signal. Load the file each time it is non-zero.

*ftloadk* loads a list of tables from a file. (The tables have to be already allocated though.) The file's format can be binary or text. Unlike *ftload*, the loading operation can be repeated numerous times within the same note by using a trigger signal.

### Warning

The file's format is not compatible with a WAV-file and is not endian-safe.

# ftlptim

**ftlptim** — Returns the loop segment start-time of a stored function table number.

## Description

Returns the loop segment start-time of a stored function table number.

## Syntax

```
ftlptim(x) (init-rate args only)
```

## Performance

Returns the loop segment start-time (in seconds) of stored function table number *x*. This reports the duration of the direct recorded attack and decay parts of a sound sample, prior to its looped segment. Returns zero (and a warning message) if the sample does not contain loop points.

## Examples

Here is an example of the *ftlptim* opcode. It uses the files *ftlptim.csd* [examples/ftlptim.csd], and *Church.wav* [examples/Church.wav].

### Example 337. Example of the *ftlptim* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac     ;;;realtime audio out
;-iadc    ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime output leave only the line below:

# ftmorph

ftmorph — Morphs between multiple ftables as specified in a list.

## Description

Uses an index into a table of ftable numbers to morph between adjacent tables in the list. This morphed function is written into the table referenced by *ireshfn* on every k-cycle.

## Syntax

```
ftmorph kftndx, iftn, ireshfn
```

## Initialization

*iftfn* -- The table containing the numbers of any existing tables which are used for the morphing.

*ireshfn* -- Table number of the morphed function

The length of all the tables in *iftfn* must equal the length of *ireshfn*.

## Performance

*kftndx* -- the index into the *iftfn* table.

If *iftfn* contains (6, 4, 6, 8, 7, 4):

- *kftndx=4* will write the contents of f7 into *ireshfn*.
- *kftndx=4.5* will write the average of the contents of f7 and f4 into *ireshfn*.

### Note

*ireshfn* is only updated if the morphing index changes its value, if *kftndx* is static, no writing to *ireshfn* will occur.

## Examples

Here is an example of the ftmorph opcode. It uses the file *ftmorph.csd* [examples/ftmorph.csd].

### Example 338. Example of the ftmorph opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# ftsave

ftsave — Save a set of previously-allocated tables to a file.

## Description

Save a set of previously-allocated tables to a file.

## Syntax

```
ftsave "filename", iflag, ifn1 [, ifn2] [...]
```

## Initialization

"*filename*" -- A quoted string containing the name of the file to save.

*iflag* -- Type of the file to save. (0 = binary file, Non-zero = text file)

*ifn1, ifn2, ...* -- Numbers of tables to save.

## Performance

*ftsave* saves a list of tables to a file. The file's format can be binary or text.

### Warning

The file's format is not compatible with a WAV-file and is not endian-safe.

## Examples

Here is an example of the ftsave opcode. It uses the file *ftsave.csd* [examples/ftsave.csd].

### Example 339. Example of the ftsave opcode.

# ftsr

ftsr — Returns the sampling-rate of a stored function table.

## Description

Returns the sampling-rate of a stored function table.

## Syntax

```
ftsr(x) (init-rate args only)
```

## Performance

Returns the sampling-rate of a *GEN01* generated table. The sampling-rate is determined from the header of the original file. If the original file has no header or the table was not created by these *GEN01*, *ftsr* returns 0. New in Csound version 3.49.

## Examples

Here is an example of the ftsr opcode. It uses the file *ftsr.csd* [examples/ftsr.csd].

### Example 340. Example of the ftsr opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# gain

`gain` — Adjusts the amplitude audio signal according to a root-mean-square value.

## Description

Adjusts the amplitude audio signal according to a root-mean-square value.

## Syntax

```
ares gain asig, krms [, ihp] [, iskip]
```

## Initialization

*ihp* (optional, default=10) -- half-power point (in Hz) of a special internal low-pass filter. The default value is 10.

*iskip* (optional, default=0) -- initial disposition of internal data space (see *reson*). The default value is 0.

## Performance

*asig* -- input audio signal

*gain* provides an amplitude modification of *asig* so that the output *ares* has rms power equal to *krms*. *rms* and *gain* used together (and given matching *ihp* values) will provide the same effect as *balance*.

## Examples

Here is an example of the gain opcode. It uses the file *gain.csd* [examples/gain.csd].

### Example 341. Example of the gain opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# gainslider

gainslider — An implementation of a logarithmic gain curve which is similar to the gainslider~ object from Cycling 74 Max / MSP.

## Description

This opcode is intended for use to multiply by an audio signal to give a console mixer like feel. There is no bounds in the source code so you can for example give higher than 127 values for extra amplitude but possibly clipped audio.

## Syntax

```
kout gainslider kindex
```

## Performance

*kindex* -- Index value. Nominal range from 0-127. For example a range of 0-152 will give you a range from -# to +18.0 dB.

*kout* -- Scaled output.

## Examples

Here is an example of the gainslider opcode. It uses the file *gainslider.csd* [examples/gainslider.csd].

### Example 342. Example of the gainslider opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# gauss

gauss — Gaussian distribution random number generator.

## Description

Gaussian distribution random number generator. This is an x-class noise generator.

## Syntax

```
ares gauss krang  
ires gauss krang  
kres gauss krang
```

## Performance

*krange* -- the range of the random numbers (*-krange* to *+krange*). Outputs both positive and negative numbers.

*gauss* returns random numbers following a normal distribution centered around 0.0 (mu = 0.0) with a variance (sigma) of *krange* / 3.83. Thus more than 99.99% of the random values generated are in the range *-krange* to *+krange*. If a mean value different of 0.0 is desired, this mean value has to be added to the generated numbers (see example below).

For more detailed explanation of these distributions, see:

1. C. Dodge - T.A. Jerse 1985. Computer music. Schirmer books. pp.265 - 286
2. D. Lorrain. A panoply of stochastic cannons. In C. Roads, ed. 1989. Music machine . Cambridge, Massachusetts: MIT press, pp. 351 - 379.

## Examples

Here is an example of the gauss opcode. It uses the file *gauss.csd* [examples/gauss.csd].

### Example 343. Example of the gauss opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>  
<CsOptions>  
-d -o dac  
</CsOptions>  
<CsInstruments>  
instr 1  
irange = p4  
imu = p5  
isamples = p6
```

```
indx      = 0
icount   = 1
ix       = 0.0
ix2      = 0.0

loop:
i1      gauss    irange
i1      =      i1 + imu
ix      =
ix2      =      ix2 + i1*i1
if i1 >= -(irange+imu) && i1 <= (irange+imu) then
  icount = icount+1
endif
  loop_lt indx, 1, isamples, loop

imean    =      ix / isamples           ;mean value
istd     =      sqrt(ix2/isamples - imean*imean) ;standard deviation
prints  "mean = %3.3f, std = %3.3f, ", imean, istd
prints  "samples inside the given range: %3.3f\n", icount*100.0/isamples
endin
</CsInstruments>
<CsScore>
i 1 0  0.1 1.0  0  100000 ; range = 1, mu = 0.0, sigma = 1/3.83 = 0.261
i 1 0.1 0.1 3.83 0  100000 ; range = 3.83, mu = 0.0, sigma = 1
i 1 0.2 0.1 5.745 2.7 100000 ; range = 5.745, mu = 2.7, sigma = 5.745/3.83 = 1.5
</CsScore>
</CsoundSynthesizer>
```

Its output should include lines like this:

```
mean = 0.000, std = 0.260, samples inside the given range: 99.993%
mean = 0.005, std = 0.999, samples inside the given range: 99.998%
mean = 2.700, std = 1.497, samples inside the given range: 100.000%
```

# gaussi

gaussi — Gaussian distribution random number generator with interpolation.

## Description

Gaussian distribution random number generator with controlled interpolation between values. This is an x-class noise generator.

## Syntax

```
ares gaussi krang, xamp, xcps  
  
ires gaussi krang, xamp, xcps  
  
kres gaussi krang, xamp, xcps
```

## Performance

*krange* -- the range of the random numbers (*-krange* to *+krange*). Outputs both positive and negative numbers.

*gauss* returns random numbers following a normal distribution centered around 0.0 (mu = 0.0) with a variance (sigma) of *krange* / 3.83. Thus more than 99.99% of the random values generated are in the range *-krange* to *+krange*. If a mean value different of 0.0 is desired, this mean value has to be added to the generated numbers (see example below).

For more detailed explanation of these distributions, see:

1. C. Dodge - T.A. Jerse 1985. Computer music. Schirmer books. pp.265 - 286
2. D. Lorrain. A panoply of stochastic cannons. In C. Roads, ed. 1989. Music machine . Cambridge, Massachusetts: MIT press, pp. 351 - 379.

*xamp* -- range over which random numbers are distributed.

*xcps* -- the frequency which new random numbers are generated.

## Examples

Here is an example of the gaussi opcode. It uses the file *gaussi.csd* [examples/gaussi.csd].

### Example 344. Example of the gaussi opcode.

# gausstrig

gausstrig — Random impulses around a certain frequency.

## Description

Generates random impulses around a certain frequency.

## Syntax

```
ares gausstrig kamp, kcps, kdev [, imode] [, ifrst1]
```

```
kres gausstrig kamp, kcps, kdev [, imode] [, ifrst1]
```

## Initialization

*imode* (optional, default=0) -- *imode* > 0 means better frequency modulation. If the frequency changes, the delay before the next impulse is calculated again. With the default mode we have the classic behavior of the GaussTrig ugen in SuperCollider, where the frequency modulation is bypassed during the delay time that precedes the next impulse.

*ifrst1* (optional, default=0) -- *ifrst1* > 0 changes the original behavior of the GaussTrig ugen. By default, it always generates an impulse in the very beginning. Otherwise, the first impulse appearance is random and depends on *kcps* and *kdev* parameters.

## Performance

*kamp* -- amplitude.

*kcps* -- the mean frequency over which random impulses are distributed.

*kdev* -- random deviation from mean ( $0 \leq dev < 1$ ).

## Examples

Here is an example of the gausstrig opcode. It uses the file *gausstrig.csd* [examples/gausstrig.csd].

# gbuzz

gbuzz — Output is a set of harmonically related cosine partials.

## Description

Output is a set of harmonically related cosine partials.

## Syntax

```
ares gbuzz xamp, xcps, knh, klh, kmul, ifn [, iphs]
```

## Initialization

*ifn* -- table number of a stored function containing a cosine wave. A large table of at least 8192 points is recommended.

*iphs* (optional, default=0) -- initial phase of the fundamental frequency, expressed as a fraction of a cycle (0 to 1). A negative value will cause phase initialization to be skipped. The default value is zero

## Performance

The buzz units generate an additive set of harmonically related cosine partials of fundamental frequency *xcps*, and whose amplitudes are scaled so their summation peak equals *xamp*. The selection and strength of partials is determined by the following control parameters:

*knh* -- total number of harmonics requested. If *knh* is negative, the absolute value is used. If *knh* is zero, a value of 1 is used.

*klh* -- lowest harmonic present. Can be positive, zero or negative. In *gbuzz* the set of partials can begin at any partial number and proceeds upwards; if *klh* is negative, all partials below zero will reflect as positive partials without phase change (since cosine is an even function), and will add constructively to any positive partials in the set.

*kmul* -- specifies the multiplier in the series of amplitude coefficients. This is a power series: if the *klh*th partial has a strength coefficient of *A*, the (*klh* + *n*)th partial will have a coefficient of *A* \* (*kmul* \*\* *n*), i.e. strength values trace an exponential curve. *kmul* may be positive, zero or negative, and is not restricted to integers.

*buzz* and *gbuzz* are useful as complex sound sources in subtractive synthesis. *buzz* is a special case of the more general *gbuzz* in which *klh* = *kmul* = 1; it thus produces a set of *knh* equal-strength harmonic partials, beginning with the fundamental. (This is a band-limited pulse train; if the partials extend to the Nyquist, i.e. *knh* = int(sr / 2 / fundamental freq.), the result is a real pulse train of amplitude *xamp*.)

Although both *knh* and *klh* may be varied during performance, their internal values are necessarily integer and may cause “pops” due to discontinuities in the output. *kmul*, however, can be varied during performance to good effect. *gbuzz* can be amplitude- and/or frequency-modulated by either control or audio signals.

N.B. This unit has its analog in *GEN11*, in which the same set of cosines can be stored in a function table for sampling by an oscillator. Although computationally more efficient, the stored pulse train has a fixed spectral content, not a time-varying one as above.

## Examples

Here is an example of the gbuzz opcode. It uses the file *gbuzz.csd* [examples/gbuzz.csd].

### Example 347. Example of the gbuzz opcode.

# gendy

gendy — Dynamic stochastic approach to waveform synthesis conceived by Iannis Xenakis.

## Description

Implementation of the *Génération Dynamique Stochastique* (GENDYN), a dynamic stochastic approach to waveform synthesis conceived by Iannis Xenakis.

## Syntax

```
ares gendy kamp, kampdist, kdurdist, kadpar, kddpar, kminfreq, kmaxfreq, \
kampscl, kdurscl [, initcps] [, knum]
```

```
kres gendy kamp, kampdist, kdurdist, kadpar, kddpar, kminfreq, kmaxfreq, \
kampscl, kdurscl [, initcps] [, knum]
```

## Initialization

*initcps* (optional, default=12) -- max number of control points.

## Performance

*kamp* -- amplitude.

*kampdist* -- choice of probability distribution for the next perturbation of the amplitude of a control point. The valid distributions are:

- 0 - LINEAR
- 1 - CAUCHY
- 2 - LOGIST
- 3 - HYPERBCOS
- 4 - ARCSINE
- 5 - EXPON
- 6 - SINUS (external k-rate signal)

If *kampdist*=6, the user can use an external k-rate signal through *kadpar*.

*kdurdist* -- choice of distribution for the perturbation of the current inter control point duration. See *kampdist* for the valid distributions. If *kdurdist*=6, the user can use an external k-rate signal through *kddpar*.

*kadpar* -- parameter for the *kampdist* distribution. Should be in the range of 0.0001 to 1.

*kddpar* -- parameter for the *kdurdist* distribution. Should be in the range of 0.0001 to 1.

*kminfreq* -- minimum allowed frequency of oscillation.

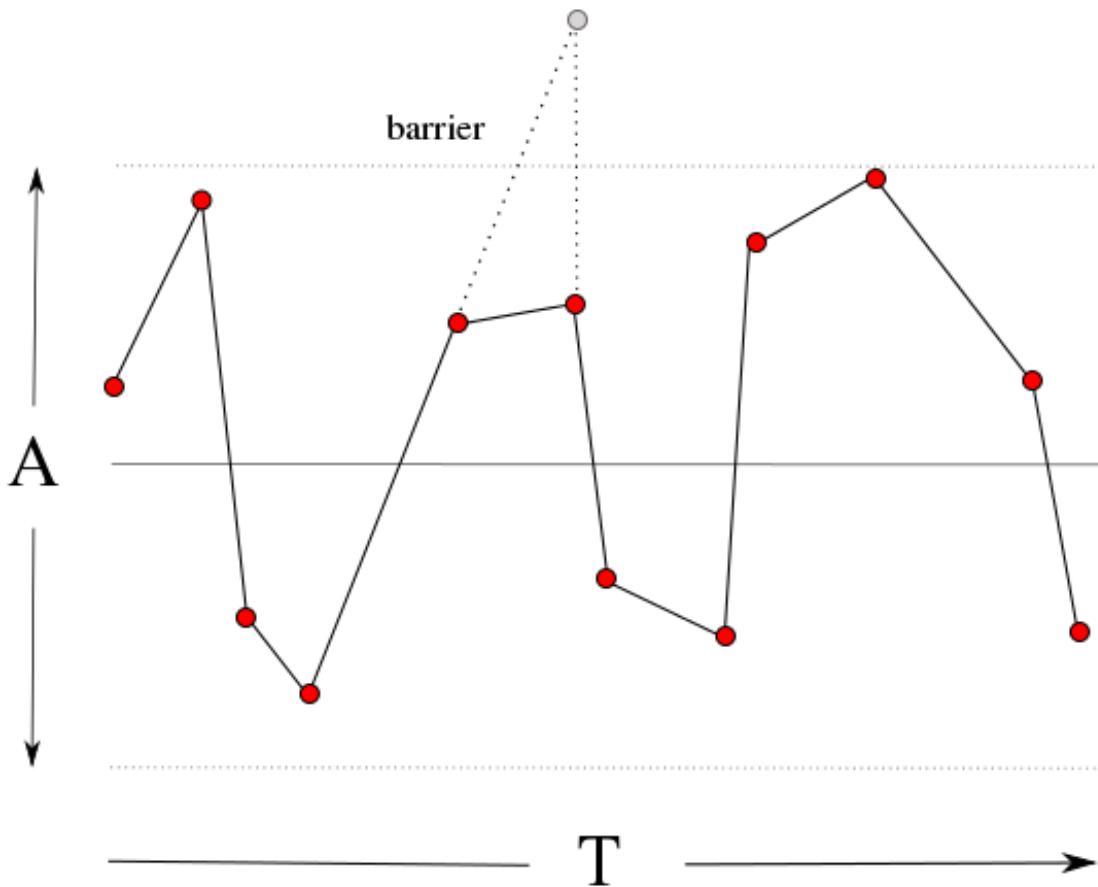

*kmaxfreq* -- maximum allowed frequency of oscillation.

*kampscl* -- multiplier for the distribution's delta value for amplitude (1.0 is full range).

*kdurscl* -- multiplier for the distribution's delta value for duration.

*knum* (optional, default=*initcps*) -- current number of utilized control points.

The waveform is generated by *knum* - 1 segments and is repeated in the time. The vertexes (control points) are moved according to a stochastic action and they are limited within the boundaries of a mirror formed by an amplitude barrier and a time barrier.

A repetition of the generated waveform with *knum*=12.

## Examples

Here is an example of the *gendy* opcode. It uses the file *gendy.csd* [examples/gendy.csd].

### Example 350. Example of the *gendy* opcode.

# gendyc

gendyc — Dynamic stochastic approach to waveform synthesis using cubic interpolation.

## Description

Implementation with cubic interpolation of the *Génération Dynamique Stochastique* (GENDYN), a dynamic stochastic approach to waveform synthesis conceived by Iannis Xenakis.

## Syntax

```
ares gendyc kamp, kampdist, kdurdist, kadpar, kddpar, kminfreq, kmaxfreq, \
kampscl, kdurscl [, initcps] [, knum]
```

```
kres gendyc kamp, kampdist, kdurdist, kadpar, kddpar, kminfreq, kmaxfreq, \
kampscl, kdurscl [, initcps] [, knum]
```

## Initialization

*initcps* (optional, default=12) -- max number of control points.

## Performance

*kamp* -- amplitude.

*kampdist* -- choice of probability distribution for the next perturbation of the amplitude of a control point. The valid distributions are:

- 0 - LINEAR
- 1 - CAUCHY
- 2 - LOGIST
- 3 - HYPERBCOS
- 4 - ARCSINE
- 5 - EXPON
- 6 - SINUS (external k-rate signal)

If *kampdist*=6, the user can use an external k-rate signal through *kadpar*.

*kdurdist* -- choice of distribution for the perturbation of the current inter control point duration. See *kampdist* for the valid distributions. If *kdurdist*=6, the user can use an external k-rate signal through *kddpar*.

*kadpar* -- parameter for the *kampdist* distribution. Should be in the range of 0.0001 to 1.

*kddpar* -- parameter for the *kdurdist* distribution. Should be in the range of 0.0001 to 1.

*kminfreq* -- minimum allowed frequency of oscillation.

*kmaxfreq* -- maximum allowed frequency of oscillation.

*kampscl* -- multiplier for the distribution's delta value for amplitude (1.0 is full range).

*kdurscl* -- multiplier for the distribution's delta value for duration.

*knum* (optional, default=*initcps*) -- current number of utilized control points.

The waveform is generated by *knum* - 1 segments and is repeated in the time. The vertexes (control points) are moved according to a stochastic action and they are limited within the boundaries of a mirror formed by an amplitude barrier and a time barrier.

## Examples

Here is an example of the *gendyc* opcode. It uses the file *gendyc.csd* [examples/gendyc.csd].

### Example 352. Example of the *gendyc* opcode.

# gendyx

gendyx — Variation of the dynamic stochastic approach to waveform synthesis conceived by Iannis Xenakis.

## Description

*gendyx* (gendy eXtended) is an implementation of the *Génération Dynamique Stochastique* (GENDYN), a dynamic stochastic approach to waveform synthesis conceived by Iannis Xenakis, using curves instead of segments.

## Syntax

```
ares gendyx kamp, kampdist, kdurdist, kadpar, kddpar, kminfreq, kmaxfreq, \
kampscl, kdurscl, kcurveup, kcurvedown [, initcps] [, knum]

kres gendyx kamp, kampdist, kdurdist, kadpar, kddpar, kminfreq, kmaxfreq, \
kampscl, kdurscl, kcurveup, kcurvedown [, initcps] [, knum]
```

## Initialization

*initcps* (optional, default=12) -- max number of control points.

## Performance

*kamp* -- amplitude.

*kampdist* -- choice of probability distribution for the next perturbation of the amplitude of a control point. The valid distributions are:

- 0 - LINEAR
- 1 - CAUCHY
- 2 - LOGIST
- 3 - HYPERBCOS
- 4 - ARCSINE
- 5 - EXPON
- 6 - SINUS (external k-rate signal)

If *kampdist*=6, the user can use an external k-rate signal through *kadpar*.

*kdurdist* -- choice of distribution for the perturbation of the current inter control point duration. See *kampdist* for the valid distributions. If *kdurdist*=6, the user can use an external k-rate signal through *kddpar*.

*kadpar* -- parameter for the *kampdist* distribution. Should be in the range of 0.0001 to 1.

*kddpar* -- parameter for the *kdurdist* distribution. Should be in the range of 0.0001 to 1.

*kminfreq* -- minimum allowed frequency of oscillation.

*kmaxfreq* -- maximum allowed frequency of oscillation.

*kampscl* -- multiplier for the distribution's delta value for amplitude (1.0 is full range).

*kdurscl* -- multiplier for the distribution's delta value for duration.

*kcurveup* -- controls the curve for the increasing amplitudes between two points; it has to be non negative.

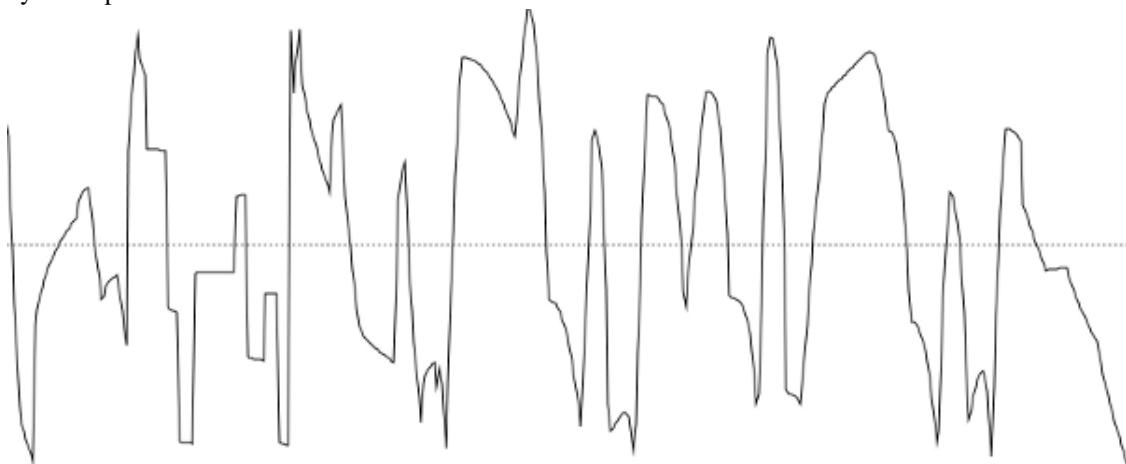

- 0: step function (like a sample & hold)
- <1: concave
- 1: linear (like gendy)
- >1: convex

*kcurredown* -- controls the curve for the decreasing amplitudes between two points; it has to be non negative.

- 0: step function
- <1: convex
- 1: linear
- >1: concave

*knum* (optional, default=*initcps*) -- current number of utilized control points.

The waveform is generated by *knum* - 1 curves and is repeated in the time. The vertexes (control points) are moved according to a stochastic action and they are limited within the boundaries of a mirror formed by an amplitude barrier and a time barrier.

Extract of a waveform generated with *gendyx*.

# getcfg

getcfg — Return Csound settings.

## Description

Return various configuration settings in Svalue as a string at init time.

## Syntax

```
Svalue getcfg iopt
```

## Initialization

*iopt* -- The parameter to be returned, can be one of:

- 1: the maximum length of string variables in characters; this is at least the value of the `-+max_str_len` command line option - 1.

### Note

In Csound6 there is no maximum string length so the returned value is meaningless

- 2: the input sound file name (-i), or empty if there is no input file
- 3: the output sound file name (-o), or empty if there is no output file
- 4: return "1" if real time audio input or output is being used, and "0" otherwise
- 5: return "1" if running in beat mode (-t command line option), and "0" otherwise
- 6: the host operating system name
- 7: return "1" if a callback function for the chnrecv and chnsend opcodes has been set, and "0" otherwise (which means these opcodes do nothing)

## Examples

Here is an example of the getcfg opcode. It uses the file `getcfg.csd` [examples/getcfg.csd].

### Example 355. Example of the getcfg opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# getrow

getrow — Gets a given row from a 2-dimensional array as a vector.

## Description

Gets a given row from a 2-dimensional array. The output is an 1-d array with the contents of the requested row

## Syntax

```
kout[] getrowkin[],krow
```

## Performance

*kout[]* -- output array containing the extracted row. It will be created if it does not exist.

*kin[]* -- input 2-dimensionsal array.

*krow* -- row to be extracted.

## Examples

TODO.

# gogobel

gogobel — Audio output is a tone related to the striking of a cow bell or similar.

## Description

Audio output is a tone related to the striking of a cow bell or similar. The method is a physical model developed from Perry Cook, but re-coded for Csound.

## Syntax

```
ares gogobel kamp, kfreq, ihrd, ipos, imp, kvibf, kvamp, ivfn
```

## Initialization

*ihrd* -- the hardness of the stick used in the strike. A range of 0 to 1 is used. 0.5 is a suitable value.

*ipos* -- where the block is hit, in the range 0 to 1.

*imp* -- a table of the strike impulses. The file *marmstk1.wav* [examples/marmstk1.wav] is a suitable function from measurements and can be loaded with a *GEN01* table. It is also available at <ftp://ftp.cs.bath.ac.uk/pub/dream/documentation/sounds/modelling/>.

*ivfn* -- shape of vibrato, usually a sine table, created by a function.

## Performance

A note is played on a cowbell-like instrument, with the arguments as below.

*kamp* -- Amplitude of note.

*kfreq* -- Frequency of note played.

*kvibf* -- frequency of vibrato in Hertz. Suggested range is 0 to 12

*kvamp* -- amplitude of the vibrato

## Examples

Here is an example of the gogobel opcode. It uses the file *gogobel.csd* [examples/gogobel.csd], and *marmstk1.wav* [examples/marmstk1.wav],

### Example 356. Example of the gogobel opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# goto

goto — Transfer control on every pass.

## Description

Transfer control to *label* on every pass. (Combination of *igoto* and *kgoto*)

## Syntax

```
goto label
```

where *label* is in the same instrument block and is not an expression.

### Note

Using *goto* not as part of an *if* statement (as in: *goto end*), will cause initialization to be skipped on all the code the *goto* jumps over. In performance, leaving some opcodes uninitialized will cause deletion of the note/event. In these cases, using *kgoto* (as in: *kgoto end*) might be preferred."

## Examples

Here is an example of the *goto* opcode. It uses the file *goto.csd* [examples/goto.csd].

### Example 357. Example of the goto opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# grain

grain — Generates granular synthesis textures.

## Description

Generates granular synthesis textures.

## Syntax

```
ares grain xamp, xpitch, xdens, kampoff, kpitchoff, kgdur, igfn, \
      iwfn, imgdur [, igrnd]
```

## Initialization

*igfn* -- The ftable number of the grain waveform. This can be just a sine wave or a sampled sound.

*iwfn* -- Ftable number of the amplitude envelope used for the grains (see also *GEN20*).

*imgdur* -- Maximum grain duration in seconds. This is the biggest value to be assigned to *kgdur*.

*igrnd* (optional) -- if non-zero, turns off grain offset randomness. This means that all grains will begin reading from the beginning of the *igfn* table. If zero (the default), grains will start reading from random *igfn* table positions.

## Performance

*xamp* -- Amplitude of each grain.

*xpitch* -- Grain pitch. To use the original frequency of the input sound, use the formula:

$\text{sndsr} / \text{ftlen}(igfn)$

where *sndsr* is the original sample rate of the *igfn* sound.

*xdens* -- Density of grains measured in grains per second. If this is constant then the output is synchronous granular synthesis, very similar to *fof*. If *xdens* has a random element (like added noise), then the result is more like asynchronous granular synthesis.

*kampoff* -- Maximum amplitude deviation from *xamp*. This means that the maximum amplitude a grain can have is *xamp* + *kampoff* and the minimum is *xamp*. If *kampoff* is set to zero then there is no random amplitude for each grain.

*kpitchoff* -- Maximum pitch deviation from *xpitch* in Hz. Similar to *kampoff*.

*kgdur* -- Grain duration in seconds. The maximum value for this should be declared in *imgdur*. If *kgdur* at any point becomes greater than *imgdur*, it will be truncated to *imgdur*.

The grain generator is based primarily on work and writings of Barry Truax and Curtis Roads.

## Examples

This example generates a texture with gradually shorter grains and wider amp and pitch spread. It uses the file *grain.csd* [examples/grain.csd], and *beats.wav* [examples/beats.wav].

### Example 358. Example of the grain opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# grain2

grain2 — Easy-to-use granular synthesis texture generator.

## Description

Generate granular synthesis textures. *grain2* is simpler to use, but *grain3* offers more control.

## Syntax

```
ares grain2 kcps, kfmd, kgdur, iovrlp, kfn, iwfn [, irpow] \
[, iseed] [, imode]
```

## Initialization

*iovrlp* -- (fixed) number of overlapping grains.

*iwf<sub>n</sub>* -- function table containing window waveform (Use GEN20 to calculate *iwf<sub>n</sub>*).

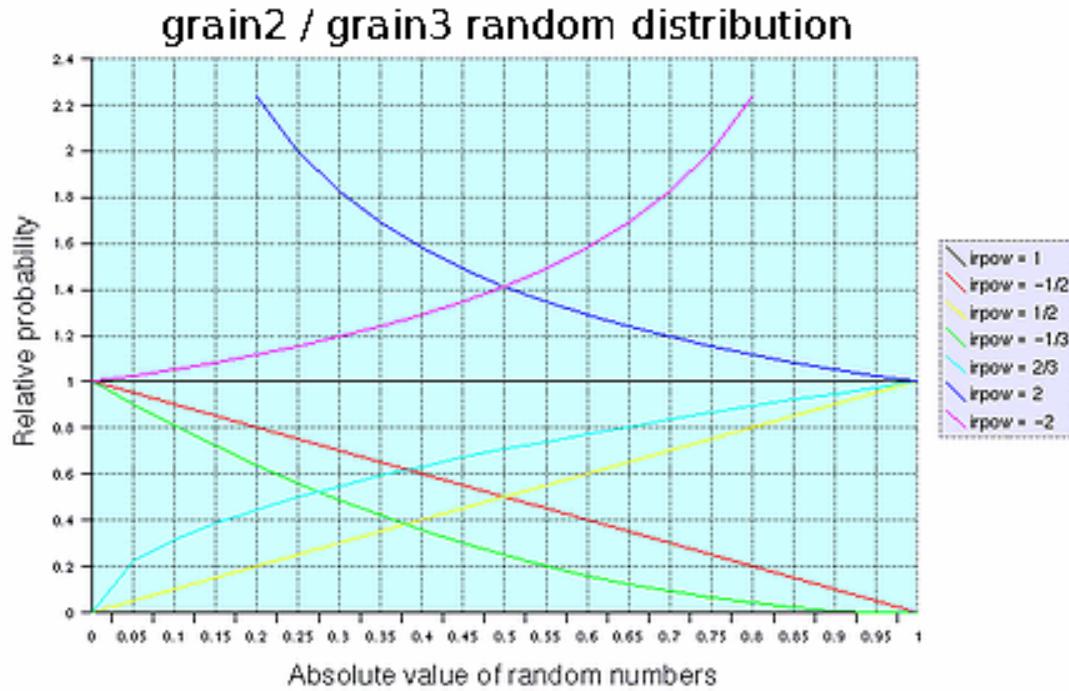

*irpow* (optional, default=0) -- this value controls the distribution of grain frequency variation. If *irpow* is positive, the random distribution (*x* is in the range -1 to 1) is

$\text{abs}(x)^{((1 / \text{irpow}) - 1)}$ ;

for negative *irpow* values, it is

$(1 - \text{abs}(x))^{((-1 / \text{irpow}) - 1)}$

Setting *irpow* to -1, 0, or 1 will result in uniform distribution (this is also faster to calculate). The image below shows some examples for *irpow*. The default value of *irpow* is 0.

A graph of distributions for different values of *irpow*.

*iseed* (optional, default=0) -- seed value for random number generator (positive integer in the range 1 to 2147483646 ( $2^{31} - 2$ )). Zero or negative value seeds from current time (this is also the default).

*imode* (optional default=0) -- sum of the following values:

- 8: interpolate window waveform (slower).
- 4: do not interpolate grain waveform (fast, but lower quality).
- 2: grain frequency is continuously modified by *kcps* and *kfmd* (by default, each grain keeps the frequency it was launched with). This may be slower at high control rates.
- 1: skip initialization.

## Performance

*ares* -- output signal.

*kcps* -- grain frequency in Hz.

*kfmd* -- random variation (bipolar) in grain frequency in Hz.

*kgdur* -- grain duration in seconds. *kgdur* also controls the duration of already active grains (actually the speed at which the window function is read). This behavior does not depend on the *imode* flags.

*kfn* -- function table containing grain waveform. Table number can be changed at k-rate (this is useful to select from a set of band-limited tables generated by GEN30, to avoid aliasing).

## Note

*grain2* internally uses the same random number generator as *rnd31*. So reading *its documentation* is also recommended.

# Examples

Here is an example of the *grain2* opcode. It uses the file *grain2.csd* [examples/grain2.csd].

### Example 359. Example of the grain2 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# grain3

grain3 — Generate granular synthesis textures with more user control.

## Description

Generate granular synthesis textures. *grain2* is simpler to use but *grain3* offers more control.

## Syntax

```
ares grain3 kcps, kphs, kfmd, kpmd, kgdur, kdens, imaxovr, kfn, iwnf, \
      kfrpow, kprpow [, iseed] [, imode]
```

## Initialization

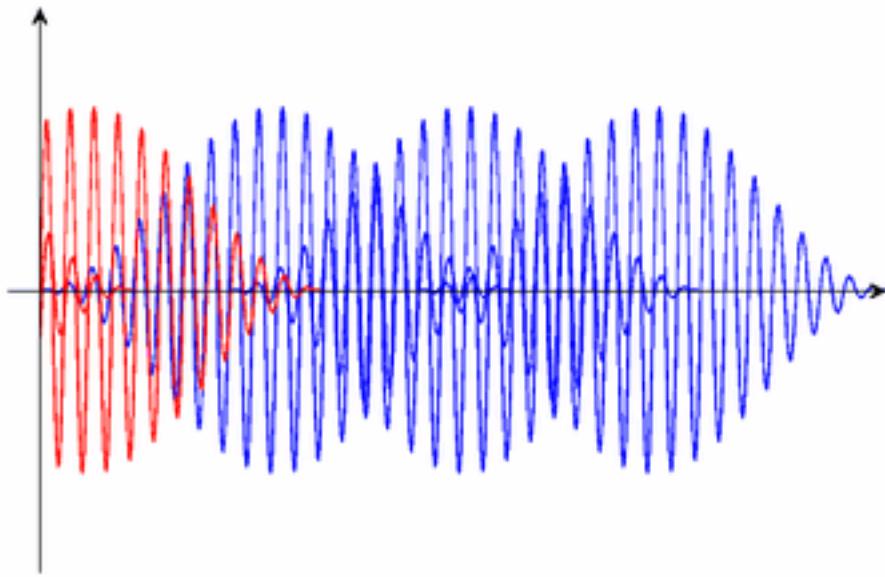

*imaxovr* -- maximum number of overlapping grains. The number of overlaps can be calculated by (*kdens* \* *kgdur*); however, it can be overestimated at no cost in rendering time, and a single overlap uses (depending on system) 16 to 32 bytes of memory.

*iwnf* -- function table containing window waveform (Use GEN20 to calculate *iwnf*).

*iseed* (optional, default=0) -- seed value for random number generator (positive integer in the range 1 to 2147483646 ( $2^{31} - 2$ )). Zero or negative value seeds from current time (this is also the default).

*imode* (optional, default=0) -- sum of the following values:

- 64: synchronize start phase of grains to *kcps*.
- 32: start all grains at integer sample location. This may be faster in some cases, however it also makes the timing of grain envelopes less accurate.
- 16: do not render grains with start time less than zero. (see the image below; this option turns off grains marked with red on the image).
- 8: interpolate window waveform (slower).
- 4: do not interpolate grain waveform (fast, but lower quality).
- 2: grain frequency is continuously modified by *kcps* and *kfmd* (by default, each grain keeps the frequency it was launched with). This may be slower at high control rates. It also controls phase modulation (*kphs*).
- 1: skip initialization.

A diagram showing grains with a start time less than zero in red.

## Performance

*ares* -- output signal.

*kcps* -- grain frequency in Hz.

*kphs* -- grain phase. This is the location in the grain waveform table, expressed as a fraction (between 0 to 1) of the table length.

*kfmd* -- random variation (bipolar) in grain frequency in Hz.

*kpmd* -- random variation (bipolar) in start phase.

*kgdur* -- grain duration in seconds. *kgdur* also controls the duration of already active grains (actually the speed at which the window function is read). This behavior does not depend on the *imode* flags.

*kdens* -- number of grains per second.

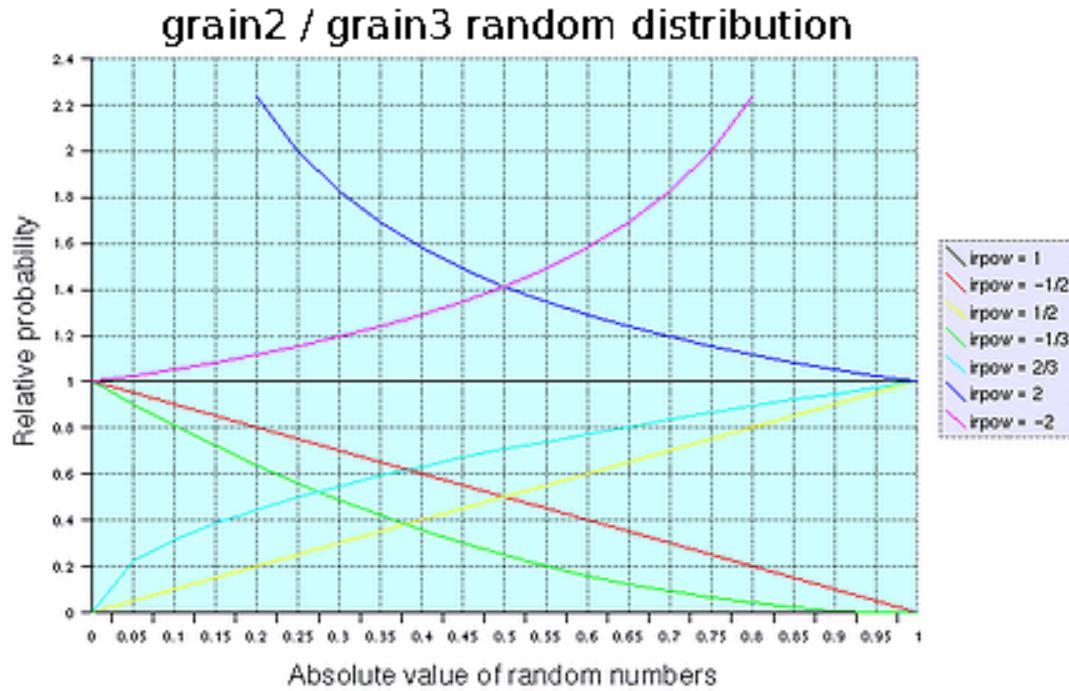

*kfrpow* -- this value controls the distribution of grain frequency variation. If *kfrpow* is positive, the random distribution (*x* is in the range -1 to 1) is

$$\text{abs}(x) ^ ((1 / \text{kfrpow}) - 1)$$

; for negative *kfrpow* values, it is

$$(1 - \text{abs}(x)) ^ ((-1 / \text{kfrpow}) - 1)$$

Setting *kfrpow* to -1, 0, or 1 will result in uniform distribution (this is also faster to calculate). The image below shows some examples for *kfrpow*. The default value of *kfrpow* is 0.

A graph of distributions for different values of *kfrpow*.

*kprpow* -- distribution of random phase variation (see *kfrpow*). Setting *kphs* and *kpmd* to 0.5, and *kprpow* to 0 will emulate *grain2*.

*kfn* -- function table containing grain waveform. Table number can be changed at k-rate (this is useful to select from a set of band-limited tables generated by GEN30, to avoid aliasing).

### Note

*grain3* internally uses the same random number generator as *rnd31*. So reading *its documentation* is also recommended.

## Examples

Here is an example of the *grain3* opcode. It uses the file *grain3.csd* [examples/grain3.csd].

### Example 360. Example of the *grain3* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# granule

*granule* — A more complex granular synthesis texture generator.

## Description

The *granule* unit generator is more complex than *grain*, but does add new possibilities.

*granule* is a Csound unit generator which employs a wavetable as input to produce granularly synthesized audio output. Wavetable data may be generated by any of the GEN subroutines such as *GEN01* which reads an audio data file into a wavetable. This enable a sampled sound to be used as the source for the grains. Up to 128 voices are implemented internally. The maximum number of voices can be increased by redefining the variable MAXVOICE in the grain4.h file. *granule* has a build-in random number generator to handle all the random offset parameters. Thresholding is also implemented to scan the source function table at initialization stage. This facilitates features such as skipping silence passage between sentences.

The characteristics of the synthesis are controlled by 22 parameters. *xamp* is the amplitude of the output and it can be either audio rate or control rate variable.

## Syntax

```
ares granule xamp, ivoice, iratio, imode, ithd, ifn, ipshift, igs skip, \
      igs skip_os, ilength, kgap, igap_os, kgs ize, igs ize_os, iatt, idec \
      [, iseed] [, ipitch1] [, ipitch2] [, ipitch3] [, ipitch4] [, ifnenv]
```

## Initialization

*ivoice* -- number of voices.

*iratio* -- ratio of the speed of the gskip pointer relative to output audio sample rate. eg. 0.5 will be half speed.

*imode* -- +1 grain pointer move forward (same direction of the gskip pointer), -1 backward (oppose direction to the gskip pointer) or 0 for random.

*ithd* -- threshold, if the sampled signal in the wavetable is smaller then *ithd*, it will be skipped.

*ifn* -- function table number of sound source.

*ipshift* -- pitch shift control. If *ipshift* is 0, pitch will be set randomly up and down an octave. If *ipshift* is 1, 2, 3 or 4, up to four different pitches can be set amount the number of voices defined in *ivoice*. The optional parameters *ipitch1*, *ipitch2*, *ipitch3* and *ipitch4* are used to quantify the pitch shifts.

*igs skip* -- initial skip from the beginning of the function table in sec.

*igs skip\_os* -- gskip pointer random offset in sec, 0 will be no offset.

*ilength* -- length of the table to be used starting from *igs skip* in sec.

*igap\_os* -- gap random offset in % of the gap size, 0 gives no offset.

*igs ize\_os* -- grain size random offset in % of grain size, 0 gives no offset.

*iatt* -- attack of the grain envelope in % of grain size.

*idec* -- decade of the grain envelope in % of grain size.

*iseed* (optional, default=0.5) -- seed for the random number generator.

*ipitch1*, *ipitch2*, *ipitch3*, *ipitch4* (optional, default=1) -- pitch shift parameter, used when *ipshift* is set to 1, 2, 3 or 4. Time scaling technique is used in pitch shift with linear interpolation between data points. Default value is 1, the original pitch.

*ifnenv* (optional, default=0) -- function table number to be used to generate the shape of the envelope.

## Performance

*xamp* -- amplitude.

*kgap* -- gap between grains in sec.

*kgsiz*e -- grain size in sec.

## Examples

Here is an example of the granule opcode. It uses the file *granule.csd* [examples/granule.csd], and *mary.wav* [examples/mary.wav].

### Example 361. Example of the granule opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

</CsScore>
```

```
</CsoundSynthesizer>
```

The above example reads a sound file called *mary.wav* into wavetable number 1 with 262,144 samples. It generates 10 seconds of stereo audio output using the wavetable. In the orchestra file, all parameters required to control the synthesis are passed from the score file. A *linseg* function generator is used to generate an envelope with 0.5 second of linear attack and decay. Stereo effect is generated by using different seeds for the two *granule* function calls. In the example, 0.17 is added to p20 before passing into the second *granule* call to ensure that all of the random offset events are different from the first one.

In the score file, the parameters are interpreted as:

| Parameter                                   | Interpreted As  |
|---|---|
| p5 ( <i>ivoice</i> )                        | the number of voices is set to 64   |
| p6 ( <i>iratio</i> )                        | set to 0.5, it scans the wavetable at half of the speed of the audio output rate  |
| p7 ( <i>imode</i> )                         | set to 0, the grain pointer only move forward   |
| p8 ( <i>ithd</i> )                          | set to 0, skipping the thresholding process   |
| p9 ( <i>ifn</i> )                           | set to 1, function table number 1 is used   |
| p10 ( <i>ipshift</i> )                      | set to 4, four different pitches are going to be generated  |
| p11 ( <i>igskip</i> )                       | set to 0 and p12 ( <i>igskip_os</i> ) is set to 0.005, no skipping into the wavetable and a 5 mSec random offset is used            |
| p13 ( <i>ilength</i> )                      | set to 5, 5 seconds of the wavetable is to be used  |
| p14 ( <i>kgap</i> )                         | set to 0.01 and p15 ( <i>igap_os</i> ) is set to 50, 10 mSec gap with 50% random offset is to be used                               |
| p16 ( <i>kgsiz</i> e)                       | set to 0.02 and p17 ( <i>igsize_os</i> ) is set to 50, 20 mSec grain with 50% random offset is used                                 |
| p18 ( <i>iatt</i> ) and p19 ( <i>idec</i> ) | set to 30, 30% of linear attack and decade is applied to the grain  |
| p20 ( <i>iseed</i> )                        | seed for the random number generator is set to 0.39   |
| p21 - p24                                   | pitches set to 1 which is the original pitch, 1.42 which is a 5th up, 0.29 which is a 7th down and finally 2 which is an octave up. |

# guiro

guiro — Semi-physical model of a guiro sound.

## Description

*guiro* is a semi-physical model of a guiro sound. It is one of the PhISEM percussion opcodes. PhISEM (Physically Informed Stochastic Event Modeling) is an algorithmic approach for simulating collisions of multiple independent sound producing objects.

## Syntax

```
ares guiro kamp, idettack [, inum] [, idamp] [, imaxshake] [, ifreq] [, ifreq1]
```

## Initialization

*idettack* -- period of time over which all sound is stopped

*inum* (optional) -- The number of beads, teeth, bells, timbrels, etc. If zero, the default value is 128.

*idamp* (optional) -- the damping factor of the instrument. *Not used.*

*imaxshake* (optional, default=0) -- amount of energy to add back into the system. The value should be in range 0 to 1.

*ifreq* (optional) -- the main resonant frequency. The default value is 2500 Hz.

*ifreq1* (optional) -- the first resonant frequency. Default value here is 4000 Hz

## Performance

*kamp* -- Amplitude of output. Note: As these instruments are stochastic, this is only an approximation.

## Examples

Here is an example of the guiro opcode. It uses the file *guiro.csd* [examples/guiro.csd].

### Example 362. Example of the guiro opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# harmon

harmon — Analyze an audio input and generate harmonizing voices in synchrony.

## Description

Analyze an audio input and generate harmonizing voices in synchrony.

## Syntax

```
ares harmon asig, kestfrq, kmaxvar, kgenfreq1, kgenfreq2, imode, \
      iminfrq, iprd
```

## Initialization

*imode* -- interpreting mode for the generating frequency inputs *kgenfreq1*, *kgenfreq2*. 0: input values are ratios with respect to the audio signal analyzed frequency. 1: input values are the actual requested frequencies in Hz.

*iminfrq* -- the lowest expected frequency (in Hz) of the audio input. This parameter determines how much of the input is saved for the running analysis, and sets a lower bound on the internal pitch tracker.

*iprd* -- period of analysis (in seconds). Since the internal pitch analysis can be time-consuming, the input is typically analyzed only each 20 to 50 milliseconds.

## Performance

*kestfrq* -- estimated frequency of the input.

*kmaxvar* -- the maximum variance (expects a value between 0 and 1).

*kgenfreq1* -- the first generated frequency.

*kgenfreq2* -- the second generated frequency.

This unit is a harmonizer, able to provide up to two additional voices with the same amplitude and spectrum as the input. The input analysis is assisted by two things: an input estimated frequency *kestfrq* (in Hz), and a fractional maximum variance *kmaxvar* about that estimate which serves to limit the size of the search. Once the real input frequency is determined, the most recent pulse shape is used to generate the other voices at their requested frequencies.

The three frequency inputs can be derived in various ways from a score file or MIDI source. The first is the expected pitch, with a variance parameter allowing for inflections or inaccuracies; if the expected pitch is zero the harmonizer will be silent. The second and third pitches control the output frequencies; if either is zero the harmonizer will output only the non-zero request; if both are zero the harmonizer will be silent. When the requested frequency is higher than the input, the process requires additional computation due to overlapped output pulses. This is currently limited for efficiency reasons, with the result that only one voice can be higher than the input at any one time.

This unit is useful for supplying a background chorus effect on demand, or for correcting the pitch of a faulty input vocal. There is essentially no delay between input and output. Output includes only the generated parts, and does not include the input.

## Examples

Here is an example of the harmon opcode. It uses the file *harmon.csd* [examples/harmon.csd].

### Example 363. Example of the harmon opcode.

# harmon2

harmon2 — Analyze an audio input and generate harmonizing voices in synchrony with formants preserved.

## Description

Generate harmonizing voices with formants preserved.

## Syntax

```
ares harmon2 asig, koct, kfrq1, kfrq2, icpsmode, ilowest[, ipolarity]  
  
ares harmon3 asig, koct, kfrq1, \  
      kfrq2, kfrq3, icpsmode, ilowest[, ipolarity]  
  
ares harmon4 asig, koct, kfrq1, \  
      kfrq2, kfrq3, kfrq4, icpsmode, ilowest[, ipolarity]
```

## Initialization

*icpsmode* -- interpreting mode for the generating frequency inputs *kfrq1*, *kfrq2*, *kfrq3* and *kfrq4*: 0: input values are ratios w.r.t. the cps equivalent of *koct*. 1: input values are the actual requested frequencies in cps.

*ilowest* -- lowest value of the *koct* input for which harmonizing voices will be generated.

*ipolarity* -- polarity of *asig* input, 1 = positive glottal pulses, 0 = negative. Default is 1.

## Performance

**Harmon2**, **harmon3** and **harmon4** are high-performance harmonizers, able to provide up to four pitch-shifted copies of the input *asig* with spectral formants preserved. The pitch-shifting algorithm requires an accurate running estimate (*koct*, in decimal oct units) of the pitched content of *asig*, normally gained from an independent pitch tracker such as *specptrk*. The algorithm then isolates the most recent full pulse within *asig*, and uses this to generate the other voices at their required pulse rates.

If the frequency (or ratio) presented to *kfrq1*, *kfrq2*, *kfrq3* or *kfrq4* is zero, then no signal is generated for that voice. If any of them is non-zero, but the *koct* input is below the value *ilowest*, then that voice will output a direct copy of the input *asig*. As a consequence, the data arriving at the k-rate inputs can variously cause the generated voices to be turned on or off, to pass a direct copy of a non-voiced fricative source, or to harmonize the source according to some constructed algorithm. The transition from one mode to another is cross-faded, giving seamless alternating between voiced (harmonized) and non-voiced fricatives during spoken or sung input.

*harmon2*, *harmon3*, *harmon4* are especially matched to the output of *specptrk*. The latter generates pitch data in decimal octave format; it also emits its base value if no pitch is identified (as in fricative noise) and emits zero if the energy falls below a threshold, so that *harmon2*, *harmon3*, *harmon4* can be set to pass the direct signal in both cases. Of course, any other form of pitch estimation could also be used. Since pitch trackers usually incur a slight delay for accurate estimation (for *specptrk* the delay is printed by the *spectrum* unit), it is normal to delay the audio signal by the same amount so that *harmon2*, *harmon3*, *harmon4* can work from a fully concurrent estimate.

## Examples

Here is an example of the harmon2 opcode. It uses the file *harmon.csd* [examples/harmon.csd].

# hdf5read

hdf5read — Read signals and arrays from an hdf5 file.

## Description

*hdf5read* reads  $N$  signals and arrays from a specified hdf5 file.

## Syntax

```
xout1[, xout2, xout3, ..., xoutN] hdf5read ifilename, ivariablename1[, ivariablename2, ivariablename3,
```

## Initialization

*ifilename* -- the hdf5 file's name (in double-quotes).

*ivariablename1[, ivariablename2, ivariablename3, ..., ivariablenameN]* -- the names of the datasets (in double-quotes) to be read from the hdf5 file.

## Performance

*xout1,... xoutN* -- The specified types of variables that the hdf5 datasets are to be read as. Datasets with a rank larger than 1 must be read as arrays, i-rate signals must also be read as i-rate signals. Other than these restrictions datasets may be read as any type of array or signal. When reading has reached the end of a dataset it no longer outputs any new values.

## Examples

Here is a simple example of the hdf5read opcode. It uses the file *hdf5read.csd* [examples/hdf5read.csd].

### Example 366. Example of the hdf5read opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# hdf5write

hdf5write — Write signals and arrays to an hdf5 file.

## Description

*hdf5write* writes  $N$  signals and arrays to a specified hdf5 file.

## Syntax

```
hdf5write ifilename, xout1[, xout2, xout3, ..., xoutN]
```

## Initialization

*filename* -- the hdf5 file's name (in double-quotes). If the file does not exist it will be created.

## Performance

*xout1,... xoutN* -- signals or arrays to be written to the hdf5 file. This opcode accepts i-rate, k-rate, a-rate signals or i-rate, k-rate, a-rate arrays of any dimension. These signals or arrays are written to a dataset within the hdf5 file using the same variable name as in Csound. For example, if the Csound variable is called 'ksignal', then the name of the hdf5 dataset is 'ksignal'. Any number and multiple types of datasets may be written at a time.

## Examples

Here is a simple example of the hdf5write opcode. It uses the file *hdf5write.csd* [examples/hdf5write.csd].

### Example 367. Example of the hdf5write opcode.

# hilbert

`hilbert` — A Hilbert transformer.

## Description

An IIR implementation of a Hilbert transformer.

## Syntax

```
ar1, ar2 hilbert asig
```

## Performance

*asig* -- input signal

*ar1* -- sine output of *asig*

*ar2* -- cosine output of *asig*

*hilbert* is an IIR filter based implementation of a broad-band 90 degree phase difference network. The input to *hilbert* is an audio signal, with a frequency range from 15 Hz to 15 kHz. The outputs of *hilbert* have an identical frequency response to the input (i.e. they sound the same), but the two outputs have a constant phase difference of 90 degrees, plus or minus some small amount of error, throughout the entire frequency range. The outputs are in quadrature.

*hilbert* is useful in the implementation of many digital signal processing techniques that require a signal in phase quadrature. *ar1* corresponds to the cosine output of *hilbert*, while *ar2* corresponds to the sine output. The two outputs have a constant phase difference throughout the audio range that corresponds to the phase relationship between cosine and sine waves.

Internally, *hilbert* is based on two parallel 6th-order allpass filters. Each allpass filter implements a phase lag that increases with frequency; the difference between the phase lags of the parallel allpass filters at any given point is approximately 90 degrees.

Unlike an FIR-based Hilbert transformer, the output of *hilbert* does not have a linear phase response. However, the IIR structure used in *hilbert* is far more efficient to compute, and the nonlinear phase response can be used in the creation of interesting audio effects, as in the second example below.

## Examples

The first example implements frequency shifting, or single sideband amplitude modulation. Frequency shifting is similar to ring modulation, except the upper and lower sidebands are separated into individual outputs. By using only one of the outputs, the input signal can be "detuned," where the harmonic components of the signal are shifted out of harmonic alignment with each other, e.g. a signal with harmonics at 100, 200, 300, 400 and 500 Hz, shifted up by 50 Hz, will have harmonics at 150, 250, 350, 450, and 550 Hz.

Here is the first example of the *hilbert* opcode. It uses the file *hilbert.csd* [examples/hilbert.csd], and *beats.wav* [examples/beats.wav].

### Example 368. Example of the hilbert opcode implementing frequency shifting.

```

The second example is a variation of the first, but with the output being fed back into the input. With very small shift amounts (i.e. between 0 and  $\pm 6$  Hz), the result is a sound that has been described as a “barberpole phaser” or “Shepard tone phase shifter.” Several notches appear in the spectrum, and are constantly swept in the direction opposite that of the shift, producing a filtering effect that is reminiscent of Risset’s “endless glissando”.

Here is the second example of the hilbert opcode. It uses the file *hilbert\_barberpole.csd* [examples/hilbert\_barberpole.csd].

## Technical History

The use of phase-difference networks in frequency shifters was pioneered by Harald Bode<sup>1</sup>. Bode and Bob Moog provide an excellent description of the implementation and use of a frequency shifter in the analog realm in<sup>2</sup>; this would be an excellent first source for those that wish to explore the possibilities of single sideband modulation. Bernie Hutchins provides more applications of the frequency shifter, as well as a detailed technical analysis<sup>3</sup>. A recent paper by Scott Wardle<sup>4</sup> describes a digital implementation of a frequency shifter, as well as some unique applications.

The examples were updated April 2002. Thanks go to Sean Costello for fixing the barberpole example.

# hrtfearly

*hrtfearly* — Generates 3D binaural audio with high-fidelity early reflections in a parametric room using a Phase Truncation algorithm.

## Description

This opcode essentially nests the *hrtfmove* opcode in an image model for a user-definable shoebox-shaped room. A default room can be selected, or advanced room parameters can be used. Room surfaces can be controlled with high and low-frequency absorption coefficients and gain factors of a three-band equaliser.

Although valid as a stand alone opcode, *hrtfearly* is designed to work with *hrtfreverb* to provide spatially accurate, dynamic binaural reverberation. A number of sources can be processed dynamically using a number of *hrtfearly* instances. All can then be processed with one instance of *hrtfreverb*.

## Syntax

```
aleft, aright, irt60low, irt60high, imfp hrtfearly asrc, ksrcx, ksrcy, ksrcz, klstnrx, klstnry, klstnrz  
ifilel, ifiler, idefroom [,ifade, isr, iorder, ithreed, kheadrot, iroomx, iroomy, iroomz, iwall1  
iwalllow, iwallgain1, iwallgain2, iwallgain3, ifloorhigh, ifloorlow, ifloorgain1, ifloorgain2, \  
ifloorgain3, iceilinghigh, iceilinglow, iceilinggain1, iceilinggain2, iceilinggain3]
```

## Initialization

### Initialization

### Initialization

*ifilel* - left HRTF spectral data file.

*ifiler* - right HRTF spectral data file.

#### Note

 Spectral datafiles (based on the MIT HRTF database) are available in 3 different sampling rates: 44.1, 48 and 96 kHz and are labelled accordingly. Input and processing *sr* should match datafile *sr*. Files should be in the current directory or the SADIR (see *Environment Variables*).

#### Note

 HRTF Data files for use with *hrtfmove*, *hrtfmove2*, *hrtfstat*, *hrtfearly*, *hrtfreverb* were updated for Csound 5.15 and later (the code was updated and is more efficient). Old datafiles are now deprecated.

*idefroom* - default room, medium (1: 10\*10\*3), small (2: 3\*4\*3) or large (3: 20\*25\*7). Wall details (high coef, low coef, gain1, gain2, gain3): .3, .1, .75, .95, .9. Floor: .6, .1, .95, .6, .35. Ceiling: .2, .1, 1, 1, 1. If 0 is entered, optional room parameters will be read.

*ifade* - optional, number of processing buffers for phase change crossfade (default 8). Legal range is 1-24. See *hrtfmove*.

*isr* - optional, default 44.1kHz, legal values: 44100, 48000 and 96000.

*iorder* - optional, order of images processed: higher order: more reflections. Defaults to 1, legal range: 0-4.

*ithreed* - optional, process image sources in three dimensions (1) or two (0: default).

*iroomx* - optional, x room size in metres, will be read if no valid default room is entered (all below parameters behave similarly). Minimum room size is 2\*2\*2.

*iroomy* - optional, y room size.

*iroomz* - optional, z room size.

*iwallhigh* - optional, high frequency wall absorption coefficient (all 4 walls are assumed identical). Absorption coefficients will affect reverb time output.

*iwalllow* - optional, low frequency wall absorption coefficient.

*iwallgain1* - optional, gain on filter centred at 250 Hz (all filters have a Q implying 4 octaves).

*iwallgain2* - optional, as above, centred on 1000 Hz.

*iwallgain3* - optional, as above, centred on 4000 Hz.

*ifloorhigh*, *ifloorlow*, *ifloorgain1*, *ifloorgain2*, *ifloorgain3* - as above for floor.

*iceilinghigh*, *iceilinglow*, *iceilinggain1*, *iceilinggain2*, *iceilinggain3* - as above for ceiling.

*ksrcx* source x location, must be 10 cm inside room. Also, near-field HRTFs are not processed, so source will not change spatially within a 45 cm radius of the listener. These restrictions also apply to location parameters below.

*ksrcy* source y location.

*ksrcz* source z location.

*klstnrx*, *klstnry*, *klstnrz* listener location, as above.

*kheadrot* - optional, angular value for head rotation.

*asrc* - Input/source signal.

*irt60low* - suggested low frequency reverb time for later binaural reverb.

*irt60high* - as above, for high frequency.

*imfp* - mean free path of room, to be used with later reverb.

## Examples

Here is an example of the *hrtfearly* and *hrtfreverb* opcodes. It uses the file *hrtfearly.csd* [examples/hrtfearly.csd].

# hrtfmove

hrtfmove — Generates dynamic 3d binaural audio for headphones using magnitude interpolation and phase truncation.

## Description

This opcode takes a source signal and spatialises it in the 3 dimensional space around a listener by convolving the source with stored head related transfer function (HRTF) based filters.

## Syntax

```
aleft, aright hrtfmove asrc, kAz, kElev, ifilel, ifiler [, imode, ifade, isr]
```

## Initialization

### Initialization

*ifilel* -- left HRTF spectral data file

*ifiler* -- right HRTF spectral data file

#### Note

 Spectral datafiles (based on the MIT HRTF database) are available in 3 different sampling rates: 44.1, 48 and 96 khz and are labelled accordingly. Input and processing *sr* should match datafile *sr*. Files should be in the current directory or the SADIR (see *Environment Variables*).

#### Note

 HRTF Data files for use with *hrtfmove*, *hrtfmove2*, *hrtfstat*, *hrtfearly*, *hrtfreverb* were updated for Csound 5.15 and later (the code was updated and is more efficient). Old datafiles are now deprecated.

*imode* -- optional, default 0 for phase truncation, 1 for minimum phase

*ifade* -- optional, number of processing buffers for phase change crossfade (default 8). Legal range is 1-24. A low value is recommended for complex sources (4 or less: a higher value may make the cross-fade audible), a higher value (8 or more: a lower value may make the inconsistency when the filter changes phase values audible) for narrowband sources. Does not effect minimum phase processing.

#### Note

 Ocassionally fades may overlap (when unnaturally fast/complex trajectories are requested). In this case, a warning will be printed. Use a smaller crossfade or slightly change trajectory to avoid any possible inconsistencies that may arise.

*isr* - optional, default 44.1kHz, legal values: 44100, 48000 and 96000.

*kAz* -- azimuth value in degrees. Positive values represent position on the right, negative values are positions on the left.

*kElev* -- elevation value in degrees. Positive values represent position above horizontal, negative values are positions below horizontal (min -40).

Artifact-free user-defined trajectories are made possible using an interpolation algorithm based on spectral magnitude interpolation and phase truncation. Crossfades are implemented to minimise/eliminate any inconsistencies caused by updating phase values. These crossfades are performed over a user definable number of convolution processing buffers. Complex sources may only need to crossfade over 1 buffer; narrow band sources may need several. The opcode also offers minimum phase based processing, a more traditional and complex method. In this mode, the hrtf filters used are reduced to minimum phase representations and the interpolation process then uses the relationship between minimum phase magnitude and phase spectra. Interaural time difference, which is inherent to the phase truncation process, is reintroduced in the minimum phase process using variable delay lines.

## Examples

Here is an example of the hrtfmove opcode. It uses the file *hrtfmove.csd* [examples/hrtfmove.csd].

# hrtfmove2

**hrtfmove2** — Generates dynamic 3d binaural audio for headphones using a Woodworth based spherical head model with improved low frequency phase accuracy.

## Description

This opcode takes a source signal and spatialises it in the 3 dimensional space around a listener using head related transfer function (HRTF) based filters.

## Syntax

```
aleft, aright hrtfmove2 asrc, kAz, kElev, ifilel, ifiler [,ioverlap, iradius, isr]
```

## Initialization

*ifilel* -- left HRTF spectral data file

*ifiler* -- right HRTF spectral data file

### Note

Spectral datafiles (based on the MIT HRTF database) are available in 3 different sampling rates: 44.1, 48 and 96 khz and are labelled accordingly. Input and processing *sr* should match datafile *sr*. Files should be in the current directory or the SADIR (see *Environment Variables*).

### Note

HRTF Data files for use with *hrtfmove*, *hrtfmove2*, *hrtfstat*, *hrtfearly*, *hrtfreverb* were updated for Csound 5.15 and later (the code was updated and is more efficient). Old datafiles are now deprecated.

*ioverlap* -- optional, number of overlaps for STFT processing (default 4). See STFT section of manual.

*iradius* -- optional, head radius used for phase spectra calculation in centimeters (default 9.0)

*isr* - optional, default 44.1kHz, legal values: 44100, 48000 and 96000.

## Performance

*asrc* -- Input/source signal.

*kAz* -- azimuth value in degrees. Positive values represent position on the right, negative values are positions on the left.

*kElev* -- elevation value in degrees. Positive values represent position above horizontal, negative values are positions below horizontal (min -40).

Artifact-free user-defined trajectories are made possible using an interpolation algorithm based on spectral magnitude interpolation and a derived phase spectrum based on the Woodworth spherical head mod-

el. Accuracy is increased for the data set provided by extracting and applying a frequency dependent scaling factor to the phase spectra, leading to a more precise low frequency interaural time difference. Users can control head radius for the phase derivation, allowing a crude level of individualisation. The dynamic source version of the opcode uses a Short Time Fourier Transform algorithm to avoid artefacts caused by derived phase spectra changes. STFT processing means this opcode is more computationally intensive than *hrtfmove* using phase truncation, but phase is constantly updated by *hrtfmove2*.

## Examples

Here is an example of the *hrtfmove2* opcode. It uses the file *hrtfmove2.csd* [examples/hrtfmove2.csd].

# hrtfreverb

**hrtfreverb** — A binaural, dynamic FDN based diffuse-field reverberator. The opcode works independently as an efficient, flexible reverberator.

## Description

A frequency-dependent, efficient reverberant field is created based on low and high frequency desired reverb times. The opcode is designed to work with *hrtfearly*, ideally using its outputs as inputs. However, *hrtfreverb* can be used as a standalone tool. Stability is enforced.

It is, however, designed for use with *hrtfearly* to provide spatially accurate reverberation with user definable source trajectories. Accurate interaural coherence is also provided.

## Syntax

```
aleft, aright, idel hrtfreverb asrc, ilowrt60, ihighrt60, ifilel, ifiler [,isr, imfp, iorder]
```

## Initialization

### Initialization

### Initialization

*ilowrt60* - low frequency reverb time.

*ihighrt60* - high frequency reverb time.

*ifilel* - left HRTF spectral data file.

*ifiler* - right HRTF spectral data file.

#### Note

 Spectral datafiles (based on the MIT HRTF database) are available in 3 different sampling rates: 44.1, 48 and 96 kHz and are labelled accordingly. Input and processing *sr* should match datafile *sr*. Files should be in the current directory or the SADIR (see *Environment Variables*).

#### Note

 HRTF Data files for use with *hrtfmove*, *hrtfmove2*, *hrtfstat*, *hrtfreverb*, *hrtfreverb* were updated for Csound 5.15 and later (the code was updated and is more efficient). Old datafiles are now deprecated.

*isr* - optional, default 44.1kHz, legal values: 44100, 48000 and 96000.

*imfp* - optional, mean free path, defaults to that of a medium room. If used with *hrtfearly*, the mean free path of the room can be used to calculate the appropriate delay for the later reverb. Legal range: the mean free path of the smallest room allowed by *hrtfearly* (0.003876) 1.

*iorder* - optional, order of early reflection processing. If used with *hrtfearly*, the order of early reflections can be used to calculate the appropriate delay on the later reverb.

*asrc* - Input/source signal.

*idel* - if used with *hrtfearly*, the appropriate delay for the later reverb, based on the room and order of processing.

## Example

See the *hrtfearly* manual page for a simple example of the *hrtfearly* and *hrtfreverb* opcodes.

# hrtfstat

hrtfstat — Generates static 3d binaural audio for headphones using a Woodworth based spherical head model with improved low frequency phase accuracy.

## Description

This opcode takes a source signal and spatialises it in the 3 dimensional space around a listener using head related transfer function (HRTF) based filters. It produces a static output (azimuth and elevation parameters are i-rate), because a static source allows much more efficient processing than *hrtfmove* and *hrtfmove2*.

## Syntax

```
aleft, aright hrtfstat asrc, iAz, iElev, ifilel, ifiler [,iradius, isr]
```

## Initialization

*iAz* -- azimuth value in degrees. Positive values represent position on the right, negative values are positions on the left.

*iElev* -- elevation value in degrees. Positive values represent position above horizontal, negative values are positions below horizontal (min -40).

*ifilel* -- left HRTF spectral data file

*ifiler* -- right HRTF spectral data file

### Note

 Spectral datafiles (based on the MIT HRTF database) are available in 3 different sampling rates: 44.1, 48 and 96 khz and are labelled accordingly. Input and processing sr should match datafile sr. Files should be in the current directory or the SADIR (see *Environment Variables*).

### Note

 HRTF Data files for use with *hrtfmove*, *hrtfmove2*, *hrtfstat*, *hrtfearly*, *hrtfreverb* were updated for Csound 5.15 and later (the code was updated and is more efficient). Old datafiles are now deprecated.

*iradius* -- optional, head radius used for phase spectra calculation in centimeters (default 9.0)

*isr* - optional (default 44.1kHz). Legal values are 44100, 48000 and 96000.

## Performance

Artifact-free user-defined static spatialisation is made possible using an interpolation algorithm based on spectral magnitude interpolation and a derived phase based on the Woodworth spherical head model.

Accuracy is increased for the data set provided by extracting and applying a frequency dependent scaling factor to the phase spectra, leading to a more precise low frequency interaural time difference. Users can control head radius for the phase derivation, allowing a crude level of individualisation. The static source version of the opcode uses overlap add convolution (it does not need STFT processing, see *hrtfmove2*), and is thus considerably more efficient than *hrtfmove2* or *hrtfmove*, but cannot generate moving sources.

## Examples

Here is an example of the *hrtfstat* opcode. It uses the file *hrtfstat.csd* [examples/hrtfstat.csd].

### Example 373. Example of the *hrtfstat* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# hsboscil

hsboscil — An oscillator which takes tonality and brightness as arguments.

## Description

An oscillator which takes tonality and brightness as arguments, relative to a base frequency.

## Syntax

```
ares hsboscil kamp, ktone, kbrite, ibasfreq, iwfn, ioctfn \
      [, ioctcnt] [, iphs]
```

## Initialization

*ibasfreq* -- base frequency to which tonality and brightness are relative

*iwfn* -- function table of the waveform, usually a sine

*ioctfn* -- function table used for weighting the octaves, usually something like:

**f1** 0 1024 -19 1 0.5 270 0.5

*ioctcnt* (optional) -- number of octaves used for brightness blending. Must be in the range 2 to 10. Default is 3.

*iphs* (optional, default=0) -- initial phase of the oscillator. If *iphs* = -1, initialization is skipped.

## Performance

*kamp* -- amplitude of note

*ktone* -- cyclic tonality parameter relative to *ibasfreq* in logarithmic octave, range 0 to 1, values > 1 can be used, and are internally reduced to *frac(ktone)*.

*kbrite* -- brightness parameter relative to *ibasfreq*, achieved by weighting *ioctcnt* octaves. It is scaled in such a way, that a value of 0 corresponds to the original value of *ibasfreq*, 1 corresponds to one octave above *ibasfreq*, -2 corresponds to two octaves below *ibasfreq*, etc. *kbrite* may be fractional.

*hsboscil* takes tonality and brightness as arguments, relative to a base frequency (*ibasfreq*). Tonality is a cyclic parameter in the logarithmic octave, brightness is realized by mixing multiple weighted octaves. It is useful when tone space is understood in a concept of polar coordinates.

Making *ktone* a line, and *kbrite* a constant, produces Risset's glissando.

Oscillator table *iwfn* is always read interpolated. Performance time requires about *ioctcnt \* oscili*.

## Examples

Here is an example of the hsboscil opcode. It uses the file *hsboscil.csd* [examples/hsboscil.csd].

# **hvs1**

**hvs1** — Allows one-dimensional Hyper Vectorial Synthesis (HVS) controlled by externally-updated k-variables.

## **Description**

*hvs1* allows one-dimensional Hyper Vectorial Synthesis (HVS) controlled by externally-updated k-variables.

## **Syntax**

```
hvs1 kx, inumParms, inumPointsX, iOutTab, iPositionsTab, iSnapTab [, iConfigTab]
```

## **Initialization**

*inumParms* - number of parameters controlled by the HVS. Each HVS snapshot is made up of *inumParms* elements.

*inumPointsX* - number of points that each dimension of the HVS cube (or square in case of two-dimensional HVS; or line in case of one-dimensional HVS) is made up.

*iOutTab* - number of the table receiving the set of output-parameter instant values of the HVS. The total amount of parameters is defined by the *inumParms* argument.

*iPositionsTab* – a table filled with the individual positions of snapshots in the HVS matrix (see below for more information).

*iSnapTab* – a table filled with all the snapshots. Each snapshot is made up of a set of parameter values. The amount of elements contained in each snapshots is specified by the *inumParms* argument. The set of elements of each snapshot follows (and is adjacent) to the previous one in this table. So the total size of this table should be  $\geq$  to *inumParms* multiplied the number of snapshots you intend to store for the HVS.

*iConfigTab* – (optional) a table containing the behavior of the HVS for each parameter. If the value of *iConfigTab* is zero (default), this argument is ignored, meaning that each parameter is treated with linear interpolation by the HVS. If *iConfigTab* is different than zero, then it must refer to an existing table whose contents are in its turn referring to a particolar kind of interpolation. In this table, a value of -1 indicates that corresponding parameter is leaved unchanged (ignored) by the HVS; a value of zero indicates that corresponding parameter is treated with linear-interpolation; each other values must be integer numbers indicating an existing table filled with a shape which will determine the kind of special interpolation to be used (table-based interpolation).

## **Performance**

*kx* - these are externally-modified variables which controls the motion of the pointer in the HVS matrix cube (or square or line in case of HVS matrices made up of less than 3 dimensions). The range of these input arguments must be 0 to 1.

Hyper Vectorial Synthesis is a technique that allows control of a huge set of parameters by using a simple and global approach. The key concepts of the HVS are:

The set of HVS parameters, whose amount is fixed and defined by the *inumParms* argument. During the

HVS performance, all these parameters are variant and can be applied to any sound synthesis technique, as well as to any global control for algorithmic composition and any other kind of level. The user must previously define several sets of fixed values for each HVS parameter, each set corresponding to a determinate synthesis configuration. Each set of values is called snapshot, and can be considered as the coordinates of a bound of a multi-dimensional space. The HVS consists on moving a point in this multi-dimensional space (by using a special motion pointer, see below), according and inside the bounds defined by the snapshots. You can fix any amount of HVS parameters (each parameter being a dimension of the multi-dimensional space), even a huge number, the limit only depends on the processing power (and the memory) of your computer and on the complexity of the sound-synthesis you will use.

The HVS cube (or square or line). This is the matrix (of 3, 2 or 1 dimensions, according to the hvs opcode you intend to use) of “mainstays” (or pivot) points of HVS. The total amount of pivot-points depends on the value of the *inumPointsX*, *inumPointsY* and *inumPointsZ* arguments. In the case of a 3-dimensional HVS matrix you can define, for instance, 3 points for the X dimension, 5 for the Y dimension and 2 for the Z dimension. In this case, the total number of pivot-points is  $3 * 5 * 2 = 30$ . With this set of pivot points, the cube Is divided into smaller cubed zones each one bounded by eight nearby points. Each point is numbered. The numeral order of these points is established in the following way: number zero is the first point, number 1 the second and so on. Assuming you are using a 3-dimensional HVS cube having the number of points above mentioned (i.e. 3, 5 and 2 respectively for the X, Y and Z axis), the first point (point zero) is the upper-left-front vertex of the cube, by facing the XY plane of the cube. The second point is the middle point of the upper front edge of the cube and so on. You can refer to the figure below in order to understand how the numeral order of the pivot-points proceeds:

For the 2-dimensional HVS, it is the same, by only omitting the rear cube face, so each zone is bounded by 4 pivot-points instead of 8. For the 1-dimensional HVS, the whole thing is even simpler because it is a line with the pivot-points proceeding from left to right. Each point is coupled with a snapshot.

Snapshot order, as stored into the *iSnapTab*, can or cannot follow the order of the pivot-points numbers. In fact it is possible to alter this order by means the *iPositionsTab*, a table that remaps the position of each snapshot in relation to the pivot points. The *iPositionsTab* is made up of the positions of the snapshots (contained in the *iSnapTab*) in the two-dimensional grid. Each subsequent element is actually a pointer representing the position in the *iSnapTab*. For example, in a 2-dimensional HVS matrix such as the following (in this case having *inumPointsX* = 3 and *inumPointsY* = 5:

**Table 9.**

|   |   |   |
|---|---|---|
| 5 | 7 | 1 |
| 3 | 4 | 9 |
| 6 | 2 | 0 |
| 4 | 1 | 3 |
| 8 | 2 | 7 |

These numbers (to be stored in the *iSnapTab* table by using, for instance, the GEN02 function generator) represents the snapshot position within the grid (in this case a 3x5 matrix). So, the first element 5, has index zero and represents the 6th (element zero is the first) snapshot contained in the *iSnapTab*, the second element 7 represents the 8th element of *iSnapTab* and so on. Summing up, the vertices of each zone (a cubed zone is delimited by 8 vertices; a squared zone by 4 vertices and a linear zone by 2 points) are coupled with a determinate snapshot, whose number is remapped by the *iSnapTab*.

Output values of the HVS are influenced by the motion pointer, a point whose position, in the HVS cube (or square or segment) is determined by the *kx*, *ky* and *kz* arguments. The values of these arguments, which must be in the 0 to 1 range, are externally set by the user. The output values, whose amount is equal to the *inumParms* argument, are stored in the *iOutTab*, a table that must be already allocated by the user, and must be at least *inumParms* size. In what way the motion pointer influences the output? Well, when the motion pointer falls in a determinate cubed zone, delimited, for instance, by 8 vertices

(or pivot points), we assume that each vertex has associated a different snapshot (i.e. a set of *iNumParms* values), well, the output will be the weighted average value of the 8 vertices, calculated according on the distance of the motion pointer from each of the 8 vertices. In the case of a default behavior, when the *iConfigTab* argument is not set, the exact output is calculated by using linear interpolation which is applied to each different parameter of the HVS. Anyway, it is possible to influence this behavior by setting the *iConfigTab* argument to a number of a table whose contents can affect one or more HVS parameters. The *iConfigTab* table elements are associated to each HVS parameter and their values affect the HVS output in the following way:

- If *iConfigTab* is equal to -1, corresponding output is skipped, i.e. the element is not calculated, leaving corresponding element value in the *iOutTab* unchanged;
- If *iConfigTab* is equal to zero, then the normal HVS output is calculated (by using weighted average of the nearest vertex of current zone where it falls the motion pointer);
- If *iConfigTab* element is equal to an integer number > zero, then the contents of a table having that number is used as a shape of a table-based interpolation.

## Examples

Here is an example of the `hvs1` opcode. It uses the file `hvs1.csd` [examples/hvs1.csd].

### Example 377. Example of the `hvs1` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# **hvs2**

**hvs2** — Allows two-dimensional Hyper Vectorial Synthesis (HVS) controlled by externally-updated k-variables.

## **Description**

*hvs2* allows two-dimensional Hyper Vectorial Synthesis (HVS) controlled by externally-updated k-variables.

## **Syntax**

```
hvs2 kx, ky, inumParms, inumPointsX, inumPointsY, iOutTab, iPositionsTab, iSnapTab [, iConfigTab]
```

## **Initialization**

*inumParms* - number of parameters controlled by the HVS. Each HVS snapshot is made up of *inumParms* elements.

*inumPointsX*, *inumPointsY* - number of points that each dimension of the HVS cube (or square in case of two-dimensional HVS; or line in case of one-dimensional HVS) is made up.

*iOutTab* - number of the table receiving the set of output-parameter instant values of the HVS. The total amount of parameters is defined by the *inumParms* argument.

*iPositionsTab* – a table filled with the individual positions of snapshots in the HVS matrix (see below for more information).

*iSnapTab* – a table filled with all the snapshots. Each snapshot is made up of a set of parameter values. The amount of elements contained in each snapshots is specified by the *inumParms* argument. The set of elements of each snapshot follows (and is adjacent) to the previous one in this table. So the total size of this table should be  $\geq$  to *inumParms* multiplied the number of snapshots you intend to store for the HVS.

*iConfigTab* – (optional) a table containing the behavior of the HVS for each parameter. If the value of *iConfigTab* is zero (default), this argument is ignored, meaning that each parameter is treated with linear interpolation by the HVS. If *iConfigTab* is different than zero, then it must refer to an existing table whose contents are in its turn referring to a particolar kind of interpolation. In this table, a value of -1 indicates that corresponding parameter is leaved unchanged (ignored) by the HVS; a value of zero indicates that corresponding parameter is treated with linear-interpolation; each other values must be integer numbers indicating an existing table filled with a shape which will determine the kind of special interpolation to be used (table-based interpolation).

## **Performance**

*kx*, *ky* - these are externally-modified variables which controls the motion of the pointer in the HVS matrix cube (or square or line in case of HVS matrices made up of less than 3 dimensions). The range of these input arguments must be 0 to 1.

Hyper Vectorial Synthesis is a technique that allows control of a huge set of parameters by using a simple and global approach. The key concepts of the HVS are:

The set of HVS parameters, whose amount is fixed and defined by the *inumParms* argument. During the

HVS performance, all these parameters are variant and can be applied to any sound synthesis technique, as well as to any global control for algorithmic composition and any other kind of level. The user must previously define several sets of fixed values for each HVS parameter, each set corresponding to a determinate synthesis configuration. Each set of values is called snapshot, and can be considered as the coordinates of a bound of a multi-dimensional space. The HVS consists on moving a point in this multi-dimensional space (by using a special motion pointer, see below), according and inside the bounds defined by the snapshots. You can fix any amount of HVS parameters (each parameter being a dimension of the multi-dimensional space), even a huge number, the limit only depends on the processing power (and the memory) of your computer and on the complexity of the sound-synthesis you will use.

The HVS cube (or square or line). This is the matrix (of 3, 2 or 1 dimensions, according to the hvs opcode you intend to use) of “mainstays” (or pivot) points of HVS. The total amount of pivot-points depends on the value of the *inumPointsX*, *inumPointsY* and *inumPointsZ* arguments. In the case of a 3-dimensional HVS matrix you can define, for instance, 3 points for the X dimension, 5 for the Y dimension and 2 for the Z dimension. In this case, the total number of pivot-points is  $3 * 5 * 2 = 30$ . With this set of pivot points, the cube Is divided into smaller cubed zones each one bounded by eight nearby points. Each point is numbered. The numeral order of these points is established in the following way: number zero is the first point, number 1 the second and so on. Assuming you are using a 3-dimensional HVS cube having the number of points above mentioned (i.e. 3, 5 and 2 respectively for the X, Y and Z axis), the first point (point zero) is the upper-left-front vertex of the cube, by facing the XY plane of the cube. The second point is the middle point of the upper front edge of the cube and so on. You can refer to the figure below in order to understand how the numeral order of the pivot-points proceeds:

For the 2-dimensional HVS, it is the same, by only omitting the rear cube face, so each zone is bounded by 4 pivot-points instead of 8. For the 1-dimensional HVS, the whole thing is even simpler because it is a line with the pivot-points proceeding from left to right. Each point is coupled with a snapshot.

Snapshot order, as stored into the *iSnapTab*, can or cannot follow the order of the pivot-points numbers. In fact it is possible to alter this order by means the *iPositionsTab*, a table that remaps the position of each snapshot in relation to the pivot points. The *iPositionsTab* is made up of the positions of the snapshots (contained in the *iSnapTab*) in the two-dimensional grid. Each subsequent element is actually a pointer representing the position in the *iSnapTab*. For example, in a 2-dimensional HVS matrix such as the following (in this case having *inumPointsX* = 3 and *inumPointsY* = 5:

**Table 10.**

|   |   |   |
|---|---|---|
| 5 | 7 | 1 |
| 3 | 4 | 9 |
| 6 | 2 | 0 |
| 4 | 1 | 3 |
| 8 | 2 | 7 |

These numbers (to be stored in the *iSnapTab* table by using, for instance, the GEN02 function generator) represents the snapshot position within the grid (in this case a 3x5 matrix). So, the first element 5, has index zero and represents the 6th (element zero is the first) snapshot contained in the *iSnapTab*, the second element 7 represents the 8th element of *iSnapTab* and so on. Summing up, the vertices of each zone (a cubed zone is delimited by 8 vertices; a squared zone by 4 vertices and a linear zone by 2 points) are coupled with a determinate snapshot, whose number is remapped by the *iSnapTab*.

Output values of the HVS are influenced by the motion pointer, a point whose position, in the HVS cube (or square or segment) is determined by the *kx*, *ky* and *kz* arguments. The values of these arguments, which must be in the 0 to 1 range, are externally set by the user. The output values, whose amount is equal to the *inumParms* argument, are stored in the *iOutTab*, a table that must be already allocated by the user, and must be at least *inumParms* size. In what way the motion pointer influences the output? Well, when the motion pointer falls in a determinate cubed zone, delimited, for instance, by 8 vertices

(or pivot points), we assume that each vertex has associated a different snapshot (i.e. a set of *inumParms* values), well, the output will be the weighted average value of the 8 vertices, calculated according on the distance of the motion pointer from each of the 8 vertices. In the case of a default behavior, when the *iConfigTab* argument is not set, the exact output is calculated by using linear interpolation which is applied to each different parameter of the HVS. Anyway, it is possible to influence this behavior by setting the *iConfigTab* argument to a number of a table whose contents can affect one or more HVS parameters. The *iConfigTab* table elements are associated to each HVS parameter and their values affect the HVS output in the following way:

- If *iConfigTab* is equal to -1, corresponding output is skipped, i.e. the element is not calculated, leaving corresponding element value in the *iOutTab* unchanged;
- If *iConfigTab* is equal to zero, then the normal HVS output is calculated (by using weighted average of the nearest vertex of current zone where it falls the motion pointer);
- If *iConfigTab* element is equal to an integer number > zero, then the contents of a table having that number is used as a shape of a table-based interpolation.

```

## **Initialization**

*inumParms* - number of parameters controlled by the HVS. Each HVS snapshot is made up of *inumParms* elements.

*inumPointsX*, *inumPointsY*, *inumPointsZ* - number of points that each dimension of the HVS cube (or square in case of two-dimensional HVS; or line in case of one-dimensional HVS) is made up.

*iOutTab* - number of the table receiving the set of output-parameter instant values of the HVS. The total amount of parameters is defined by the *inumParms* argument.

*iPositionsTab* – a table filled with the individual positions of snapshots in the HVS matrix (see below for more information).

*iSnapTab* – a table filled with all the snapshots. Each snapshot is made up of a set of parameter values. The amount of elements contained in each snapshots is specified by the *inumParms* argument. The set of elements of each snapshot follows (and is adjacent) to the previous one in this table. So the total size of this table should be  $\geq$  to *inumParms* multiplied the number of snapshots you intend to store for the HVS.

*iConfigTab* – (optional) a table containing the behavior of the HVS for each parameter. If the value of *iConfigTab* is zero (default), this argument is ignored, meaning that each parameter is treated with linear interpolation by the HVS. If *iConfigTab* is different than zero, then it must refer to an existing table whose contents are in its turn referring to a particolar kind of interpolation. In this table, a value of -1 indicates that corresponding parameter is leaved unchanged (ignored) by the HVS; a value of zero indicates that corresponding parameter is treated with linear-interpolation; each other values must be integer numbers indicating an existing table filled with a shape which will determine the kind of special interpolation to be used (table-based interpolation).

## **Performance**

*kx*, *ky*, *kz* - these are externally-modified variables which controls the motion of the pointer in the HVS matrix cube (or square or line in case of HVS matrices made up of less than 3 dimensions). The range of these input arguments must be 0 to 1.

Hyper Vectorial Synthesis is a technique that allows control of a huge set of parameters by using a simple and global approach. The key concepts of the HVS are:

The set of HVS parameters, whose amount is fixed and defined by the *inumParms* argument. During the

HVS performance, all these parameters are variant and can be applied to any sound synthesis technique, as well as to any global control for algorithmic composition and any other kind of level. The user must previously define several sets of fixed values for each HVS parameter, each set corresponding to a determinate synthesis configuration. Each set of values is called snapshot, and can be considered as the coordinates of a bound of a multi-dimensional space. The HVS consists on moving a point in this multi-dimensional space (by using a special motion pointer, see below), according and inside the bounds defined by the snapshots. You can fix any amount of HVS parameters (each parameter being a dimension of the multi-dimensional space), even a huge number, the limit only depends on the processing power (and the memory) of your computer and on the complexity of the sound-synthesis you will use.

The HVS cube (or square or line). This is the matrix (of 3, 2 or 1 dimensions, according to the hvs opcode you intend to use) of “mainstays” (or pivot) points of HVS. The total amount of pivot-points depends on the value of the *inumPointsX*, *inumPointsY* and *inumPointsZ* arguments. In the case of a 3-dimensional HVS matrix you can define, for instance, 3 points for the X dimension, 5 for the Y dimension and 2 for the Z dimension. In this case, the total number of pivot-points is  $3 * 5 * 2 = 30$ . With this set of pivot points, the cube Is divided into smaller cubed zones each one bounded by eight nearby points. Each point is numbered. The numeral order of these points is established in the following way: number zero is the first point, number 1 the second and so on. Assuming you are using a 3-dimensional HVS cube having the number of points above mentioned (i.e. 3, 5 and 2 respectively for the X, Y and Z axis), the first point (point zero) is the upper-left-front vertex of the cube, by facing the XY plane of the cube. The second point is the middle point of the upper front edge of the cube and so on. You can refer to the figure below in order to understand how the numeral order of the pivot-points proceeds:

For the 2-dimensional HVS, it is the same, by only omitting the rear cube face, so each zone is bounded by 4 pivot-points instead of 8. For the 1-dimensional HVS, the whole thing is even simpler because it is a line with the pivot-points proceeding from left to right. Each point is coupled with a snapshot.

Snapshot order, as stored into the *iSnapTab*, can or cannot follow the order of the pivot-points numbers. In fact it is possible to alter this order by means the *iPositionsTab*, a table that remaps the position of each snapshot in relation to the pivot points. The *iPositionsTab* is made up of the positions of the snapshots (contained in the *iSnapTab*) in the two-dimensional grid. Each subsequent element is actually a pointer representing the position in the *iSnapTab*. For example, in a 2-dimensional HVS matrix such as the following (in this case having *inumPointsX* = 3 and *inumPointsY* = 5:

**Table 11.**

|   |   |   |
|---|---|---|
| 5 | 7 | 1 |
| 3 | 4 | 9 |
| 6 | 2 | 0 |
| 4 | 1 | 3 |
| 8 | 2 | 7 |

These numbers (to be stored in the *iSnapTab* table by using, for instance, the GEN02 function generator) represents the snapshot position within the grid (in this case a 3x5 matrix). So, the first element 5, has index zero and represents the 6th (element zero is the first) snapshot contained in the *iSnapTab*, the second element 7 represents the 8th element of *iSnapTab* and so on. Summing up, the vertices of each zone (a cubed zone is delimited by 8 vertices; a squared zone by 4 vertices and a linear zone by 2 points) are coupled with a determinate snapshot, whose number is remapped by the *iSnapTab*.

Output values of the HVS are influenced by the motion pointer, a point whose position, in the HVS cube (or square or segment) is determined by the *kx*, *ky* and *kz* arguments. The values of these arguments, which must be in the 0 to 1 range, are externally set by the user. The output values, whose amount is equal to the *inumParms* argument, are stored in the *iOutTab*, a table that must be already allocated by the user, and must be at least *inumParms* size. In what way the motion pointer influences the output? Well, when the motion pointer falls in a determinate cubed zone, delimited, for instance, by 8 vertices

(or pivot points), we assume that each vertex has associated a different snapshot (i.e. a set of *inumParms* values), well, the output will be the weighted average value of the 8 vertices, calculated according on the distance of the motion pointer from each of the 8 vertices. In the case of a default behavior, when the *iConfigTab* argument is not set, the exact output is calculated by using linear interpolation which is applied to each different parameter of the HVS. Anyway, it is possible to influence this behavior by setting the *iConfigTab* argument to a number of a table whose contents can affect one or more HVS parameters. The *iConfigTab* table elements are associated to each HVS parameter and their values affect the HVS output in the following way:

- If *iConfigTab* is equal to -1, corresponding output is skipped, i.e. the element is not calculated, leaving corresponding element value in the *iOutTab* unchanged;
- If *iConfigTab* is equal to zero, then the normal HVS output is calculated (by using weighted average of the nearest vertex of current zone where it falls the motion pointer);
- If *iConfigTab* element is equal to an integer number > zero, then the contents of a table having that number is used as a shape of a table-based interpolation.

New in version 5.06

**i**

**i** — Returns an init-type equivalent of a k-rate argument, or directly returns an i-rate argument.

## Description

Returns an init-type equivalent of a k-rate argument, or directly returns an i-rate argument.

## Syntax

`i(x) (control-rate or init-rate arg)`

Value converters perform arithmetic translation from units of one kind to units of another. The result can then be a term in a further expression.

### Note

Using `i()` with a k-rate expression argument is not recommended, and can produce unexpected results.

## See Also

`a, k, abs, exp, frac, int, log, log10, sqrt`

More information on this opcode: <http://www.csoundjournal.com/issue10/CsoundRates.html> , written by Andrés Cabrera

## Credits

i-rate arg version of function new since 5.14

# if

**if** — Branches conditionally at initialization or during performance time.

## Description

**if...igoto** -- conditional branch at initialization time, depending on the truth value of the logical expression *ia R ib*. The branch is taken only if the result is true.

**if...kgoto** -- conditional branch during performance time, depending on the truth value of the logical expression *ka R kb*. The branch is taken only if the result is true.

**if...goto** -- combination of the above. Condition tested on every pass.

**if...then** -- allows the ability to specify conditional *if/else/endif* blocks. All *if...then* blocks must end with an *endif* statement. *elseif* and *else* statements are optional. Any number of *elseif* statements are allowed. Only one *else* statement may occur and it must be the last conditional statement before the *endif* statement. Nested *if...then* blocks are allowed.

### Note

Note that if the condition uses a k-rate variable (for instance, “if *kval > 0*”), the *if...goto* or *if...then* statement will be ignored during the i-time pass. This allows for opcode initialization, even if the k-rate variable has already been assigned an appropriate value by an earlier init statement.

## Syntax

```
if ia R ib igoto label  
  
if ka R kb kgoto label  
  
if xa R xb goto label  
  
if xa R xb then
```

where *label* is in the same instrument block and is not an expression, and where *R* is one of the Relational operators (*<*, *=*, *<=*, *==*, *!=*) (and *=* for convenience, see also under *Conditional Values*).

If *goto* or *then* is used instead of *kgoto* or *igoto*, the behavior is determined by the type being compared. If the comparison used k-type variables, *kgoto* is used and viceversa.

### Note

*If/then/goto* statements cannot do audio-type comparisons. You can't put a-type variables in the comparison expressions for these opcodes. The reason for this is that audio variables are actually vectors, which can't be compared in the same way as scalars. If you need to compare individual audio samples, use *kr = 1* or *Comparators*.

## Examples

Here is an example of the if...igoto combination. It uses the file *igoto.csd* [examples/igoto.csd].

### Example 380. Example of the if...igoto combination.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# fftinv

fftinv — Complex-to-complex Inverse Fast Fourier Transform.

## Description

Applies an Inverse Fast Fourier Transform to a complex-value input 1-dimensional array producing a complex-valued output. The output is another array containing the complex-valued signal, and both arrays are arranged in interleaved real-imaginary format. The output array will have the same size as the input, and the transform size will be equivalent to half of the length of the array. Non-power-of-two transforms are limited to even sizes with not too many factors.

## Syntax

```
kout[] fftinv kin[]
```

## Performance

*kout[]* -- output array containing the complex-valued output. It will be created if it does not exist.

*kin[]* -- input array containing the complex-valued input.

## Examples

Here is an example of the fftinv opcode. It uses the file *ifft.csd* [examples/ifft.csd].

### Example 383. Example of the fftinv opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# ihold

ihold — Creates a held note.

## Description

Causes a finite-duration note to become a “held” note

## Syntax

**ihold**

## Performance

*ihold* -- this i-time statement causes a finite-duration note to become a “held” note. It thus has the same effect as a negative p3 ( see score *i Statement*), except that p3 here remains positive and the instrument reclassifies itself to being held indefinitely. The note can be turned off explicitly with *turnoff*, or its space taken over by another note of the same instrument number (i.e. it is tied into that note). Effective at i-time only; no-op during a *reinit* pass.

## Examples

Here is an example of the ihold opcode. It uses the file *ihold.csd* [examples/ihold.csd].

### Example 385. Example of the ihold opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# imagegetpixel

`imagegetpixel` — Return the RGB pixel values of a previously opened or created image.

## Description

Return the RGB pixel values of a previously opened or created image. An image can be loaded with `imagedload`. An empty image can be created with `imagecreate`.

## Syntax

```
ared, agreeen, ablue imagegetpixel iimagenum, ax, ay
```

```
kred, kgreen, kblue imagegetpixel iimagenum, kx, ky
```

## Initialization

*iimagenum* -- the reference of the image.. It should be a value returned by `imagedload` or `imagecreate`.

## Performance

*ax (kx)* -- horizontal pixel position (must be a float from 0 to 1).

*ay (ky)* -- vertical pixel position (must be a float from 0 to 1).

*ared (kred)* -- red value of the pixel (mapped to a float from 0 to 1).

*agreeen (kgreen)* -- green value of the pixel (mapped to a float from 0 to 1).

*ablue (kblue)* -- blue value of the pixel (mapped to a float from 0 to 1).

## Examples

Here is an example of the `imagegetpixel` opcode. It uses the files `imageopcodesdemo2.csd` [examples/`imageopcodesdemo2.csd`] `test1.png` [examples/test1.png] and `test2.png` [examples/test2.png].

### Example 388. Example of the `imagegetpixel` opcode.

```

# imagedload

imagedload — Load an image.

## Description

Load an image and return a reference to it. Individual pixel values can then be accessed with *imagegetpixel*.

### Note

The image processing opcodes can only load png images

## Syntax

```
iimagenum imagedload filename
```

## Initialization

*iimagenum* -- number assigned to the loaded image.

*filename* -- The filename of the image to load (should be a valid PNG image file).

## Examples

Here is an example of the imagedload opcode. It uses the file *imageopcodes.csd* [examples/imageopcodes.csd].

### Example 389. Example of the imagedload opcode.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-n ;no sound output
</CsOptions>
<CsInstruments>

sr=48000
ksmps=1
nchnls=2

; this test .csd copies image.png into a new file 'imageout.png'

giimage1 imagedload "image.png"
giimagew, giimageh imagesize giimage1
giimage2 imagecreate giimagew,giimageh

# imagesave

imagesave — Save a previously created image.

## Description

Save a previously created image. An empty image can be created with *imagecreate* and its pixel RGB values can be set with *imagesetpixel*. The image will be saved in PNG format.

## Syntax

```
imagesave iimagenum, filename
```

## Initialization

*iimagenum* -- the reference of the image to be save. It should be a value returned by *imagecreate*.

*filename* -- The filename to use to save the image.

## Examples

Here is an example of the imagesave opcode. It uses the file *imageopcodes.cs* [examples/imageopcodes.cs].

### Example 390. Example of the imagesave opcode.

```
<CsoundSynthesizer>

# imagesetpixel

`imagesetpixel` — Set the RGB value of a pixel inside a previously opened or created image.

## Description

Set the RGB value of a pixel inside a previously opened or created image. An image can be loaded with `imagedload`. An empty image can be created with `imagecreate` and saved with `imagesave`.

## Syntax

```
imagesetpixel iimagenum, ax, ay, ared, agreen, ablue
```

```
imagesetpixel iimagenum, kx, ky, kred, kgreen, kblue
```

## Initialization

*iimagenum* -- the reference of the image.. It should be a value returned by `imagedload` or `imagecreate`.

## Performance

*ax (kx)* -- horizontal pixel position (must be a float from 0 to 1).

*ay (ky)* -- vertical pixel position (must be a float from 0 to 1).

*ared (kred)* -- red value of the pixel (mapped to a float from 0 to 1).

*agreen (kgreen)* -- green value of the pixel (mapped to a float from 0 to 1).

*ablue (kblue)* -- blue value of the pixel (mapped to a float from 0 to 1).

## Examples

Here is an example of the `imagesetpixel` opcode. It uses the file `imageopcodes.cs` [examples/imageopcodes.cs].

### Example 391. Example of the `imagesetpixel` opcode.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-n ;no sound output
</CsOptions>
<CsInstruments>

# imagesize

`imagesize` — Return the width and height of a previously opened or created image.

## Description

Return the width and height of a previously opened or created image. An image can be loaded with `imagedload`. An empty image can be created with `imagecreate`.

## Syntax

```
iwidth, iheight imagesize iimagenum
```

## Initialization

*iimagenum* -- the reference of the image.. It should be a value returned by `imagedload` or `imagecreate`.

*iwidth* -- image width.

*iheight* -- image height.

## Examples

Here is an example of the `imagesize` opcode. It uses the file `imageopcodes.cs` [examples/imageopcodes.cs].

### Example 392. Example of the `imagesize` opcode.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-n ;no sound output
</CsOptions>
<CsInstruments>

sr=48000
ksmps=1
nchnls=2

; this test .csd copies image.png into a new file 'imageout.png'

giimage1 imagedload "image.png"
giimage2, giimageh imagesize giimage1
giimage2 imagecreate giimagew,giimageh

# in

in — Reads mono audio data from an external device or stream.

## Description

Reads audio data from an external device or stream.

### Warning

There are two versions of this opcode. The first is designed to be used only with orchestras that have ichnls=1. Doing so with orchestras with ichnls > 1 will cause incorrect audio input.

The second form will read multiple channels into an array.

## Syntax

```
arl in
```

```
aarray in
```

## Performance

Form 1 reads mono audio data from an external device or stream. If the command-line *-i* flag is set, sound is read continuously from the audio input stream (e.g. *stdin* or a soundfile) into an internal buffer. Any number of these opcodes can read freely from this buffer.

The second format will read upto ichnls of audio into an audio array, which must be initialised.

## Examples

Here is an example of the in opcode. It uses the file *in.csd* [examples/in.csd].

### Example 393. Example of the in opcode.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac -idac ;;;realtime audio I/O
; For Non-realtime ouput leave only the line below:
; in.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1 ;1 channel in, two channels out
ain1 in ;grab your mic and sing
adel linseg 0, p3*.5, 0.02, p3*.5, 0 ;max delay time = 20ms
```

```
aout flanger ainl, adel, .7
      fout "in_1.wav", 14, aout, aout ;write to stereo file,
      outs aout, aout           ;16 bits with header

endin
</CsInstruments>

# in32

in32 — Reads a 32-channel audio signal from an external device or stream.

## Description

Reads a 32-channel audio signal from an external device or stream.

### Warning

This opcode is designed to be used only with orchestras that have *nchnls\_i*=32. Doing so with orchestras with *nchnls\_i* > 32 will cause incorrect audio input.

## Syntax

```
ar1, ar2, ar3, ar4, ar5, ar6, ar7, ar8, ar9, ar10, ar11, ar12, ar13, ar14, \
ar15, ar16, ar17, ar18, ar19, ar20, ar21, ar22, ar23, ar24, ar25, ar26, \
ar27, ar28, ar29, ar30, ar31, ar32 in32
```

## Performance

*in32* reads a 32-channel audio signal from an external device or stream. If the command-line *-i* flag is set, sound is read continuously from the audio input stream (e.g. *stdin* or a soundfile) into an internal buffer.

# inch

inch — Reads from numbered channels in an external audio signal or stream.

## Description

Reads from numbered channels in an external audio signal or stream.

## Syntax

```
ain1[, ...] inch kchan1[,...]
```

## Performance

*ain1, ...* - input audio signals

*kchan1,...* - channel numbers

*inch* reads from numbered channels determined by the corresponding *kchan* into the associated *ain*. If the command-line *-i* flag is set, sound is read continuously from the audio input stream (e.g. *stdin* or a soundfile). *inch* can also be used to receive audio in realtime from the audio interface using *-iadc*.

### Note

The highest number for *kchan* available for use with *inch* depends on *nchnls\_i*. If *kchan* is greater than *nchnls\_i*, *ain* will be silent. Note that *inch* will give a warning but not an error in this case.

## Examples

Here is an example of the inch opcode. It uses the file *inch.csd* [examples/inch.csd].

### Example 394. Example of the inch opcode.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac -idac ;;;realtime audio I/O
; For Non-realtime output leave only the line below:

# inh

inh — Reads six-channel audio data from an external device or stream.

## Description

Reads six-channel audio data from an external device or stream.

### Warning

This opcode is designed to be used only with orchestras that have `nchnls_i=6`. Doing so with orchestras with `nchnls_i > 6` will cause incorrect audio input.

## Syntax

```
ar1, ar2, ar3, ar4, ar5, ar6 inh
```

## Performance

Reads six-channel audio data from an external device or stream. If the command-line `-i` flag is set, sound is read continuously from the audio input stream (e.g. `stdin` or a soundfile) into an internal buffer. Any number of these opcodes can read freely from this buffer.

# init

init — Puts the value of the i-time expression into a k-, a-rate or t- variable.

## Syntax

```
ares init iarg  
  
ires init iarg  
  
kres init iarg  
  
ares, ... init iarg, ...  
  
ires, ... init iarg, ...  
  
kres, ... init iarg, ...  
  
tab init isize[, ival]
```

## Description

Put the value of the i-time expression into a k- or a-rate variable.

## Initialization

Puts the value of the i-time expression *iarg* into a k-, a-rate or t- variable, i.e., initialize the result. Note that **init** provides the only case of an init-time statement being permitted to write into a perf-time (k- or a-rate) result cell; the statement has no effect at perf-time.

Since version 5.13 it is possible to initialise upto 24 variables of the same class in one statement. If there are more output variables than input expressions then the last one is repeated. It is an error to have more inputs than outputs.

The t-variable form was introduced in 5.14 and allocated space for a vector or the given size, initialised to the given value (default value is zero).

## Examples

Here is an example of the init opcode. It uses the file *init.csd* [examples/init.csd].

### Example 395. Example of the init opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>

# initc14

`initc14` — Initializes the controllers used to create a 14-bit MIDI value.

## Description

Initializes the controllers used to create a 14-bit MIDI value.

## Syntax

```
initc14 ichan, ictlno1, ictlno2, ivalue
```

## Initialization

*ichan* -- MIDI channel (1-16)

*ictlno1* -- most significant byte controller number (0-127)

*ictlno2* -- least significant byte controller number (0-127)

*ivalue* -- floating point value (must be within 0 to 1)

## Performance

`initc14` can be used together with both `midic14` and `ctrl14` opcodes for initializing the first controller's value. *ivalue* argument must be set with a number within 0 to 1. An error occurs if it is not. Use the following formula to set *ivalue* according with `midic14` and `ctrl14` min and max range:

$$\text{ivalue} = (\text{initial\_value} - \text{min}) / (\text{max} - \text{min})$$

## See Also

Thanks goes to Rasmus Ekman for pointing out the correct MIDI channel and controller number ranges.

# initc21

`initc21` — Initializes the controllers used to create a 21-bit MIDI value.

## Description

Initializes the controllers used to create a 21-bit MIDI value.

## Syntax

```
initc21 ichan, ictlno1, ictlno2, ictlno3, ivalue
```

## Initialization

*ichan* -- MIDI channel (1-16)

*ictlno1* -- most significant byte controller number (0-127)

*ictlno2* -- medium significant byte controller number (0-127)

*ictlno3* -- least significant byte controller number (0-127)

*ivalue* -- floating point value (must be within 0 to 1)

## Performance

`initc21` can be used together with both `midic21` and `ctrl21` opcodes for initializing the first controller's value. *ivalue* argument must be set with a number within 0 to 1. An error occurs if it is not. Use the following formula to set *ivalue* according with `midic21` and `ctrl21` min and max range:

$$\text{ivalue} = (\text{initial\_value} - \text{min}) / (\text{max} - \text{min})$$

## See Also

New in Csound version 3.47

Thanks goes to Rasmus Ekman for pointing out the correct MIDI channel and controller number ranges.

# initc7

initc7 — Initializes the controller used to create a 7-bit MIDI value.

## Description

Initializes MIDI controller *ictlno* with *ivalue*

## Syntax

```
initc7 ichan, ictlno, ivalue
```

## Initialization

*ichan* -- MIDI channel (1-16)

*ictlno* -- controller number (0-127)

*ivalue* -- floating point value (must be within 0 to 1)

## Performance

*initc7* can be used together with both *midic7* and *ctrl7* opcodes for initializing the first controller's value. *ivalue* argument must be set with a number within 0 to 1. An error occurs if it is not. Use the following formula to set *ivalue* according with *midic7* and *ctrl7* min and max range:

$$\text{ivalue} = (\text{initial\_value} - \text{min}) / (\text{max} - \text{min})$$

## Examples

Here is an example of the *initc7* opcode. It uses the file *initc7.csd* [examples/initc7.csd].

### Example 396. Example of the initc7 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# inleta

inleta — Receives an arate signal into an instrument through a named port.

## Description

Receives an arate signal into an instrument through a named port.

## Syntax

```
asignal inleta Sname
```

## Initialization

*Sname* -- String name of the inlet port. The name of the inlet is implicitly qualified by the instrument name or number, so it is valid to use the same inlet name in more than one instrument (but not to use the same inlet name twice in one instrument).

## Performance

*asignal* -- audio input signal

During performance, the arate inlet signal is received from each instance of an instrument containing an outlet port to which this inlet has been connected using the connect opcode. The signals of all the outlets connected to an inlet are summed in the inlet.

## Examples

Here is an example of the inleta opcode. It uses the file *inleta.csd* [examples/inleta.csd].

### Example 397. Example of the inleta opcode.

```
<CsoundSynthesizer>

# inletkid

inletkid — Receives a krate signal into an instrument from a named port.

## Description

Receives a krate signal into an instrument from a named port.

## Syntax

```
ksignal inletkid Sname, SinstanceID
```

## Initialization

*Sname* -- String name of the inlet port. The name of the inlet is implicitly qualified by the instrument name or number, so it is valid to use the same inlet name in more than one instrument (but not to use the same inlet name twice in one instrument).

*SinstanceID* -- String name of the outlet port's instance ID. This enables the inlet to discriminate between different instances of the outlet, e.g. one instance of the outlet might be created by a note specifying one instance ID, and another instance might be created by a note specifying another ID. This might be used, e.g., to situate difference instances of an instrument at different points in an Ambisonic space in a spatializing effects processor.

## Performance

*ksignal* -- krate input signal

During performance, the krate inlet signal is received from each instance of an instrument containing an outlet port to which this inlet has been connected using the connect opcode. The signals of all the outlets that are connected to an inlet, but only those share the specified instance ID, are summed in the inlet.

# inletf

inletf — Receives an frate signal (fsig) into an instrument from a named port.

## Description

Receives an frate signal (fsig) into an instrument from a named port.

## Syntax

```
fsignal inletf Sname
```

## Initialization

*Sname* -- String name of the inlet port. The name of the inlet is implicitly qualified by the instrument name or number, so it is valid to use the same inlet name in more than one instrument (but not to use the same inlet name twice in one instrument).

## Performance

*ksignal* -- frate input signal

During performance, the frate inlet signal is received from each instance of an instrument containing an outlet port to which this inlet has been connected using the connect opcode. The signals of all the outlets connected to an inlet are combined in the inlet.

# ino

ino — Reads eight-channel audio data from an external device or stream.

## Description

Reads eight-channel audio data from an external device or stream.

### Warning

This opcode is designed to be used only with orchestras that have `nchnls_i=8`. Doing so with orchestras with `nchnls_i > 8` will cause incorrect audio input.

## Syntax

```
ar1, ar2, ar3, ar4, ar5, ar6, ar7, ar8 ino
```

## Performance

Reads eight-channel audio data from an external device or stream. If the command-line `-i` flag is set, sound is read continuously from the audio input stream (e.g. `stdin` or a soundfile) into an internal buffer. Any number of these opcodes can read freely from this buffer.

## See Also

# inq

inq — Reads quad audio data from an external device or stream.

## Description

Reads quad audio data from an external device or stream.

### Warning

This opcode is designed to be used only with orchestras that have nchnls\_i=4. Doing so with orchestras with nchnls\_i > 4 will cause incorrect audio input.

## Syntax

```
ar1, ar2, ar3, a4 inq
```

## Performance

Reads quad audio data from an external device or stream. If the command-line *-i* flag is set, sound is read continuously from the audio input stream (e.g. *stdin* or a soundfile) into an internal buffer. Any number of these opcodes can read freely from this buffer.

## Examples

Here is an example of the inq opcode. It uses the file *inq.csd* [examples/inq.csd].

### Example 399. Example of the inq opcode.

# inrg

inrg — Allow input from a range of adjacent audio channels from the audio input device

## Description

*inrg* reads audio from a range of adjacent audio channels from the audio input device.

## Syntax

```
inrg kstart, ain1 [,ain2, ain3, ..., ainN]
```

## Performance

*kstart* - the number of the first channel of the input device to be accessed (channel numbers starts with 1, which is the first channel)

*ain1, ain2, ... ainN* - the output arguments filled with the incoming audio coming from corresponding channels.

*inrg* allows input from a range of adjacent channels from the input device. *kstart* indicates the first channel to be accessed (channel 1 is the first channel). The user must be sure that the number obtained by summing *kstart* plus the number of accessed channels -1 is  $\leq nchnls\_i$ .

### Note

Note that this opcode is exceptional in that it produces its “output” on the parameters to the right.

# insremot

*insremot* — An opcode which can be used to implement a remote orchestra. This opcode will send note events from a source machine to one destination.

## Description

With the *insremot* and *insglobal* opcodes you are able to perform instruments on remote machines and control them from a master machine. The remote opcodes are implemented using the master/client model. All the machines involved contain the same orchestra but only the master machine contains the information of the score. During the performance the master machine sends the note events to the clients. The *insremot* opcode will send events from a source machine to one destination if you want to send events to many destinations (broadcast) use the *insglobal* opcode instead. These two opcodes can be used in combination.

## Syntax

```
insremot idestination, isource, instrnum [,instrnum...]
```

## Initialization

*idestination* -- a string that is the intended client computer (e.g. 192.168.0.100). This is the destination host which receives the events from the given instrument.

*isource* -- a string that is the intended server computer (e.g. 192.168.0.100). This is the source host which generates the events of the given instrument and sends it to the address given by *idestination*.

*instrnum* -- a list of instrument numbers which will be played on the destination machine

## Performance

### Note

If is essential the computers using this opcode have the same byte-order, data size (double or float) and pointer size. One cannot use it with mixed 32 and 64 computers for instance.

### Note

Internally this opcode may make use of the `gethostname` and `gethostbyname` functions to determine the client's and server's IP address for checking which messages are for which machine, or on non-windows system other techniques. If a computer has more than one IP address there is no way to control which IP address is found (but see below). On non-windows systems the default network is `eth0` or `en0`, and if that fails `wlan0`. (Since version 6.05) the network to be used can be set with an environment variable `CS_ETHER`.

### Note

The remote operation does not allow the sending of strings at all.

## Examples

Here is an example of the insremot opcode. It uses the files *insremot.csd* [examples/insremot.csd] and *insremotM.csd* [examples/insremotM.csd].

### Example 401. Example of the insremot opcode.

The simple example below shows the bilbar example played on a remote machine. The master machine is named "192.168.1.100" and the client "192.168.1.101". Start the client on the machine (it will wait to receive the events from the master machine) and then start the master. Here is the command on linux to start a client (csound -+rtaudio=alsa -odac -dm0 insremot.csd), and the command on the master machine will look like this (csound -+rtaudio=alsa -odac -dm0 insremotM.csd).

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# insglobal

`insglobal` — An opcode which can be used to implement a remote orchestra. This opcode will send note events from a source machine to many destinations.

## Description

With the `insremot` and `insglobal` opcodes you are able to perform instruments on remote machines and control them from a master machine. The remote opcodes are implemented using the master/client model. All the machines involved contain the same orchestra but only the master machine contains the information of the score. During the performance the master machine sends the note events to the clients. The `insglobal` opcode sends the events to all the machines involved in the remote concert. These machines are determined by the `insremot` definitions made above the `insglobal` command. To send events to only one machine use `insremot`.

## Syntax

```
insglobal isource, instrnum [,instrnum...]
```

## Initialization

`isource` -- a string that is the intended server computer (e.g. 192.168.0.100). This is the source host which generates the events of the given instrument(s) and sends it to all the machines involved in the remote concert.

`instrnum` -- a list of instrument numbers which will be played on the destination machines

## Performance

### Note

If is essential the computers using this opcode have the same byte-order, data size (double or float) and pointer size. One cannot use it with mixed 32 and 64 computers for instance.

### Note

Internally this opcode makes use of the `gethostname` and `gethostbyname` functions to determine the client's and server's IP address for checking which messages are for which machine. If a computer has more than one IP address there is no way to control which IP address is found.

### Note

The remote operation does not allow the sending of strings at all.

## Examples

See the entry for `insremot` for an example of usage.

# instr

instr — Starts an instrument block.

## Description

Starts an instrument block.

## Syntax

```
instr i, j, ...
```

## Initialization

Starts an instrument block defining instruments  $i, j, \dots$

$i, j, \dots$  must be numbers, not expressions. Any positive integer is legal, and in any order, but excessively high numbers are best avoided.

### Note

There may be any number of instrument blocks in an orchestra.

Instruments can be defined in any order (but they will always be both initialized and performed in ascending instrument number order, with the exception of notes triggered by real time events that are initialized in the order of being received but still performed in ascending instrument number order). Instrument blocks cannot be nested (i.e. one block cannot contain another).

## Examples

Here is an example of the instr opcode. It uses the file *instr.csd* [examples/instr.csd].

### Example 402. Example of the instr opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# int

int — Extracts an integer from a decimal number.

## Description

Returns the integer part of  $x$ .

## Syntax

```
int(x)  (init-rate or control-rate; also works at audio rate in Csound5)
```

where the argument within the parentheses may be an expression. Value converters perform arithmetic translation from units of one kind to units of another. The result can then be a term in a further expression.

## Examples

Here is an example of the int opcode. It uses the file *int.csd* [examples/int.csd].

### Example 403. Example of the int opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac    ;;;realtime audio out
;-iadc   ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime output leave only the line below:
;-o int.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1
icount init 0
loop:
    inum = icount / 3
    inm = int(inum)
    prints "integer (%f/3) = %f\n", icount, inm
loop_lt icount, 1, 10, loop
endin
</CsInstruments>
<CsScore>

i 1 0 0
e
</CsScore>
</CsoundSynthesizer>
```

Its output should include lines like these:

```
integer (0.000000/3) = 0.000000
integer (1.000000/3) = 0.000000
integer (2.000000/3) = 0.000000
integer (3.000000/3) = 1.000000
integer (4.000000/3) = 1.000000
integer (5.000000/3) = 1.000000
integer (6.000000/3) = 2.000000
integer (7.000000/3) = 2.000000
integer (8.000000/3) = 2.000000
integer (9.000000/3) = 3.000000
```

# integ

integ — Modify a signal by integration.

## Description

Modify a signal by integration.

## Syntax

```
ares integ asig [, iskip]  
  
kres integ ksig [, iskip]
```

## Initialization

*iskip* (optional) -- initial disposition of internal save space (see *reson*). The default value is 0.

## Performance

*integ* and *diff* perform integration and differentiation on an input control signal or audio signal. Each is the converse of the other, and applying both will reconstruct the original signal. Since these units are special cases of low-pass and high-pass filters, they produce a scaled (and phase shifted) output that is frequency-dependent. Thus *diff* of a sine produces a cosine, with amplitude  $2 * \pi * \text{Hz} / \text{sr}$  that of the original (for each component partial); *integ* will inversely affect the magnitudes of its component inputs. With this understanding, these units can provide useful signal modification.

## Examples

Here is an example of the *integ* opcode. It uses the file *integ.csd* [examples/integ.csd].

### Example 404. Example of the integ opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# interp

interp — Converts a control signal to an audio signal using linear interpolation.

## Description

Converts a control signal to an audio signal using linear interpolation.

## Syntax

```
ares interp ksig [, iskip] [, imode]
```

## Initialization

*iskip* (optional, default=0) -- initial disposition of internal save space (see *reson*). The default value is 0.

*imode* (optional, default=0) -- sets the initial output value to the first k-rate input instead of zero. The following graphs show the output of interp with a constant input value, in the original, when skipping init, and in the new mode:

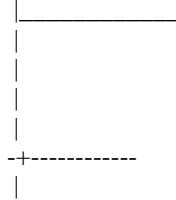

### Example 405. iskip=0, imode=0

```
| _____  
| /  
| /  
| /  
|/  
+-----  
|
```

### Example 406. iskip=1, imode=0

| _____  
| /  
|/  
|  
|  
+-----  
|
```

### Example 407. iskip=0, imode=1

## Performance

*ksig* -- input k-rate signal.

*interp* converts a control signal to an audio signal. It uses linear interpolation between successive kvals.

## Examples

Here is an example of the *interp* opcode. It uses the file *interp.csd* [examples/interp.csd].

### Example 408. Example of the interp opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# invalue

`invalue` — Reads a k-rate signal from a user-defined channel.

## Description

Reads a k-rate or i-rate signal or string from a user-defined channel.

## Syntax

```
ivalue invalue "channel name"  
  
kvalue invalue "channel name"  
  
Sname invalue "channel name"
```

## Performance

*ivalue, kvalue* -- The value that is read from the channel.

*Sname* -- The string variable that is read from the channel.

*"channel name"* -- An integer, string (in double-quotes), or string variable identifying the channel.

## Examples

Here is an example of the `invalue` opcode. It uses the file *invalue.csd* [examples/invalue.csd].

### Example 409. Example of the `invalue` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# inx

inx — Reads a 16-channel audio signal from an external device or stream.

## Description

Reads a 16-channel audio signal from an external device or stream.

### Warning

This opcode is designed to be used only with orchestras that have nchnls=16. Doing so with orchestras with nchnls > 16 will cause incorrect audio input.

## Syntax

```
ar1, ar2, ar3, ar4, ar5, ar6, ar7, ar8, ar9, ar10, ar11, ar12, \
ar13, ar14, ar15, ar16 inx
```

## Performance

*inx* reads a 16-channel audio signal from an external device or stream. If the command-line *-i* flag is set, sound is read continuously from the audio input stream (e.g. *stdin* or a soundfile) into an internal buffer.

## inz

inz — Reads multi-channel audio samples into a ZAK array from an external device or stream.

## Description

Reads multi-channel audio samples into a ZAK array from an external device or stream.

## Syntax

```
inz ksig1
```

## Performance

*inz* reads audio samples in *nchnls* into a ZAK array starting at *ksig1*. If the command-line *-i* flag is set, sound is read continuously from the audio input stream (e.g. *stdin* or a soundfile) into an internal buffer.

# JackoAudioIn

JackoAudioIn — Receives an audio signal from a Jack port.

## Note

plugin: Requires jacko plugin

## Description

Receives an audio signal from a Jack audio input port inside this instance of Csound, which in turn has received the signal from its connected external Jack audio output port.

## Syntax

```
asignal JackoAudioIn ScsoundPortName
```

## Initialization

*ScsoundPortName* -- The short name ("portname") of the internal Jack audio input port.

## Performance

*asignal* -- Audio received from the external Jack output port to which ScsoundPortName is connected.

## See Also

*JackoInfo, JackoInfo, JackoFreewheel, JackoAudioOutConnect, JackoAudioOutConnect, JackoMidiIn-Connect, JackoMidiOutConnect, JackoOn, JackoAudioOut, JackoMidiOut, JackoNoteOut, JackoTrans-port.*

## Credits

By: Michael Gogins 2010

# JackoAudioInConnect

JackoAudioInConnect — Creates an audio connection from a Jack port to Csound.

## Note

plugin: Requires jacko plugin

## Description

In the orchestra header, creates an audio connection from an external Jack audio output port to a Jack audio input port inside this instance of Csound.

## Syntax

```
JackoAudioInConnect SexternalPortName, ScsoundPortName
```

## Initialization

*SexternalPortName* -- The full name ("clientname:portname") of an external Jack audio output port.

*ScsoundPortName* -- The short name ("portname") of the internal Jack audio input port.

## Performance

The actual audio must be read with the JackoAudioIn opcode.

## See Also

*JackoInfo, JackoInfo, JackoFreewheel, JackoAudioOutConnect, JackoMidiInConnect, JackoMidiOut-Connect, JackoOn, JackoAudioIn, JackoAudioOut, JackoMidiOut, JackoNoteOut, JackoTransport.*

## Credits

By: Michael Gogins 2010

# JackoAudioOut

JackoAudioOut — Sends an audio signal to a Jack port.

## Note

plugin: Requires jacko plugin

## Description

Sends an audio signal to an internal Jack audio output port, and in turn to its connected external Jack audio input port.

Note that it is possible to send audio out via Jack to the system audio interface, while at the same time rendering to a regular Csound output soundfile.

## Syntax

```
JackoAudioOut  ScsoundPortName, asignal
```

## Initialization

*ScsoundPortName* -- The short name ("portname") of the internal Jack audio output port.

## Performance

*asignal* -- Audio to be sent to the external Jack audio input port to which CsoundPortName is connected.

Audio from multiple instances of the opcode sending to the same Jack port is summed before sending.

## See Also

*JackoInfo, JackoInfo, JackoFreewheel, JackoAudioOutConnect, JackoMidiInConnect, JackoMidiOut-Connect, JackoOn, JackoAudioIn, JackoMidiOut, JackoMidiOut, JackoTransport.*

# JackoAudioOutConnect

JackoAudioOutConnect — Creates an audio connection from Csound to a Jack port.

## Note

plugin: Requires jacko plugin

## Description

In the orchestra header, creates an audio connection from a Jack audio output port inside this instance of Csound to an external Jack audio input port.

## Syntax

```
JackoAudioOutConnect  ScsoundPortName,  SexternalPortName
```

## Initialization

*ScsoundPortName* -- The short name ("portname") of the internal Jack audio output port.

*SexternalPortName* -- The full name ("clientname:portname") of an external Jack audio input port.

## Performance

The actual audio must be written with the JackoAudioOut opcode.

## See Also

*The Jacko Opcodes, JackoInfo, JackoInfo, JackoFreewheel, JackoAudioOutConnect, JackoMidiInConnect, JackoMidiOutConnect, JackoOn, JackoAudioIn, JackoAudioOut, JackoMidiOut, JackoNoteOut, JackoTransport.*

## Credits

By: Michael Gogins 2010

# JackoFreewheel

JackoFreewheel — Turns Jack's freewheeling mode on or off.

## Note

plugin: Requires jacko plugin

## Description

Turns Jack's freewheeling mode on or off.

When freewheeling is on, if supported by the rest of the Jack system, Csound will run as fast as possible, which may be either faster or slower than real time.

This is essential for rendering scores that are too dense for real-time performance to a soundfile, without xruns or dropouts.

## Syntax

```
JackoFreewheel [ienabled]
```

## Initialization

*ienabled* -- Turns freewheeling on (the default) or off.

## See Also

# JackoInfo

JackoInfo — Prints information about the Jack system.

## Note

plugin: Requires jacko plugin

## Description

Prints the Jack daemon and client names, the sampling rate and frames per period, and all active Jack port names, types, states, and connections.

## Syntax

`JackoInfo`

## Initialization

May be called any number of times in the orchestra header, for example both before and after creating Jack ports in the Csound orchestra header.

## Examples

Here is an example of the JackoInfo opcode. It uses the file *JackInfo.csd* [examples/JackoInfo.csd].

### Example 410. Example of the JackoInfo opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>

# JackoInit

JackoInit — Initializes Csound as a Jack client.

## Note

plugin: Requires jacko plugin

## Description

Initializes this instance of Csound as a Jack client.

Csound's sr must be equal to the Jack daemon's frames per second.

Csound's ksmmps must be equal to the Jack daemon's frames per period.

Frames per period must not only (a) be a power of 2, but also (b) go evenly into the frames per second, e.g. 128 frames per period goes into 48000 frames per second 375 times, for a latency or MIDI time granularity of about 2.7 milliseconds (as good as or better than the absolute best human performers).

The order of processing of all signals that pass from Jack input ports, through Csound processing, and to Jack output ports, must be properly determined by sequence of instrument and opcode definition within Csound.

## Syntax

```
JackoInit SclientName, ServerName
```

## Initialization

*Sname* -- String name of the inlet port. The name of the inlet is implicitly qualified by the instrument name or number, so it is valid to use the same inlet name in more than one instrument (but not to use the same inlet name twice in one instrument).

*SclientName* -- The name of the Jack client; normally, should be "csound".

*ServerName* -- The name of the Jack daemon; normally, will be "default".

This opcode must be called once and only once in the orchestra header, and before any other Jack opcodes. If more than one instance of Csound is using the Jack opcodes at the same time, then each instance of Csound must use a different client name.

## Examples

Here is an example of the JackoInit opcode. It uses the file *JackoInit.csd* [examples/JackoInit.csd].

### Example 411. Example of the JackoInit opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# JackoMidiInConnect

JackoMidiInConnect — Creates a MIDI connection from a Jack port to Csound.

## Note

plugin: Requires jacko plugin

## Description

In the orchestra header, creates a MIDI connection from an external Jack MIDI output port to this instance of Csound.

## Syntax

```
JackoMidiInConnect SexternalPortName, ScsoundPortName
```

## Initialization

*SexternalPortName* -- The full name ("clientname:portname") of an external Jack MIDI output port.

*ScsoundPortName* -- The short name ("portname") of the internal Jack MIDI input port.

Must be used in conjunction with the -M0 -+rtmidi=null Csound command-line options. Can be used in with the MIDI inter-operability command-line options and/or opcodes to enable the use of ordinary Csound instrument definitions to render external scores or MIDI sequences.

Note that Csound can connect to ALSA ports through Jack, but in that case you will have to identify the port by its alias in the JackInfo printout.

## Performance

The actual MIDI events will be received in the regular Csound way, i.e. through a MIDI driver and the sensevents mechanism, rather than through a Jack input port opcode.

The granularity of timing is Csound's kperiod.

## See Also

*JackoInfo, JackoInfo, JackoFreewheel, JackoAudioOutConnect, JackoAudioOutConnect, JackoMidiOutConnect, JackoOn, JackoAudioIn, JackoAudioOut, JackoMidiOut, JackoNoteOut, JackoTransport.*

# JackoMidiOutConnect

JackoMidiOutConnect — Creates a MIDI connection from Csound to a Jack port.

## Note

plugin: Requires jacko plugin

## Description

In the orchestra header, creates a connection from a Jack MIDI output port inside this instance of Csound to an external Jack MIDI input port.

## Syntax

```
JackoMidiOutConnect ScsoundPortName, SexternalPortName
```

## Initialization

*ScsoundPortName* -- The short name ("portname") of the internal Jack MIDI output port.

*SexternalPortName* -- The full name ("clientname:portname") of an external Jack MIDI input port.

## Performance

The actual MIDI data must be written with the JackoMidiOut or JackoNoteOut opcodes.

## See Also

# JackoMidiOut

JackoMidiOut — Sends a MIDI channel message to a Jack port.

## Note

plugin: Requires jacko plugin

## Description

Sends a MIDI channel message to a Jack MIDI output port inside this instance of Csound, and in turn to its connected external Jack MIDI input port.

## Syntax

```
JackoMidiOut  ScsoundPortName, kstatus, kchannel, kdata1[, kdata2]
```

## Initialization

*ScsoundPortName* -- The short name ("portname") of the internal Jack MIDI output port.

## Performance

*kstatus* -- MIDI status byte; must indicate a MIDI channel message.

*kchannel* -- MIDI channel (from 0 through 15).

*kdata1* -- First data byte of a MIDI channel message.

*kdata2* -- Optional second data byte of a MIDI channel message.

This opcode can be called any number of times in the same kperiod. Messages from multiple instances of the opcode sending to the same port are collected before sending.

Running status, system exclusive messages, and real-time messages are not supported.

The granularity of timing is Csound's kperiod.

## See Also

# JackoNoteOut

JackoNoteOut — Sends a MIDI channel message to a Jack port.

## Note

plugin: Requires jacko plugin

## Description

Sends a MIDI channel message to a Jack MIDI output port inside this instance of Csound, and in turn to its connected external Jack MIDI input port.

## Syntax

```
JackoNoteOut  ScsoundPortName, kstatus, kchannel, kdata1[, kdata2]
```

## Initialization

*ScsoundPortName* -- The short name ("portname") of the internal Jack MIDI output port.

## Performance

*kstatus* -- MIDI status byte; must indicate a MIDI channel message.

*kchannel* -- MIDI channel (from 0 through 15).

*kdata1* -- First data byte of a MIDI channel message.

*kdata2* -- Optional second data byte of a MIDI channel message.

This opcode can be called any number of times in the same kperiod. Messages from multiple instances of the opcode sending to the same port are collected before sending.

Running status, system exclusive messages, and real-time messages are not supported.

The granularity of timing is Csound's kperiod.

# JackoOn

JackoOn — Enables or disables all Jack ports.

## Note

plugin: Requires jacko plugin

## Description

In the orchestra header, after all Jack connections have been created, enables or disables all Jack input and output opcodes inside this instance of Csound to read or write data.

## Syntax

```
JackoOn [iactive]
```

## Initialization

*iactive* -- A flag that turns the ports on (the default) or off.

## See Also

*JackoInit, JackoFreewheel, JackoAudioInConnect, JackoAudioOutConnect, JackoMidiInConnect, JackoMidiOutConnect, JackoAudioIn, JackoAudioOut, JackoMidiOut, JackoNoteOut, JackoTransport.*

# JackoTransport

JackoTransport — Control the Jack transport.

## Note

plugin: Requires jacko plugin

## Description

Starts, stops, or repositions the Jack transport. This is useful, e.g., for starting an external sequencer playing to send MIDI messages to Csound.

## Syntax

```
JackoTransport  kcommand, [kposition]
```

## Performance

*kcommand* -- 0 means "no action", 1 starts the transport, 2 stops the transport, and 3 positions the transport to *kposition* seconds from the beginning of performance (i.e. time 0 in the score).

*kposition* -- Time to position to the transport, in seconds from the beginning of performance (i.e. time 0 in the score).

This opcode can be used at init time or during performance.

The granularity of timing is Csound's *kperiod*.

## See Also

*JackoInfo*, *JackoInfo*, *JackoFreewheel*, *JackoAudioOutConnect*, *JackoMidiInConnect*, *JackoMidiOut-Connect*, *JackoOn*, *JackoAudioIn*, *JackoMidiOut*, *JackoNoteOut*.

# jacktransport

jacktransport — Start/stop jack\_transport and can optionally relocate the playback head.

## Note

plugin: Requires jackTransport plugin

## Description

Start/stop jack\_transport and can optionally relocate the playback head.

## Syntax

```
jacktransport icommand [, ilocation]
```

## Initialization

*icommand* -- 1 to start playing, 0 to stop.

*ilocation* -- optional location in seconds to specify where the playback head should be moved. If omitted, the transport is started from current location.

## Note

Since *jacktransport* depends on jack audio connection kit, it will work only on Linux or Mac OS X systems which have the jack server running.

## Examples

Here is a simple example of the jacktransport opcode. It uses the file *jacktransport.csd* [examples/jacktransport.csd].

### Example 412. Simple example of the jacktransport opcode.

```
<CsoundSynthesizer>
<CsOptions>
--+rtaudio=JACK -b 64 --sched -o dac:system:playback_
</CsOptions>
<CsInstruments>

sr      =          44100
ksmps   =          16
nchnls = 2

instr 1
jacktransport p4, p5
    endin

# jitter

*jitter* — Generates a segmented line whose segments are randomly generated.

## Description

Generates a segmented line whose segments are randomly generated.

## Syntax

```
kout jitter kamp, kcpsMin, kcpsMax
```

## Performance

*kamp* -- Amplitude of jitter deviation

*kcpsMin* -- Minimum speed of random frequency variations (expressed in cps)

*kcpsMax* -- Maximum speed of random frequency variations (expressed in cps)

*jitter* generates a segmented line whose segments are randomly generated inside the +*kamp* and -*kamp* interval. Duration of each segment is a random value generated according to *kcpsmin* and *kcpsmax* values.

*jitter* can be used to make more natural and “analog-sounding” some static, dull sound. For best results, it is suggested to keep its amplitude moderate.

## Examples

Here is an example of the jitter opcode. It uses the file *jitter.csd* [examples/jitter.csd].

### Example 413. Example of the jitter opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# jitter2

jitter2 — Generates a segmented line with user-controllable random segments.

## Description

Generates a segmented line with user-controllable random segments.

## Syntax

```
kout jitter2 ktotamp, kamp1, kcps1, kamp2, kcps2, kamp3, kcps3
```

## Performance

*ktotamp* -- Resulting amplitude of jitter2

*kamp1* -- Amplitude of the first jitter component

*kcps1* -- Speed of random variation of the first jitter component (expressed in cps)

*kamp2* -- Amplitude of the second jitter component

*kcps2* -- Speed of random variation of the second jitter component (expressed in cps)

*kamp3* -- Amplitude of the third jitter component

*kcps3* -- Speed of random variation of the third jitter component (expressed in cps)

*jitter2* also generates a segmented line such as *jitter*, but in this case the result is similar to the sum of three *randi* opcodes, each one with a different amplitude and frequency value (see *randi* for more details), that can be varied at k-rate. Different effects can be obtained by varying the input arguments.

*jitter2* can be used to make more natural and “analog-sounding” some static, dull sound. For best results, it is suggested to keep its amplitude moderate.

## Examples

Here is an example of the *jitter2* opcode. It uses the file *jitter2.csd* [examples/jitter2.csd].

### Example 414. Example of the *jitter2* opcode.

# joystick

joystick — Reads data from a joystick controller.

## Description

Reads data from a Linux joystick controller

## Syntax

```
kres joystick kdevice ktab
```

## Performance

### Note

Please note that this opcode is currently only supported on Linux.

*kdevice* -- the index of the joystick device, either /dev/js*N* or /dev/input/js*N*.

*ktab* -- A table to hold input results, should be at least enough elements to store one value for each stick axis and one for each button + 2. The first two elements of the table are initialized with the number of axes and the number of buttons, respectively, when a joystick is opened. If a joystick is unplugged during performance, the opcode will repeatedly attempt to reopen the device with a delay between attempts.

## Examples

Here is an example of the joystick opcode. It uses the file *joystick.csd* [examples/joystick.csd].

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# jspline

jspline — A jitter-spline generator.

## Description

A jitter-spline generator.

## Syntax

```
ares jspline xamp, cpsMin, cpsMax  
kres jspline kamp, cpsMin, cpsMax
```

## Performance

*kres, ares* -- Output signal

*xamp* -- Amplitude factor

*cpsMin, cpsMax* -- Range of point-generation rate. Min and max limits are expressed in cps.

*jspline* (jitter-spline generator) generates a smooth curve based on random points generated at [*cpsMin, cpsMax*] rate. This opcode is similar to *randomi* or *randi* or *jitter*, but segments are not straight lines, but cubic spline curves. Output value range is approximately  $> -xamp$  and  $< xamp$ . Actually, real range could be a bit greater, because of interpolating curves between each pair of random-points.

At present time generated curves are quite smooth when *cpsMin* is not too different from *cpsMax*. When *cpsMin-cpsMax* interval is big, some little discontinuity could occur, but it should not be a problem, in most cases. Maybe the algorithm will be improved in next versions.

These opcodes are often better than *jitter* when user wants to “naturalize” or “analogize” digital sounds. They could be used also in algorithmic composition, to generate smooth random melodic lines when used together with *samphold* opcode.

Note that the result is quite different from the one obtained by filtering white noise, and they allow the user to obtain a much more precise control.

## Examples

Here is an example of the jspline opcode. It uses the file *jspline.csd* [examples/jspline.csd].

### Example 415. Example of the jspline opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# k

k — Converts a i-rate parameter to an k-rate value. Or converts an a-rate value to a k-rate value by down-sampling.

## Description

Converts an i-rate value to control rate, for example to be used with *rnd()* and *birnd()* to generate random numbers at k-rate.

## Syntax

**k(x)** (i-rate args only)

**k(x)** (a-rate args only)

where the argument within the parentheses may be an expression. Value converters perform arithmetic translation from units of one kind to units of another. The result can then be a term in a further expression.

# kgoto

kgoto — Transfer control during the performance-time passes.

## Description

During the p-time passes only, unconditionally transfer control to the statement labeled by *label*.

## Syntax

```
kgoto label
```

where *label* is in the same instrument block and is not an expression.

## Examples

Here is an example of the kgoto opcode. It uses the file *kgoto.csd* [examples/kgoto.csd].

### Example 416. Example of the kgoto opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out   Audio in
-odac          -iadc    ;;;RT audio I/O
; For Non-realtime output leave only the line below:
; -o kgoto.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

; Initialize the global variables.
sr = 44100
kr = 4410
ksmps = 10
nchnls = 1

; Instrument #1.
instr 1
; Change kval linearly from 0 to 2 over
; the period set by the third p-field.
kval line 0, p3, 2
; If kval is greater than or equal to 1 then play the high note.
; If not then play the low note.
if (kval >= 1) kgoto highnote
kgoto lownote

highnote:
kfreq = 880
goto playit

lownote:
kfreq = 440
goto playit

playit:
; Print the values of kval and kfreq.
printks "kval = %f, kfreq = %f\n", 1, kval, kfreq
```

```
a1 oscil 10000, kfreq, 1
  out a1
endin

</CsInstruments>
<CsScore>

; Table #1: a simple sine wave.
f 1 0 32768 10 1

; Play Instrument #1 for two seconds.
i 1 0 2
e

</CsScore>
</CsoundSynthesizer>
```

Its output should include lines like this:

```
kval = 0.000000, kfreq = 440.000000
kval = 0.999732, kfreq = 440.000000
kval = 1.999639, kfreq = 880.000000
```

## See Also

# kr

kr — Sets the control rate.

## Description

These statements are global value *assignments*, made at the beginning of an orchestra, before any instrument block is defined. Their function is to set certain *reserved symbol variables* that are required for performance. Once set, these reserved symbols can be used in expressions anywhere in the orchestra.

## Syntax

```
kr = iarg
```

## Initialization

*kr* = (optional) -- set control rate to *iarg* samples per second. The default value is 4410.

In addition, any *global variable* [55] can be initialized by an *init-time assignment* anywhere before the first *instr statement*. All of the above assignments are run as instrument 0 (i-pass only) at the start of real performance.

Beginning with Csound version 3.46, *kr* can be omitted. Csound will use the default values, or calculate *kr* from defined *ksmps* and *sr*. It is usually better to just specify *ksmps* and *sr* and let csound calculate *kr*.

## Examples

```
sr = 10000
kr = 500
ksmps = 20
g11 = sr/2.
ga init 0
itranspose = octpch(.01)
```

## See Also

*ksmps*, *nchnls*, *nchnls\_i*, *sr*

# ksmps

ksmps — Sets the number of samples in a control period.

## Description

These statements are global value *assignments*, made at the beginning of an orchestra, before any instrument block is defined. Their function is to set certain *reserved symbol variables* that are required for performance. Once set, these reserved symbols can be used in expressions anywhere in the orchestra.

## Syntax

```
ksmps = iarg
```

## Initialization

*ksmps* = (optional) -- set the number of samples in a control period. This value must equal *sr/kr*. The default value is 10.

In addition, any *global variable* [55] can be initialized by an *init-time assignment* anywhere before the first *instr statement*. All of the above assignments are run as instrument 0 (i-pass only) at the start of real performance.

Beginning with Csound version 3.46, either *ksmps* may be omitted. Csound will attempt to calculate the omitted value from the specified *sr* and *kr* values, but it should evaluate to an integer.

### Warning

ksmps must be an integer value.

## Examples

```
sr = 10000
kr = 500
ksmps = 20
gil = sr/2.
ga init 0
itranspose = octpch(.01)
```

## See Also

*kr, nchnls, nchnls\_i, sr*

## Credits

Thanks to a note from Gabriel Maldonado, added a warning about integer values.

# lenarray

lenarray — Evaluates the size or shape length of an array.

## Description

Evaluates the size or number of dimensions of an array.

## Syntax

```
ir lenarray karray[, iwhich]  
  
kr lenarray karray[, iwhich]
```

## Initialisation

*karray* -- The array that is being questioned. It can be of any dimension.

*iwhich* -- selects which dimension to evaluate the size. If zero or negative it selects the number of dimensions. It defaults to 1, as used in a vector.

## Performance

*kr* -- length of vector.

*karray* -- array to query.

If the dimension requested is larger than the actual array, or the array is not initialised the value -1 is returned.

## Examples

Here is an example of the lenarray opcode. It uses the file *lenarray.csd* [examples/lenarray.csd].

### Example 417. Example of the lenarray opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# Ifo

Ifo — A low frequency oscillator of various shapes.

## Description

A low frequency oscillator of various shapes.

## Syntax

```
kres lfo kamp, kcps [, itype]
```

```
ares lfo kamp, kcps [, itype]
```

## Initialization

*itype* (optional, default=0) -- determine the waveform of the oscillator. Default is 0.

- *itype* = 0 - sine
- *itype* = 1 - triangles
- *itype* = 2 - square (bipolar)
- *itype* = 3 - square (unipolar)
- *itype* = 4 - saw-tooth
- *itype* = 5 - saw-tooth(down)

The sine wave is implemented as a 4096 table and linear interpolation. The others are calculated.

## Performance

*kamp* -- amplitude of output

*kcps* -- frequency of oscillator

## Examples

Here is an example of the Ifo opcode. It uses the file *Ifo.csd* [examples/Ifo.csd].

### Example 418. Example of the Ifo opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# limit

`limit` — Sets the lower and upper limits of the value it processes.

## Description

Sets the lower and upper limits of the value it processes.

## Syntax

```
ares limit asig, klow, khigh  
  
ires limit isig, ilow, ihigh  
  
kres limit ksig, klow, khigh
```

## Initialization

*isig* -- input signal

*ilow* -- low threshold

*ihigh* -- high threshold

## Performance

*xsig* -- input signal

*klow* -- low threshold

*khigh* -- high threshold

*limit* sets the lower and upper limits on the *xsig* value it processes. If *xhigh* is lower than *xlow*, then the output will be the average of the two - it will not be affected by *xsig*.

This opcode is useful in several situations, such as table indexing or for clipping and modeling a-rate, i-rate or k-rate signals.

## Examples

Here is an example of the limit opcode. It uses the file *limit.csd* [examples/limit.csd].

### Example 419. Example of the limit opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# line

`line` — Trace a straight line between specified points.

## Description

Trace a straight line between specified points.

## Syntax

```
ares line ia, idur, ib  
  
kres line ia, idur, ib
```

## Initialization

*ia* -- starting value.

*ib* -- value after *idur* seconds.

*idur* -- duration in seconds of segment. A zero or negative value will cause all initialization to be skipped.

## Performance

`line` generates control or audio signals whose values move linearly from an initial value to a final one.

### Note

A common error with this opcode is to assume that the value of *ib* is held after the time *idur*. `line` does not automatically end or stop at the end of the duration given. If your note length is longer than *idur* seconds, `kres` (or `ares`) will not come to rest at *ib*, but will instead continue to rise or fall with the same rate. If a rise (or fall) and then hold is required that the `linseg` opcode should be considered instead.

## Examples

Here is an example of the `line` opcode. It uses the file `line.csd` [examples/line.csd].

### Example 420. Example of the line opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## Credits

# linen

`linen` — Applies a straight line rise and decay pattern to an input amp signal.

## Description

*linen* -- apply a straight line rise and decay pattern to an input amp signal.

## Syntax

```
ares linen xamp, irise, idur, idec
```

```
kres linen kamp, irise, idur, idec
```

## Initialization

*irise* -- rise time in seconds. A zero or negative value signifies no rise modification.

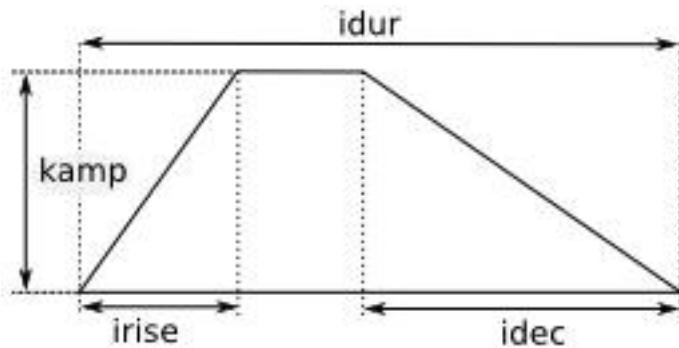

*idur* -- overall duration in seconds. A zero or negative value will cause initialization to be skipped.

*idec* -- decay time in seconds. Zero means no decay. An *idec* > *idur* will cause a truncated decay.

## Performance

*kamp*, *xamp* -- input amplitude signal.

Rise modifications are applied for the first *irise* seconds, and decay from time *idur* - *idec*. If these periods are separated in time there will be a steady state during which *amp* will be unmodified. If *linen* rise and decay periods overlap then both modifications will be in effect for that time. If the overall duration *idur* is exceeded in performance, the final decay will continue on in the same direction, going negative.

Envelope generated by the *linen* opcode

### Note

A common error with this opcode is to assume that the value of 0 is the held after the envelope has finished at *idur*. *linen* does not automatically end or stop at the end of the duration given. If your note length is longer than *idur* seconds, *kres* (or *ares*) will not come to

rest at 0, but will instead continue to fall with the same rate. If a decay and then hold is required then the *linseg* opcode should be considered instead.

## Examples

Here is an example of the *linen* opcode. It uses the file *linen.csd* [examples/linen.csd].

### Example 421. Example of the *linen* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# linenr

linenr — The *linen* opcode extended with a final release segment.

## Description

*linenr* -- same as *linen* except that the final segment is entered only on sensing a MIDI note release. The note is then extended by the decay time.

## Syntax

```
ares linenr xamp, irise, idec, iatdec
```

```
kres linenr kamp, irise, idec, iatdec
```

## Initialization

*irise* -- rise time in seconds. A zero or negative value signifies no rise modification.

*idec* -- decay time in seconds. Zero means no decay. An *idec* > *idur* will cause a truncated decay.

*iatdec* -- attenuation factor by which the closing steady state value is reduced exponentially over the decay period. This value must be positive and is normally of the order of .01. A large or excessively small value is apt to produce a cutoff which is audible. A zero or negative value is illegal.

## Performance

*kamp*, *xamp* -- input amplitude signal.

*linenr* is unique within Csound in containing a *note-off sensor* and *release time extender*. When it senses either a score event termination or a MIDI noteoff, it will immediately extend the performance time of the current instrument by *idec* seconds, then execute an exponential decay towards the factor *iatdec*. For two or more units in an instrument, extension is by the greatest *idec*.

You can use other pre-made envelopes which start a release segment upon receiving a note off message, like *linsegr* and *expsegr*, or you can construct more complex envelopes using *xratim* and *release*. Note that you don't need to use *xratim* if you are using *linenr*, since the time is extended automatically.

These “r” units can also be modified by MIDI noteoff velocities (see *veloffs*).

## Examples

Here is an example of the *linenr* opcode. It uses the file *linenr.csd* [examples/linenr.csd].

### Example 422. Example of the linenr opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# lineto

lineto — Generate glissandos starting from a control signal.

## Description

Generate glissandos starting from a control signal.

## Syntax

```
kres lineto ksig, ktime
```

## Performance

*kres* -- Output signal.

*ksig* -- Input signal.

*ktime* -- Time length of glissando in seconds.

*lineto* adds glissando (i.e. straight lines) to a stepped input signal (for example, produced by *randh* or *lpshold*). It generates a straight line starting from previous step value, reaching the new step value in *ktime* seconds. When the new step value is reached, such value is held until a new step occurs. Be sure that *ktime* argument value is smaller than the time elapsed between two consecutive steps of the original signal, otherwise discontinuities will occur in output signal.

When used together with the output of *lpshold* it emulates the glissando effect of old analog sequencers.

### Note

No new value for *ksig* or *ktime* will have effect until the previous *ktime* has elapsed.

## Examples

Here is an example of the lineto opcode. It uses the file *lineto.csd* [examples/lineto.csd].

### Example 423. Example of the lineto opcode.

# linrand

linrand — Linear distribution random number generator (positive values only).

## Description

Linear distribution random number generator (positive values only). This is an x-class noise generator.

## Syntax

```
ares linrand krang  
  
ires linrand krang  
  
kres linrand krang
```

## Performance

*krange* -- the range of the random numbers (0 - *krange*). Outputs only positive numbers.

For more detailed explanation of these distributions, see:

1. C. Dodge - T.A. Jerse 1985. Computer music. Schirmer books. pp.265 - 286
2. D. Lorrain. A panoply of stochastic cannons. In C. Roads, ed. 1989. Music machine . Cambridge, Massachusetts: MIT press, pp. 351 - 379.

# linseg

linseg — Trace a series of line segments between specified points.

## Description

Trace a series of line segments between specified points.

## Syntax

```
ares linseg ia, idur1, ib [, idur2] [, ic] [...]
```

```
kres linseg ia, idur1, ib [, idur2] [, ic] [...]
```

## Initialization

*ia* -- starting value.

*ib*, *ic*, etc. -- value after *durl* seconds, etc.

*idur1* -- duration in seconds of first segment. A zero or negative value will cause all initialization to be skipped.

*idur2*, *idur3*, etc. -- duration in seconds of subsequent segments. A zero or negative value will terminate the initialization process with the preceding point, permitting the last-defined line or curve to be continued indefinitely in performance. The default is zero.

## Performance

These units generate control or audio signals whose values can pass through 2 or more specified points. The sum of *dur* values may or may not equal the instrument's performance time: a shorter performance will truncate the specified pattern, while a longer one will cause the last value to be repeated until the end of the note.

## Examples

Here is an example of the linseg opcode. It uses the file *linseg.csd* [examples/linseg.csd].

### Example 425. Example of the linseg opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# linsegr

linsegr — Trace a series of line segments between specified points including a release segment.

## Description

Trace a series of line segments between specified points including a release segment.

## Syntax

```
ares linsegr ia, idur1, ib [, idur2] [, ic] [...], irel, iz
```

```
kres linsegr ia, idur1, ib [, idur2] [, ic] [...], irel, iz
```

## Initialization

*ia* -- starting value.

*ib*, *ic*, etc. -- value after *durl* seconds, etc.

*idur1* -- duration in seconds of first segment. A zero or negative value will cause all initialization to be skipped.

*idur2*, *idur3*, etc. -- duration in seconds of subsequent segments. A zero or negative value will terminate the initialization process with the preceding point, permitting the last-defined line or curve to be continued indefinitely in performance. The default is zero.

*irel*, *iz* -- duration in seconds and final value of a note releasing segment.

For Csound versions prior to 5.00, the release time cannot be longer than  $32767/kr$  seconds. This limit has been extended to  $(2^{31}-1)/kr$ .

## Performance

These units generate control or audio signals whose values can pass through 2 or more specified points. The sum of *dur* values may or may not equal the instrument's performance time: a shorter performance will truncate the specified pattern, while a longer one will cause the last-defined segment to continue on in the same direction.

*linsegr* is amongst the Csound “r” units that contain a note-off sensor and release time extender. When each senses an event termination or MIDI noteoff, it immediately extends the performance time of the current instrument by *irel* seconds, and sets out to reach the value *iz* by the end of that period (no matter which segment the unit is in). “r” units can also be modified by MIDI noteoff velocities. For two or more extenders in an instrument, extension is by the greatest period.

You can use other pre-made envelopes which start a release segment upon receiving a note off message, like *linenr* and *expsegr*, or you can construct more complex envelopes using *xratim* and *release*. Note that you don't need to use *xratim* if you are using *linsegr*, since the time is extended automatically.

## Examples

Here is an example of the linsegr opcode. It uses the file *linsegr.csd* [examples/linsegr.csd].

## locsend

locsend — Distributes the audio signals of a previous *locsig* opcode.

## Description

*locsend* depends upon the existence of a previously defined *locsig*. The number of output signals must match the number in the previous *locsig*. The output signals from *locsend* are derived from the values given for distance and reverb in the *locsig* and are ready to be sent to local or global reverb units (see example below). The reverb amount and the balance between the 2 or 4 channels are calculated in the same way as described in the Dodge book (an essential text!).

## Syntax

```
a1, a2 locsend  
  
a1, a2, a3, a4 locsend
```

## Examples

```
asig some audio signal  
kdegree      line    0, p3, 360  
kdistance    line    1, p3, 10  
a1, a2, a3, a4  locsig  asig, kdegree, kdstance, .1  
ar1, ar2, ar3, ar4 locsend  
ga1 = ga1+ar1  
ga2 = ga2+ar2  
ga3 = ga3+ar3  
ga4 = ga4+ar4  
          outq    a1, a2, a3, a4  
endin  
  
instr 99 ; reverb instrument  
a1      reverb2 ga1, 2.5, .5  
a2      reverb2 ga2, 2.5, .5  
a3      reverb2 ga3, 2.5, .5  
a4      reverb2 ga4, 2.5, .5  
          outq    a1, a2, a3, a4  
ga1=0  
ga2=0  
ga3=0  
ga4=0
```

In the above example, the signal, *asig*, is sent around a complete circle once during the duration of a note while at the same time it becomes more and more “distant” from the listeners’ location. *locsig* sends the appropriate amount of the signal internally to *locsend*. The outputs of the *locsend* are added to global accumulators in a common Csound style and the global signals are used as inputs to the reverb units in a separate instrument. For an example, see *locsig*.

*locsig* is useful for quad and stereo panning as well as fixed placed of sounds anywhere between two loudspeakers. Below is an example of the fixed placement of sounds in a stereo field. It uses the file *locsend\_stereo.csd* [examples/locsend\_stereo.csd].

### Example 428. Example of the locsend opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>

# locsig

locsig — Takes an input signal and distributes between 2 or 4 channels.

## Description

*locsig* takes an input signal and distributes it among 2 or 4 channels using values in degrees to calculate the balance between adjacent channels. It also takes arguments for distance (used to attenuate signals that are to sound as if they are some distance further than the loudspeaker itself), and for the amount the signal that will be sent to reverberators. This unit is based upon the example in the Charles Dodge/Thomas Jerse book, *Computer Music*, page 320.

## Syntax

```
a1, a2 locsig asig, kdegree, kdistance, kreverbssend  
a1, a2, a3, a4 locsig asig, kdegree, kdistance, kreverbssend
```

## Performance

*kdegree* -- value between 0 and 360 for placement of the signal in a 2 or 4 channel space configured as: a1=0, a2=90, a3=180, a4=270 (kdegree=45 would balance the signal equally between a1 and a2). *locsig* maps *kdegree* to sin and cos functions to derive the signal balances (e.g.: asig=1, kdegree=45, a1=a2=.707).

*kdistance* -- value  $\geq 1$  used to attenuate the signal and to calculate reverb level to simulate distance cues. As *kdistance* gets larger the sound should get softer and somewhat more reverberant (assuming the use of *locsend* in this case).

*kreverbssend* -- the percentage of the direct signal that will be factored along with the distance and degree values to derive signal amounts that can be sent to a reverb unit such as *reverb*, or *reverb2*.

## Examples

Here is an example of the locsig opcode. It uses the file *locsig\_quad.csd* [examples/locsig\_quad.csd].

### Example 429. Example of the locsig opcode.

# log

`log` — Returns a natural log of a number, or an array (with optional arbitrary base).

## Description

Returns the natural log of  $x$  ( $x$  positive only). In the case of an array input, the operation can have an optional arbitrary base.

The argument value is restricted for `log`, `log10`, and `sqr`.

## Syntax

```
log(x) (no rate restriction)
```

```
kout[ ]log kin[ ][ ,ibas]
```

where the argument within the parentheses may be an expression. Value converters perform arithmetic translation from units of one kind to units of another. The result can then be a term in a further expression. In the case of an array input, ibas is the optional arbitrary base, which defaults to e (natural log base).

## Examples

Here is an example of the `log` opcode. It uses the file `log.csd` [examples/log.csd].

### Example 430. Example of the log opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# log10

`log10` — Returns a base 10 log.

## Description

Returns the base 10 log of  $x$  ( $x$  positive only).

The argument value is restricted for `log`, `log10`, and `sqrt`.

## Syntax

```
log10(x) (no rate restriction)
```

where the argument within the parentheses may be an expression. Value converters perform arithmetic translation from units of one kind to units of another. The result can then be a term in a further expression.

## Examples

Here is an example of the `log10` opcode. It uses the file `log10.csd` [examples/log10.csd].

### Example 431. Example of the log10 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>

# log2

`log2` — Returns a base 2 log.

## Description

Returns the base 2 log of  $x$  ( $x$  positive only).

The argument value is restricted for `log`, `log2`, and `sqrt`.

## Syntax

```
log2(x) (no rate restriction)
```

where the argument within the parentheses may be an expression. Value converters perform arithmetic translation from units of one kind to units of another. The result can then be a term in a further expression.

## Examples

Here is an example of the `log2` opcode. It uses the file `log2.csd` [examples/log2.csd].

# logbtwo

logbtwo — Performs a logarithmic base two calculation.

## Description

Performs a logarithmic base two calculation.

## Syntax

```
logbtwo(x)  (init-rate or control-rate args only)
```

## Performance

*logbtwo()* returns the logarithm base two of *x*. The range of values admitted as argument is .25 to 4 (i.e. from -2 octave to +2 octave response). This function is the inverse of *powoftwo()*.

These functions are fast, because they read values stored in tables. Also they are very useful when working with tuning ratios. They work at i- and k-rate.

## Examples

Here is an example of the logbtwo opcode. It uses the file *logbtwo.csd* [examples/logbtwo.csd].

### Example 433. Example of the logbtwo opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>

# logcurve

logcurve — This opcode implements a formula for generating a normalised logarithmic curve in range 0 - 1. It is based on the Max / MSP work of Eric Singer (c) 1994.

## Description

Generates a logarithmic curve in range 0 to 1 of arbitrary steepness. Steepness index equal to or lower than 1.0 will result in Not-a-Number errors and cause unstable behavior.

The formula used to calculate the curve is:

```
log(x * (y-1)+1) / (log(y))
```

where x is equal to *kindex* and y is equal to *ksteepness*.

## Syntax

```
kout logcurve kindex, ksteepness
```

## Performance

*kindex* -- Index value. Expected range 0 to 1.

*ksteepness* -- Steepness of the generated curve. Values closer to 1.0 result in a straighter line while larger values steepen the curve.

*kout* -- Scaled output.

## Examples

Here is an example of the logcurve opcode. It uses the file *logcurve.csd* [examples/logcurve.csd].

### Example 434. Example of the logcurve opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# loop\_ge

loop\_ge — Looping constructions.

## Description

Construction of looping operations.

## Syntax

```
loop_ge  indx, idecr, imin, label  
  
loop_ge  kndx, kdecr, kmin, label
```

## Initialization

*indx* -- i-rate variable to count loop.

*idecr* -- value to decrement the loop.

*imin* -- minimum value of loop index.

## Performance

*kndx* -- k-rate variable to count loop.

*kdecr* -- value to decrement the loop.

*kmin* -- minimum value of loop index.

The actions of **loop\_ge** are equivalent to the code

```
indx = indx - idecr  
if (indx >= imin) igoto label
```

or

```
kndx = kndx - kdecr  
if (kndx >= kmin) kgoto label
```

## See Also

# loop\_le

loop\_le — Looping constructions.

## Description

Construction of looping operations.

## Syntax

```
loop_le  indx, incr, imax, label
```

```
loop_le  kndx, kncr, kmax, label
```

## Initialization

*indx* -- i-rate variable to count loop.

*incr* -- value to increment the loop.

*imax* -- maximum value of loop index.

## Performance

*kndx* -- k-rate variable to count loop.

*kncre* -- value to increment the loop.

*kmax* -- maximum value of loop index.

The actions of **loop\_le** are equivalent to the code

```
indx = indx + incr  
if (indx <= imax) igoto label
```

or

```
kndx = kndx + kncre  
if (kndx <= kmax) kgoto label
```

## Examples

# loop\_lt

loop\_lt — Looping constructions.

## Description

Construction of looping operations.

## Syntax

```
loop_lt  indx, incr, imax, label  
  
loop_lt  kndx, kncr, kmax, label
```

## Initialization

*indx* -- i-rate variable to count loop.

*incr* -- value to increment the loop.

*imax* -- maximum value of loop index.

## Performance

*kndx* -- k-rate variable to count loop.

*kncre* -- value to increment the loop.

*kmax* -- maximum value of loop index.

The actions of **loop\_lt** are equivalent to the code

```
indx = indx + incr  
if (indx < imax) igoto label
```

or

```
kndx = kndx + kncre  
if (kndx < kmax) kgoto label
```

## Examples

Here is an example of the `loop_lt` opcode. It uses the file `loop_lt.csd` [examples/loop\_lt.csd].

### Example 436. Example of the `loop_lt` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# loopseg

loopseg — Generate control signal consisting of linear segments delimited by two or more specified points.

## Description

Generate control signal consisting of linear segments delimited by two or more specified points. The entire envelope is looped at *kfreq* rate. Each parameter can be varied at k-rate.

## Syntax

```
ksig loopseg kfreq, ktrig, iphase, kvalue0, ktime0 [, kvalue1] [, ktime1] \
[, kvalue2] [, ktime2][...]
```

## Initialization

*iphase* -- A value between 0 and 1 to say where to start the loop. Zero, the commonest value, indicates the beginning.

## Performance

*ksig* -- Output signal.

*kfreq* -- Repeat rate in Hz or fraction of Hz.

*ktrig* -- If non-zero, retriggers the envelope from start (see *trigger opcode*), before the envelope cycle is completed.

*kvalue0*...*kvalueN* -- Values of points

*ktime0*...*ktimeN* -- Times between points; expressed in fractions of a cycle (see below). The final time designates a ramp between the final value and the first value.

*loopseg* opcode is similar to *linseg*, but the entire envelope is looped at *kfreq* rate. Notice that times are not expressed in seconds but in fraction of a cycle. Actually each duration represent is proportional to the other, and the entire cycle duration is proportional to the sum of all duration values.

The sum of all duration is then rescaled according to *kfreq* argument. For example, considering an envelope made up of 3 segments, each segment having 100 as duration value, their sum will be 300. This value represents the total duration of the envelope, and is actually divided into 3 equal parts, a part for each segment.

Actually, the real envelope duration in seconds is determined by *kfreq*. Again, if the envelope is made up of 3 segments, but this time the first and last segments have a duration of 50, whereas the central segment has a duration of 100 again, their sum will be 200. This time 200 represent the total duration of the 3 segments, so the central segment will be twice as long as the other segments.

All parameters can be varied at k-rate. Negative frequency values are allowed, reading the envelope backward. *ktime0* should always be set to 0, except if the user wants some special effect.

## Examples

Here is an example of the loopseg opcode. It uses the file *loopseg.csd* [examples/loopseg.csd].

### Example 437. Example of the loopseg opcode.

# loopsegp

loopsegp — Control signals based on linear segments.

## Description

Generate control signal consisting of linear segments delimited by two or more specified points. The entire envelope can be looped at time-variant rate. Each segment coordinate can also be varied at k-rate.

## Syntax

```
ksig loopsegp kphase, kvalue0, kdur0, kvalue1 \
[, kdur1, ... , kdurN-1, kvalueN]
```

## Performance

*ksig* - output signal

*kphase* - point of the sequence read, expressed as a fraction of a cycle (0 to 1)

*kvalue0* ...*kvalueN* - values of points

*kdur0* ...*kdurN-1* - duration of points expressed in fraction of a cycle

*loopsegp* opcode is similar to *loopseg*; the only difference is that, instead of frequency, a time-variant phase is required. If you use *phasor* to get the phase value, you will have a behaviour identical to *loopseg*, but interesting results can be achieved when using phases having non-linear motions, making *loopsegp* more powerful and general than *loopseg*.

## Examples

Here is an example of the *loopsegp* opcode. It uses the file *loopsegp.csd* [examples/loopsegp.csd].

# looptseg

looptseg — Generate control signal consisting of exponential or linear segments delimited by two or more specified points.

## Description

Generate control signal consisting of controllable exponential segments or linear segments delimited by two or more specified points. The entire envelope is looped at *kfreq* rate. Each parameter can be varied at k-rate.

## Syntax

```
ksig looptseg kfreq, ktrig, iphase, kvalue0, ktype0, ktime0, [, kvalue1] [, ktype1] [, ktime1] \
[, kvalue2] [, ktype2] [, ktime2] [...] [, kvalueN] [, ktypeN] [, ktimeN]
```

## Initialization

*iphase* -- A value between 0 and 1 to say where to start the loop. Zero, the commonest value, indicates the beginning.

## Performance

*ksig* -- Output signal.

*kfreq* -- Repeat rate in Hz or fraction of Hz.

*ktrig* -- If non-zero, retriggers the envelope from start (see *trigger opcode*), before the envelope cycle is completed.

*kvalue0*...*kvalueN* -- Values of points

*ktime0*...*ktimeN* -- Times between points; expressed in fractions of a cycle (see below). The final time designates a ramp between the final value and the first value.

*ktype0*...*ktypeN* -- shape of the envelope. If the value is 0 then the shape is linear; otherwise it is an concave exponential (positive type) or a convex exponential (negative type).

*looptseg* opcode is similar to *transeg*, but the entire envelope is looped at *kfreq* rate. Notice that times are not expressed in seconds but in fraction of a cycle. Actually each duration represent is proportional to the other, and the entire cycle duration is proportional to the sum of all duration values.

The sum of all duration is then rescaled according to *kfreq* argument. For example, considering an envelope made up of 3 segments, each segment having 100 as duration value, their sum will be 300. This value represents the total duration of the envelope, and is actually divided into 3 equal parts, a part for each segment.

Actually, the real envelope duration in seconds is determined by *kfreq*. Again, if the envelope is made up of 3 segments, but this time the first and last segments have a duration of 50, whereas the central segment has a duration of 100 again, their sum will be 200. This time 200 represent the total duration of the 3 segments, so the central segment will be twice as long as the other segments.

All parameters can be varied at k-rate. Negative frequency values are allowed, reading the envelope

backward. *ktime0* should always be set to 0, except if the user wants some special effect.

## Examples

Here is an example of the lopptseg opcode. It uses the file *looptseg.csd* [examples/looptseg.csd].

# loopxseg

loopxseg — Generate control signal consisting of exponential segments delimited by two or more specified points.

## Description

Generate control signal consisting of exponential segments delimited by two or more specified points. The entire envelope is looped at *kfreq* rate. Each parameter can be varied at k-rate.

## Syntax

```
ksig loopxseg kfreq, ktrig, iphase, ktime0, kvalue0 [, ktime1] [, kvalue1] \
[, ktime2] [, kvalue2] [...]
```

## Performance

*ksig* -- Output signal.

*kfreq* -- Repeat rate in Hz or fraction of Hz.

*ktrig* -- If non-zero, retriggers the envelope from start (see *trigger opcode*), before the envelope cycle is completed.

*iphase* -- A value between 0 and 1 to say where to start the loop. Zero, the commonest value, indicates the beginning.

*ktime0...ktimeN* -- Times of points; expressed in fraction of a cycle.

*kvalue0...kvalueN* -- Values of points

*loopxseg* opcode is similar to *expseg*, but the entire envelope is looped at *kfreq* rate. Notice that times are not expressed in seconds but in fraction of a cycle. Actually each duration represent is proportional to the other, and the entire cycle duration is proportional to the sum of all duration values.

The sum of all duration is then rescaled according to *kfreq* argument. For example, considering an envelope made up of 3 segments, each segment having 100 as duration value, their sum will be 300. This value represents the total duration of the envelope, and is actually divided into 3 equal parts, a part for each segment.

Actually, the real envelope duration in seconds is determined by *kfreq*. Again, if the envelope is made up of 3 segments, but this time the first and last segments have a duration of 50, whereas the central segment has a duration of 100 again, their sum will be 200. This time 200 represent the total duration of the 3 segments, so the central segment will be twice as long as the other segments.

All parameters can be varied at k-rate. Negative frequency values are allowed, reading the envelope backward. *ktime0* should always be set to 0, except if the user wants some special effect.

# lorenz

**lorenz** — Implements the Lorenz system of equations.

## Description

Implements the Lorenz system of equations. The Lorenz system is a chaotic-dynamic system which was originally used to simulate the motion of a particle in convection currents and simplified weather systems. Small differences in initial conditions rapidly lead to diverging values. This is sometimes expressed as the butterfly effect. If a butterfly flaps its wings in Australia, it will have an effect on the weather in Alaska. This system is one of the milestones in the development of chaos theory. It is useful as a chaotic audio source or as a low frequency modulation source.

## Syntax

```
ax, ay, az lorenz ksv, krv, kbv, kh, ix, iy, iz, iskip [, iskipinit]
```

## Initialization

*ix, iy, iz* -- the initial coordinates of the particle.

*iskip* -- used to skip generated values. If *iskip* is set to 5, only every fifth value generated is output. This is useful in generating higher pitched tones.

*iskipinit* (optional, default=0) -- if non zero skip the initialisation of the filter. (New in Csound version 4.23f13 and 5.0)

## Performance

*ksv* -- the Prandtl number or sigma

*krv* -- the Rayleigh number

*kbv* -- the ratio of the length and width of the box in which the convection currents are generated

*kh* -- the step size used in approximating the differential equation. This can be used to control the pitch of the systems. Values of .1-.001 are typical.

The equations are approximated as follows:

$$\begin{aligned}x &= x + h * (s * (y - x)) \\y &= y + h * (-x * z + r * x - y) \\z &= z + h * (x * y - b * z)\end{aligned}$$

The historical values of these parameters are:

ks = 10  
kr = 28  
kb = 8/3

## Note

This algorithm uses internal non linear feedback loops which causes audio result to depend on the orchestra sampling rate. For example, if you develop a project with *sr*=48000Hz and if you want to produce an audio CD from it, you should record a file with *sr*=48000Hz and then downsample the file to 44100Hz using the *srconv* utility.

# Examples

Here is an example of the lorenz opcode. It uses the file *lorenz.csd* [examples/lorenz.csd].

# lorisread

lorisread — Imports a set of bandwidth-enhanced partials from a SDIF-format data file, applying control-rate frequency, amplitude, and bandwidth scaling envelopes, and stores the modified partials in memory.

## Syntax

```
lorisread ktmpnt, ifilcod, istoreidx, kfreqenv, kampenv, kbwenv[, ifadetime]
```

## Description

lorisread imports a set of bandwidth-enhanced partials from a SDIF-format data file, applying control-rate frequency, amplitude, and bandwidth scaling envelopes, and stores the modified partials in memory.

## Initialization

*ofilcod* - integer or character-string denoting a control-file derived from reassigned bandwidth-enhanced analysis of an audio signal. An integer denotes the suffix of a file loris.sdif (e.g. loris.sdif.1); a character-string (in double quotes) gives a filename, optionally a full pathname. If not a full pathname, the file is sought first in the current directory, then in the one given by the environment variable SADIR (if defined). The reassigned bandwidth-enhanced data file contains breakpoint frequency, amplitude, noisiness, and phase envelope values organized for bandwidth-enhanced additive resynthesis. The control data must conform to one of the SDIF formats that can be

Loris stores partials in SDIF RBEP frames. Each RBEP frame contains one RBEP matrix, and each row in a RBEP matrix describes one breakpoint in a Loris partial. A RBEL frame containing one RBEL matrix describing the labeling of the partials may precede the first RBEP frame in the SDIF file. The RBEP and RBEL frame and matrix definitions are included in the SDIF file's header. In addition to RBEP frames, Loris can also read and write SDIF 1TRC frames. Since 1TRC frames do not represent bandwidth-enhancement or the exact timing of Loris breakpoints, their use is not recommended. 1TRC capabilities are provided to allow interchange with programs that are unable to handle RBEP frames.

*istoreidx*, *ireadidx*, *isrcidx*, *itgtidx* are labels that identify a stored set of bandwidth-enhanced partials. lorisread imports partials from a SDIF file and stores them with the integer label *istoreidx*. lorismorph morphs sets of partials labeled *isrcidx* and *itgtidx*, and stores the resulting partials with the integer label *istoreidx*. lorisplay renders the partials stored with the label *ireadidx*. The labels are used only at initialization time, and may be reused without any cost or benefit in efficiency, and without introducing any interaction between instruments or instances.

*ifadetime* (*optional*) - In general, partials exported from Loris begin and end at non-zero amplitude. In order to prevent artifacts, it is very often necessary to fade the partials in and out, instead of turning them abruptly on and off. Specification of a non-zero ifadetime causes partials to fade in at their onsets and to fade out at their terminations. This is achieved by adding two more breakpoints to each partial: one ifadetime seconds before the start time and another ifadetime seconds after the end time. (However, no breakpoint will be introduced at a time less than zero. If necessary, the onset fade time will be shortened.) The additional breakpoints at the partial onset and termination will have the same frequency and bandwidth as the first and last breakpoints in the partial, respectively, but their amplitudes will be zero. The phase of the new breakpoints will be extrapolated to preserve phase correctness. If no value is specified, ifadetime defaults to zero. Note that the fadetime may not be exact, since the partial parameter envelopes are sampled at the control rate (krate) and indexed by ktmpnt (see below), and not by real time.

# Performance

lorisread reads pre-computed Reassigned Bandwidth-Enhanced analysis data from a file stored in SDIF format, as described above. The passage of time through this file is specified by ktimpnt, which represents the time in seconds. ktimpnt must always be positive, but can move forwards or backwards in time, be stationary or discontinuous, as a pointer into the analysis file. kfreqenv is a control-rate transposition factor: a value of 1 incurs no transposition, 1.5 transposes up a perfect fifth, and .5 down an octave. kampenv is a control-rate scale factor that is applied to all partial amplitude envelopes. kbwenv is a control-rate scale factor that is applied to all partial bandwidth or noisiness envelopes. The bandwidth-enhanced partial data is stored in memory with a specified label for future access by another generator.

## Examples

Here is an example of the lorisread opcode. It uses the file *lorisread.csd* [examples/lorisread.csd].

### Example 442. Example of the lorisread opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## Credits

This implementation of the Loris unit generators was written by Kelly Fitz ([loris@cerlsoundgroup.org](mailto:loris@cerlsoundgroup.org) [<mailto:loris@cerlsoundgroup.org>]). It is patterned after a prototype implementation of the *lorisplay* unit generator written by Corbin Champion, and based on the method of Bandwidth-Enhanced Additive Synthesis and on the sound morphing algorithms implemented in the Loris library for sound modeling and manipulation. The opcodes were further adapted as a plugin for Csound 5 by Michael Gogins.

# lorismorph

**lorismorph** — Morphs two stored sets of bandwidth-enhanced partials and stores a new set of partials representing the morphed sound. The morph is performed by linearly interpolating the parameter envelopes (frequency, amplitude, and bandwidth, or noisiness) of the bandwidth-enhanced partials according to control-rate frequency, amplitude, and bandwidth morphing functions.

## Syntax

```
lorismorph isrcidx, itgtidx, istoreidx, kfreqmorphenv, kampmorphenv, kbwmorphenv
```

## Description

*lorismorph* morphs two stored sets of bandwidth-enhanced partials and stores a new set of partials representing the morphed sound. The morph is performed by linearly interpolating the parameter envelopes (frequency, amplitude, and bandwidth, or noisiness) of the bandwidth-enhanced partials according to control-rate frequency, amplitude, and bandwidth morphing functions.

## Initialization

*istoreidx*, *ireadidx*, *isrcidx*, *itgtidx* are labels that identify a stored set of bandwidth-enhanced partials. *lorisread* imports partials from a SDIF file and stores them with the integer label *istoreidx*. *lorismorph* morphs sets of partials labeled *isrcidx* and *itgtidx*, and stores the resulting partials with the integer label *istoreidx*. *lorisplay* renders the partials stored with the label *ireadidx*. The labels are used only at initialization time, and may be reused without any cost or benefit in efficiency, and without introducing any interaction between instruments or instances.

## Performance

*lorismorph* generates a set of bandwidth-enhanced partials by morphing two stored sets of partials, the source and target partials, which may have been imported using *lorisread*, or generated by another unit generator, including another instance of *lorismorph*. The morph is performed by interpolating the parameters of corresponding (labeled) partials in the two source sounds. The sound morph is described by three control-rate morphing envelopes. *kfreqmorphenv* describes the interpolation of partial frequency values in the two source sounds. When *kfreqmorphenv* is 0, partial frequencies are obtained from the partials stored at *isrcidx*. When *kfreqmorphenv* is 1, partial frequencies are obtained from the partials at *itgtidx*. When *kfreqmorphenv* is between 0 and 1, the partial frequencies are interpolated between corresponding source and target partials. Interpolation of partial amplitudes and bandwidth (noisiness) coefficients are similarly described by *kampmorphenv* and *kbwmorphenv*.

## Examples

Here is an example of the *lorismorph* opcode. It uses the file *lorismorph.csd* [examples/lorismorph.csd].

### Example 443. Example of the lorismorph opcode.

# lorisplay

*lorisplay* — renders a stored set of bandwidth-enhanced partials using the method of Bandwidth-Enhanced Additive Synthesis implemented in the Loris software, applying control-rate frequency, amplitude, and bandwidth scaling envelopes.

## Syntax

```
ar lorisplay ireadidx, kfreqenv, kampenv, kbwenv
```

## Description

*lorisplay* renders a stored set of bandwidth-enhanced partials using the method of Bandwidth-Enhanced Additive Synthesis implemented in the Loris software, applying control-rate frequency, amplitude, and bandwidth scaling envelopes.

## Initialization

*istoreidx*, *ireadidx*, *isrcidx*, *itgtidx* are labels that identify a stored set of bandwidth-enhanced partials. *lorisread* imports partials from a SDIF file and stores them with the integer label *istoreidx*. *lorismorph* morphs sets of partials labeled *isrcidx* and *itgtidx*, and stores the resulting partials with the integer label *istoreidx*. *lorisplay* renders the partials stored with the label *ireadidx*. The labels are used only at initialization time, and may be reused without any cost or benefit in efficiency, and without introducing any interaction between instruments or instances.

## Performance

*lorisplay* implements signal reconstruction using Bandwidth-Enhanced Additive Synthesis. The control data is obtained from a stored set of bandwidth-enhanced partials imported from an SDIF file using *lorisread* or constructed by another unit generator such as *lorismorph*. *kfreqenv* is a control-rate transposition factor: a value of 1 incurs no transposition, 1.5 transposes up a perfect fifth, and .5 down an octave. *kampenv* is a control-rate scale factor that is applied to all partial amplitude envelopes. *kbwenv* is a control-rate scale factor that is applied to all partial bandwidth or noisiness envelopes. The bandwidth-enhanced partial data is stored in memory with a specified label for future access by another generator.

## Examples

# loscil

loscil — Read sampled sound from a table.

## Description

Read sampled sound (mono or stereo) from a table, with optional sustain and release looping.

## Syntax

```
ar1 [,ar2] loscil xamp, kcps, ifn [, ibas] [, imod1] [, ibeg1] [, iend1] \
[, imod2] [, ibeg2] [, iend2]
```

## Initialization

*ifn* -- function table number, typically denoting an sampled sound segment with prescribed looping points loaded using *GEN01*. The source file may be mono or stereo.

*ibas* (optional) -- base frequency in *Hz* of the recorded sound. This optionally overrides the frequency given in the audio file, but is required if the file did not contain one. The default value is 261.626 Hz, i.e. middle C. (New in Csound 4.03). If this value is not known or not present, use 1 here and in *kcps*.

*imod1, imod2* (optional, default=-1) -- play modes for the sustain and release loops. A value of 1 denotes normal looping, 2 denotes forward & backward looping, 0 denotes no looping. The default value (-1) will defer to the mode and the looping points given in the source file. Make sure you select an appropriate mode if the file does not contain this information.

*ibeg1, iend1, ibeg2, iend2* (optional, dependent on *mod1, mod2*) -- begin and end points of the sustain and release loops. These are measured in *sample frames* from the beginning of the file, so will look the same whether the sound segment is monaural or stereo. If no loop points are specified, and a looping mode (*imod1, imod2*) is given, the file will be looped for the whole length.

## Performance

*ar1, ar2* -- the output at audio-rate. There is just *ar1* for mono output. However, there is both *ar1* and *ar2* for stereo output.

*xamp* -- the amplitude of the output signal.

*kcps* -- the frequency of the output signal in cycles per second.

*loscil* samples the ftable audio at a rate determined by *kcps*, then multiplies the result by *xamp*. The sampling increment for *kcps* is dependent on the table's base-note frequency *ibas*, and is automatically adjusted if the orchestra *sr* value differs from that at which the source was recorded. In this unit, ftable is always sampled with interpolation.

If sampling reaches the *sustain loop* endpoint and looping is in effect, the point of sampling will be modified and *loscil* will continue reading from within that loop segment. Once the instrument has received a *turnoff* signal (from the score or from a MIDI noteoff event), the next sustain endpoint encountered will be ignored and sampling will continue towards the *release loop* end-point, or towards the last sample (henceforth to zeros).

*loscil* is the basic unit for building a sampling synthesizer. Given a sufficient set of recorded piano tones,

for example, this unit can resample them to simulate the missing tones. Locating the sound source nearest a desired pitch can be done via table lookup. Once a sampling instrument has begun, its *turnoff* point may be unpredictable and require an external *release* envelope; this is often done by gating the sampled audio with *linenr*, which will extend the duration of a turned-off instrument by a specific period while it implements a decay.

If you want to loop the whole file, specify a looping mode in *imod1* and do not enter any values for *ibeg* and *iend*.

## Note to Windows users

Windows users typically use back-slashes, “\”, when specifying the paths of their files. As an example, a Windows user might use the path “c:\music\samples\loop001.wav”. This is problematic because back-slashes are normally used to specify special characters.

To correctly specify this path in Csound, one may alternately:

- *Use forward slashes*: c:/music/samples/loop001.wav
- *Use back-slash special characters*, “\\”: c:\\music\\\\samples\\\\loop001.wav

## Note

This is mono *loscil*:

```
a1 loscil 10000, 1, 1, 1 ,1
```

...and this is stereo *loscil*:

```
a1, a2 loscil 10000, 1, 1, 1 ,1
```

## Examples

Here is an example of the *loscil* opcode. It uses the files *loscil.csd* [examples/loscil.csd], *mary.wav* [examples/mary.wav] and *kickroll.wav* [examples/kickroll.wav].

### Example 445. Example of the loscil opcode.

# loscil3

loscil3 — Read sampled sound from a table using cubic interpolation.

## Description

Read sampled sound (mono or stereo) from a table, with optional sustain and release looping, using cubic interpolation.

## Syntax

```
ar1 [,ar2] loscil3 xamp, kcps, ifn [, ibas] [, imod1] [, ibeg1] [, iend1] \
[, imod2] [, ibeg2] [, iend2]
```

## Initialization

*ifn* -- function table number, typically denoting an sampled sound segment with prescribed looping points loaded using *GEN01*. The source file may be mono or stereo.

*ibas* (optional) -- base frequency in Hz of the recorded sound. This optionally overrides the frequency given in the audio file, but is required if the file did not contain one. The default value is 261.626 Hz, i.e. middle C. (New in Csound 4.03). If this value is not known or not present, use 1 here and in *kcps*.

*imod1, imod2* (optional, default=-1) -- play modes for the sustain and release loops. A value of 1 denotes normal looping, 2 denotes forward & backward looping, 0 denotes no looping. The default value (-1) will defer to the mode and the looping points given in the source file. Make sure you select an appropriate mode if the file does not contain this information.

*ibeg1, iend1, ibeg2, iend2* (optional, dependent on *mod1, mod2*) -- begin and end points of the sustain and release loops. These are measured in *sample frames* from the beginning of the file, so will look the same whether the sound segment is monaural or stereo. If no loop points are specified, and a looping mode (*imod1, imod2*) is given, the file will be looped for the whole length.

## Performance

*ar1, ar2* -- the output at audio-rate. There is just *ar1* for mono output. However, there is both *ar1* and *ar2* for stereo output.

*xamp* -- the amplitude of the output signal.

*kcps* -- the frequency of the output signal in cycles per second.

*loscil3* is identical to *loscil* except that it uses cubic interpolation. New in Csound version 3.50.

### Note to Windows users

Windows users typically use back-slashes, “\”, when specifying the paths of their files. As an example, a Windows user might use the path “c:\music\samples\loop001.wav”. This is problematic because back-slashes are normally used to specify special characters.

To correctly specify this path in Csound, one may alternately:

- Use forward slashes: c:/music/samples/loop001.wav
- Use back-slash special characters, “\\”: c:\\music\\samples\\loop001.wav

## Note

This is mono loscil3:

```
a1 loscil3 10000, 1, 1, 1, 1
```

...and this is stereo loscil3:

```
a1, a2 loscil3 10000, 1, 1, 1, 1
```

# Examples

Here is an example of the loscil3 opcode. It uses the file *loscil3.csd* [examples/loscil3.csd], *mary.wav* [examples/mary.wav] and *kickroll.wav* [examples/kickroll.wav].

### Example 446. Example of the loscil3 opcode.

# loscilx

loscilx — Read multi-channel sampled sound from a table.

## Description

Read sampled sound (up to 16 channels) from a table, with optional sustain and release looping.

## Syntax

```
ar1 [, ar2, ar3, ar4, ar5, ar6, ar7, ar8, ar9, ar10, ar11, ar12, ar13, ar14, \
      ar15, ar16] loscilx xamp, kcps, ifn \
[, iwsiz, ibas, istrat, imod, ibeg, iend]
```

## Initialization

*ifn* -- function table number, typically denoting a sampled sound segment with prescribed looping points loaded using *GEN01*. The source file may have up to 16 channels.

*iwsiz* (optional) -- window size used in interpolation. *iwsiz* (optional, defaults to zero) -- interpolation window size, in samples. Can be one of the following:

- 1: round to nearest sample (no interpolation, for *kpitch*=1)
- 2: linear interpolation
- 4: cubic interpolation
- >= 8: *iwsiz* point sinc interpolation with anti-aliasing (slow)

Zero or negative values select the default, which is cubic interpolation.

*ibas* (optional) -- base frequency in Hz of the recorded sound. This optionally overrides the frequency given in the audio file, but is required if the file did not contain one. The default value is 261.626 Hz, i.e. middle C. (New in Csound 4.03). If this value is not known or not present, use 1 here and in *kcps*.

*istrat* (optional, default 0) -- Frame to start reading the data. If this is not an integer the the data is interpolated (see *iwsiz*).

*imod* (optional, default -1) -- play mode for the sustain and release loops. A value of 1 denotes normal looping, 2 denotes forward & backward looping, 0 denotes no looping. The default value (-1) will defer to the mode and the looping points given in the source file. Make sure you select an appropriate mode if the file does not contain this information.

*ibeg*, *iend* (optional, depending on *imod*) -- begin and end points of the sustain and release loops. These are measured in *sample frames* from the beginning of the file. If no loop points are specified, and a looping mode (*imod* is given), the file will be looped for the whole length.

## Performance

*ar1, ar2, ...* -- the output at audio-rate. The number of outputs must match the number of channels in the sample file.

*xamp* -- the amplitude of the output signal.

*kcps* -- the factor to read the file. For example, a value of 1 has no pitch change, 1.5 is up a fifth and 2 an octave.

*loscilx* samples the ftable audio at a rate determined by *kcps*, then multiplies the result by *xamp*. The sampling increment for *kcps* is dependent on the table's base-note frequency *ibas*, and is automatically adjusted if the orchestra *sr* value differs from that at which the source was recorded. In this unit, ftable is always sampled with interpolation.

If sampling reaches the *sustain loop* endpoint and looping is in effect, the point of sampling will be modified and *loscil* will continue reading from within that loop segment. Once the instrument has received a *turnoff* signal (from the score or from a MIDI noteoff event), the next sustain endpoint encountered will be ignored and sampling will continue towards the *release loop* end-point, or towards the last sample (henceforth to zeros).

If you want to loop the whole file, specify a looping mode in *imod* and do not enter any values for *ibeg* and *iend*.

## Examples

Here is an example of the *loscilx* opcode. It uses the files *loscil.csd* [examples/loscil.csd] and *kickroll.wav* [examples/kickroll.wav].

### Example 447. Example of the loscilx opcode.

# lowpass2

lowpass2 — A resonant lowpass filter.

## Description

Implementation of a resonant second-order lowpass filter.

## Syntax

```
ares lowpass2 asig, kcf, kq [, iskip]
```

## Initialization

*iskip* -- initial disposition of internal data space. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*asig* -- input signal to be filtered

*kcf* -- cutoff or resonant frequency of the filter, measured in Hz

*kq* -- Q of the filter, defined, for bandpass filters, as bandwidth/cutoff. *kq* should be between 1 and 500

*lowpass2* is a second order IIR lowpass filter, with k-rate controls for cutoff frequency (*kcf*) and Q (*kq*). As *kq* is increased, a resonant peak forms around the cutoff frequency, transforming the lowpass filter response into a response that is similar to a bandpass filter, but with more low frequency energy. This corresponds to an increase in the magnitude and "sharpness" of the resonant peak. For high values of *kq*, a scaling function such as *balance* may be required. In practice, this allows for the simulation of the voltage-controlled filters of analog synthesizers, or for the creation of a pitch of constant amplitude while filtering white noise.

## Examples

Here is an example of the lowpass2 opcode. It uses the file *lowpass2.csd* [examples/lowpass2.csd].

# lowres

*lowres* — Another resonant lowpass filter.

## Description

*lowres* is a resonant lowpass filter.

## Syntax

```
ares lowres asig, kcutoff, kresonance [, iskip]
```

## Initialization

*iskip* -- initial disposition of internal data space. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*asig* -- input signal

*kcutoff* -- filter cutoff frequency point

*kresonance* -- resonance amount

*lowres* is a resonant lowpass filter derived from a Hans Mikelson orchestra. This implementation is much faster than implementing it in Csound language, and it allows *kr* lower than *sr*. *kcutoff* is not in Hz and *kresonance* is not in dB, so experiment for the finding best results.

## Examples

Here is an example of the *lowres* opcode. It uses the file *lowres.csd* [examples/lowres.csd].

### Example 449. Example of the *lowres* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# lowresx

`lowresx` — Simulates layers of serially connected resonant lowpass filters.

## Description

`lowresx` is equivalent to more layers of `lowres` with the same arguments serially connected.

## Syntax

```
ares lowresx asig, xcutoff, xresonance [, inumlayer] [, iskip]
```

## Initialization

`inumlayer` -- number of elements in a `lowresx` stack. Default value is 4. There is no maximum.

`iskip` -- initial disposition of internal data space. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

`asig` -- input signal

`xcutoff` -- filter cutoff frequency point

`xresonance` -- resonance amount

`lowresx` is equivalent to more layer of `lowres` with the same arguments serially connected. Using a stack of a larger number of filters allows a sharper cutoff. This is faster than using a larger number of instances of `lowres` in a Csound orchestra because only one initialization and k cycle are needed at time and the audio loop falls entirely inside the cache memory of processor. Based on an orchestra by Hans Mikelson

## Examples

Here is an example of the `lowresx` opcode. It uses the file `lowresx.csd` [examples/lowresx.csd].

### Example 450. Example of the `lowresx` opcode.

# lpf18

lpf18 — A 3-pole sweepable resonant lowpass filter.

## Description

Implementation of a 3 pole sweepable resonant lowpass filter.

## Syntax

```
ares lpf18 asig, xfco, xres, xdist [, iskip]
```

## Initialization

*iskip* (optional, default=0) -- Skip initialization if present and non-zero.

## Performance

*xfco* -- the filter cutoff frequency in Hz. Should be in the range 0 to *sr*/2.

*xres* -- the amount of resonance. Self-oscillation occurs when *xres* is approximately 1. Should usually be in the range 0 to 1, however, values slightly greater than 1 are possible for more sustained oscillation and an “overdrive” effect.

*xdist* -- amount of distortion. *kdist* = 0 gives a clean output. *xdist* > 0 adds *tanh()* distortion controlled by the filter parameters, in such a way that both low cutoff and high resonance increase the distortion amount. Some experimentation is encouraged.

*lpf18* is a digital emulation of a 3 pole (18 dB/oct.) lowpass filter capable of self-oscillation with a built-in distortion unit. It is really a 3-pole version of *moogvcf*, retuned, recalibrated and with some performance improvements. The tuning and feedback tables use no more than 6 adds and 6 multiplies per control rate. The distortion unit, itself, is based on a modified *tanh* function driven by the filter controls.

### Note

Before version 6.04 this filter requires that the input signal be normalized to one.

## Examples

Here is an example of the lpf18 opcode. It uses the file *lpf18.csd* [examples/lpf18.csd].

### Example 451. Example of the lpf18 opcode.

# lpfreson

*lpfreson* — Resynthesises a signal from the data passed internally by a previous *lpread*, applying formant shifting.

## Description

Resynthesises a signal from the data passed internally by a previous *lpread*, applying formant shifting.

## Syntax

```
ares lpfreson asig, kfrqratio
```

## Performance

*asig* -- an audio driving function for resynthesis.

*kfrqratio* -- frequency ratio. Must be greater than 0.

*lpfreson* receives values internally produced by a leading *lpread*. *lpread* gets its values from the control file according to the input value *ktimpnt* (in seconds). If *ktimpnt* proceeds at the analysis rate, time-normal synthesis will result; proceeding at a faster, slower, or variable rate will result in time-warped synthesis. At each k-period, *lpread* interpolates between adjacent frames to more accurately determine the parameter values (presented as output) and the filter coefficient settings (passed internally to a subsequent *lpreson*).

The error signal *kerr* (between 0 and 1) derived during predictive analysis reflects the deterministic/random nature of the analyzed source. This will emerge low for pitched (periodic) material and higher for noisy material. The transition from voiced to unvoiced speech, for example, produces an error signal value of about .3. During synthesis, the error signal value can be used to determine the nature of the *lpreson* driving function: for example, by arbitrating between pitched and non-pitched input, or even by determining a mix of the two. In normal speech resynthesis, the pitched input to *lpreson* is a wideband periodic signal or pulse train derived from a unit such as *buzz*, and the nonpitched source is usually derived from *rand*. However, any audio signal can be used as the driving function, the only assumption of the analysis being that it has a flat response.

*lpfreson* is a formant shifted *lpreson*, in which *kfrqratio* is the (cps) ratio of shifted to original formant positions. This permits synthesis in which the source object changes its apparent acoustic size. *lpfreson* with *kfrqratio* = 1 is equivalent to *lpreson*.

Generally, *lpreson* provides a means whereby the time-varying content and spectral shaping of a composite audio signal can be controlled by the dynamic spectral content of another. There can be any number of *lpread/lpreson* (or *lpfreson*) pairs in an instrument or in an orchestra; they can read from the same or different control files independently.

## Examples

Here is an example of the *lpfreson* opcode. It uses the file *lpfreson.csd* [examples/lpfreson.csd].

### Example 452. Example of the *lpfreson* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# Iphasor

lphasor — Generates a table index for sample playback

## Description

This opcode can be used to generate table index for sample playback (e.g. `tablexkt`).

## Syntax

```
ares lphasor xtrns [, ilps] [, ilpe] [, imode] [, istrat] [, istor]
```

## Initialization

*ilps* -- loop start.

*ilpe* -- loop end (must be greater than *ilps* to enable looping). The default value of *ilps* and *ilpe* is zero.

*imode* (optional: default = 0) -- loop mode. Allowed values are:

- 0: no loop
- 1: forward loop
- 2: backward loop
- 3: forward-backward loop

*istrat* (optional: default = 0) -- The initial output value (phase). It must be less than *ilpe* if looping is enabled, but is allowed to be greater than *ilps* (i.e. you can start playback in the middle of the loop).

*istor* (optional: default = 0) -- skip initialization if set to any non-zero value.

## Performance

*ares* -- a raw table index in samples (same unit for loop points). Can be used as index with the table op-codes.

*xtrns* -- transpose factor, expressed as a playback ratio. *ares* is incremented by this value, and wraps around loop points. For example, 1.5 means a fifth above, 0.75 means fourth below. It is not allowed to be negative.

## Examples

Here is an example of the lphasor opcode. It uses the file *lphasor.csd* [examples/lphasor.csd].

### Example 453. Example of the Iphasor opcode.

# lpinterp

*lpslot*, *lpinterp* — Computes a new set of poles from the interpolation between two analysis.

## Description

Computes a new set of poles from the interpolation between two analysis.

## Syntax

```
lpinterp islot1, islot2, kmix
```

## Initialization

*islot1* -- slot where the first analysis was stored

*islot2* -- slot where the second analysis was stored

*kmix* -- mix value between the two analysis. Should be between 0 and 1. 0 means analysis 1 only. 1 means analysis 2 only. Any value in between will produce interpolation between the filters.

*lpinterp* computes a new set of poles from the interpolation between two analysis. The poles will be stored in the current *lpslot* and used by the next *lpreson* opcode.

## Examples

Here is a typical orc using the opcodes:

```
ipower init 50000 ; Define sound generator
ifreq init 440
asrc buzz ipower, ifreq, 10, 1

ktime line 0, p3, p3 ; Define time lin
lpslot 0 ; Read square data poles

# Iposcil

`lposcil` — Read sampled sound from a table with looping and high precision.

## Description

Read sampled sound (mono or stereo) from a table, with looping, and high precision.

## Syntax

```
ares lposcil kamp, kfreqratio, kloop, kend, ifn [, iphs]
```

## Initialization

*ifn* -- function table number

## Performance

*kamp* -- amplitude

*kfreqratio* -- multiply factor of table frequency (for example: 1 = original frequency, 1.5 = a fifth up , .5 = an octave down)

*kloop* -- start loop point (in samples)

*kend* -- end loop point (in samples)

*lposcil* (looping precise oscillator) allows varying at k-rate, the starting and ending point of a sample contained in a table (*GEN01*). This can be useful when reading a sampled loop of a wavetable, where repeat speed can be varied during the performance.

## Examples

Here is an example of the *lposcil* opcode. It uses the file *lposcil.csd* [examples/lposcil.csd].

### Example 454. Example of the *lposcil* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# lposcil3

`lposcil3` — Read sampled sound from a table with high precision and cubic interpolation.

## Description

Read sampled sound (mono or stereo) from a table, with looping, and high precision. *lposcil3* uses cubic interpolation.

## Syntax

```
ares lposcil3 kamp, kfreqratio, kloop, kend, ifn [, iphs]
```

## Initialization

*ifn* -- function table number

## Performance

*kamp* -- amplitude

*kfreqratio* -- multiply factor of table frequency (for example: 1 = original frequency, 1.5 = a fifth up, .5 = an octave down)

*kloop* -- start loop point (in samples)

*kend* -- end loop point (in samples)

*lposcil3* (looping precise oscillator) allows varying at k-rate, the starting and ending point of a sample contained in a table (*GEN01*). This can be useful when reading a sampled loop of a wavetable, where repeat speed can be varied during the performance.

## Examples

Here is an example of the *lposcil3* opcode. It uses the file *lposcil3.csd* [examples/lposcil3.csd].

# Iposcila

*lposcila* — Read sampled sound from a table with looping and high precision.

## Description

*lposcila* reads sampled sound from a table with looping and high precision.

## Syntax

```
ar lposcila aamp, kfreqratio, kloop, kend, ift [,iphhs]
```

## Initialization

*ift* -- function table number

*iphhs* -- initial phase (in samples)

## Performance

*ar* -- output signal

*aamp* -- amplitude

*kfreqratio* -- multiply factor of table frequency (for example: 1 = original frequency, 1.5 = a fifth up , .5 = an octave down)

*kloop* -- start loop point (in samples)

*kend* -- end loop point (in samples)

*lposcila* is the same as *lposcil*, but has an audio-rate amplitude argument (instead of k-rate) to allow fast envelope transients.

## Examples

Here is an example of the *lposcila* opcode. It uses the file *lposcila.csd* [examples/lposcila.csd].

### Example 456. Example of the *lposcila* opcode.

# lposcilsa

*lposcilsa* — Read stereo sampled sound from a table with looping and high precision.

## Description

*lposcilsa* reads stereo sampled sound from a table with looping and high precision.

## Syntax

```
ar1, ar2 lposcilsa aamp, kfrequratio, kloop, kend, ift [,iphhs]
```

## Initialization

*ift* -- function table number

*iphhs* -- initial phase (in samples)

## Performance

*ar1, ar2* -- output signal

*aamp* -- amplitude

*kfrequratio* -- multiply factor of table frequency (for example: 1 = original frequency, 1.5 = a fifth up , .5 = an octave down)

*kloop* -- start loop point (in samples)

*kend* -- end loop point (in samples)

*lposcilsa* is the same as *lposcila*, but works with stereo files loaded with *GEN01*.

## Examples

Here is an example of the *lposcilsa* opcode. It uses the file *lposcilsa.csd* [examples/lposcilsa.csd].

### Example 457. Example of the *lposcilsa* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>

# lposcilsa2

*lposcilsa2* — Read stereo sampled sound from a table with looping and high precision.

## Description

*lposcilsa2* reads stereo sampled sound from a table with looping and high precision.

## Syntax

```
ar1, ar2 lposcilsa2 aamp, kfreqratio, kloop, kend, ift [,iphhs]
```

## Initialization

*ift* -- function table number

*iphhs* -- initial phase (in samples)

## Performance

*ar1, ar2* -- output signal

*aamp* -- amplitude

*kfreqratio* -- multiply factor of table frequency (for example: 1 = original frequency, 2 = an octave up). Only integers are allowed

*kloop* -- start loop point (in samples)

*kend* -- end loop point (in samples)

*lposcilsa2* is the same as *lposcilsa*, but no interpolation is implemented and only works with integer *kfreqratio* values. Much faster than *lposcilsa*, it is mainly intended to be used with *kfreqratio* = 1, being in this case a fast substitute of *soundin*, since the soundfile must be entirely loaded in memory.

## Examples

Here is an example of the *lposcilsa2* opcode. It uses the file *lposcilsa2.csd* [examples/lposcilsa2.csd].

# lpread

*lpread* — Reads a control file of time-ordered information frames.

## Description

Reads a control file of time-ordered information frames.

## Syntax

```
krmsr, krms0, kerr, kcps lpread ktimpnt, ifilcod [, inpoles] [, ifrmrate]
```

## Initialization

*ifilcod* -- integer or character-string denoting a control-file (reflection coefficients and four parameter values) derived from n-pole linear predictive spectral analysis of a source audio signal. An integer denotes the suffix of a file *lp.m*; a character-string (in double quotes) gives a filename, optionally a full pathname. If not fullpath, the file is sought first in the current directory, then in that of the environment variable SADIR (if defined). Memory usage depends on the size of the file, which is held entirely in memory during computation but shared by multiple calls (see also *adsyn*, *pvc*).

*inpoles* (optional, default=0) -- number of poles in the lpc analysis. It is required only when the control file does not have a header; it is ignored when a header is detected.

*ifrmrate* (optional, default=0) -- frame rate per second in the lpc analysis. It is required only when the control file does not have a header; it is ignored when a header is detected.

## Performance

*lpread* accesses a control file of time-ordered information frames, each containing n-pole filter coefficients derived from linear predictive analysis of a source signal at fixed time intervals (e.g. 1/100 of a second), plus four parameter values:

*krmsr* -- root-mean-square (rms) of the residual of analysis

*krms0* -- rms of the original signal

*kerr* -- the normalized error signal

*kcps* -- pitch in Hz

*ktimpnt* -- The passage of time, in seconds, through the analysis file. *ktimpnt* must always be positive, but can move forwards or backwards in time, be stationary or discontinuous, as a pointer into the analysis file.

*lpread* gets its values from the control file according to the input value *ktimpnt* (in seconds). If *ktimpnt* proceeds at the analysis rate, time-normal synthesis will result; proceeding at a faster, slower, or variable rate will result in time-warped synthesis. At each k-period, *lpread* interpolates between adjacent frames to more accurately determine the parameter values (presented as output) and the filter coefficient settings (passed internally to a subsequent *lpreson*).

The error signal *kerr* (between 0 and 1) derived during predictive analysis reflects the deterministic/random nature of the analyzed source. This will emerge low for pitched (periodic) material and higher for

noisy material. The transition from voiced to unvoiced speech, for example, produces an error signal value of about .3. During synthesis, the error signal value can be used to determine the nature of the *lpreson* driving function: for example, by arbitrating between pitched and non-pitched input, or even by determining a mix of the two. In normal speech resynthesis, the pitched input to *lpreson* is a wideband periodic signal or pulse train derived from a unit such as *buzz*, and the nonpitched source is usually derived from *rand*. However, any audio signal can be used as the driving function, the only assumption of the analysis being that it has a flat response.

*lpfreson* is a formant shifted *lpreson*, in which *kfrqratio* is the (cps) ratio of shifted to original formant positions. This permits synthesis in which the source object changes its apparent acoustic size. *lpfreson* with *kfrqratio* = 1 is equivalent to *lpreson*.

Generally, *lpreson* provides a means whereby the time-varying content and spectral shaping of a composite audio signal can be controlled by the dynamic spectral content of another. There can be any number of lpread/lpreson (or lpfreson) pairs in an instrument or in an orchestra; they can read from the same or different control files independently.

## Examples

Here is an example of the lpread opcode. It uses the file *lpread.csd* [examples/lpread.csd].

# lpreson

*lpreson* — Resynthesises a signal from the data passed internally by a previous *lpread*.

## Description

Resynthesises a signal from the data passed internally by a previous *lpread*.

## Syntax

```
ares lpreson asig
```

## Performance

*asig* -- an audio driving function for resynthesis.

*lpreson* receives values internally produced by a leading *lpread*. *lpread* gets its values from the control file according to the input value *ktimpnt* (in seconds). If *ktimpnt* proceeds at the analysis rate, time-normal synthesis will result; proceeding at a faster, slower, or variable rate will result in time-warped synthesis. At each k-period, *lpread* interpolates between adjacent frames to more accurately determine the parameter values (presented as output) and the filter coefficient settings (passed internally to a subsequent *lpreson*).

The error signal *kerr* (between 0 and 1) derived during predictive analysis reflects the deterministic/random nature of the analyzed source. This will emerge low for pitched (periodic) material and higher for noisy material. The transition from voiced to unvoiced speech, for example, produces an error signal value of about .3. During synthesis, the error signal value can be used to determine the nature of the *lpreson* driving function: for example, by arbitrating between pitched and non-pitched input, or even by determining a mix of the two. In normal speech resynthesis, the pitched input to *lpreson* is a wideband periodic signal or pulse train derived from a unit such as *buzz*, and the nonpitched source is usually derived from *rand*. However, any audio signal can be used as the driving function, the only assumption of the analysis being that it has a flat response.

*lpfreson* is a formant shifted *lpreson*, in which *kfrqratio* is the (cps) ratio of shifted to original formant positions. This permits synthesis in which the source object changes its apparent acoustic size. *lpfreson* with *kfrqratio* = 1 is equivalent to *lpreson*.

Generally, *lpreson* provides a means whereby the time-varying content and spectral shaping of a composite audio signal can be controlled by the dynamic spectral content of another. There can be any number of *lpread/lpreson* (or *lpfreson*) pairs in an instrument or in an orchestra; they can read from the same or different control files independently.

# Ipshold

lpshold — Generate control signal consisting of held segments.

## Description

Generate control signal consisting of held segments delimited by two or more specified points. The entire envelope is looped at *kfreq* rate. Each parameter can be varied at k-rate.

## Syntax

```
ksig lpshold kfreq, ktrig, iphase, ktime0, kvalue0 [, kvalue1] [, ktime1] [, kvalue2] [, ktime2] [...]
```

## Performance

*ksig* -- Output signal

*kfreq* -- Repeat rate in Hz or fraction of Hz

*ktrig* -- If non-zero, retriggers the envelope from start (see *trigger opcode*), before the envelope cycle is completed.

*iphase* -- A value between 0 and 1 to say where to start the loop. Zero, the commonest value, indicates the beginning.

*kvalue0...kvalueN* -- Values of points

*ktime0...ktimeN* -- Times between points; expressed in fractions of a cycle (see below). The final time designates a ramp between the final value and the first value.

*lpshold* is similar to *loopseg*, but can generate only horizontal segments, i.e. holds values for each time interval placed between *ktimeN* and *ktimeN+1*. It can be useful, among other things, for melodic control, like old analog sequencers.

## Examples

Here is an example of the lpshold opcode. It uses the file *lpshold.csd* [examples/lpshold.csd].

# lpsholdp

lpsholdp — Control signals based on held segments.

## Description

Generate control signal consisting of held segments delimited by two or more specified points. The entire envelope can be looped at time-variant rate. Each segment coordinate can also be varied at k-rate.

## Syntax

```
ksig lpsholdp kphase, kvalue0, ktime0 [, kvalue1] [, ktime1] \
[, kvalue2] [, ktime2] [...]
```

## Performance

*ksig* - output signal

*kphase* -- point of the sequence read, expressed as a fraction of a cycle (0 to 1)

*kvalue0*...*kvalueN* -- Values of points

*ktime0*...*ktimeN* -- Times between points; expressed in fractions of a cycle (see below). The final time designates a ramp between the final value and the first value.

*lpsholdp* opcode is similar to *lpshold*; the only difference is that, instead of frequency, a time-variant phase is required. If you use a phasor to get the phase value, you will have a behaviour identical to *lpshold*, but interesting results can be achieved when using phases having non-linear motions, making *lpsholdp* more powerful and general than *lpshold*.

# Ipslot

`lpslot` — Selects the slot to be used by further lp opcodes.

## Description

Selects the slot to be used by further lp opcodes.

## Syntax

```
lpslot islot
```

## Initialization

*islot* -- number of slot to be selected.

## Performance

`lpslot` selects the slot to be used by further lp opcodes. This is the way to load and reference several analyses at the same time.

## Examples

Here is a typical orc using the opcodes:

```
ipower init 50000 ; Define sound generator
ifreq init 440
asrc buzz ipower, ifreq, 10, 1

ktime line 0, p3, p3 ; Define time lin
lpslot 0 ; Read square data poles
krmsr, krmso, kerr, kcps lpread ktime,"square.pol"
lpslot 1 ; Read triangle data poles
krmsr, krmso, kerr, kcps lpread ktime,"triangle.pol"
kmix line 0, p3, 1 ; Compute result of mixing
lpinterp 0, 1, kmix ; and balance power
ares lpreson asrc
aout balance ares, asrc
out aout
```

# lua\_exec

`lua_exec` — Executes an arbitrary block of Lua code from the Csound orchestra.

## Note

plugin: Requires lua plugin

## Description

Executes an arbitrary block of Lua code from the Csound orchestra. The code is executed at initialization time, typically from the orchestra header.

## Syntax

```
lua_exec Sluacode
```

## Initialization

*Sluacode* -- A block of Lua code, of any length. Multi-line blocks may be enclosed in double braces (i.e. `{ { } }`). This code is evaluated once at initialization time, typically from the orchestra header. Global and local variables, functions, tables, and classes may be declared and defined. Objects defined at global Lua scope remain in scope throughout the performance, and are visible to any other Lua code in the same Csound thread.

The running instance of Csound is stored as a Lua lightuserdata in a global variable `csound`. This can be passed to any Csound API function. One use of this would be to generate a score using Lua in the orchestra header, and schedule the events for performance using `csoundInputMessage`.

## Note

By default, all objects defined in Lua are defined at global scope. In order to ensure that objects are confined to their own block of code, that is to ensure that the object is visible only in lexical scope, the object must be declared as local. This is the feature of Lua that beginners tend to find the most troublesome.

Another thing to look out for is that Lua arrays use 1-based indexing, not the 0-based indexing used in C and many other programming languages.

## lua\_opdef

`lua_opdef` — Define an opcode in Lua at i-rate. The opcode can take any number of output and/or input arguments of any type.

## Description

Define an opcode in Lua at i-rate. The opcode can take any number of output and/or input arguments of any type. The code is executed at initialization time, typically from the orchestra header. Global and local variables, functions, tables, and classes may be declared and defined. Objects defined at global Lua scope remain in scope throughout the performance, and are visible to any other Lua code in the same Csound thread.

### Note

By default, all objects defined in Lua are defined at global scope. In order to ensure that objects are confined to their own block of code, that is to ensure that the object is visible only in lexical scope, the object must be declared as local. This is the feature of Lua that beginners tend to find the most troublesome.

Another thing to look out for is that Lua arrays use 1-based indexing, not the 0-based indexing used in C and many other programming languages.

## Syntax

```
lua_opdef Sname, Sluacode
```

## Initialization

*Sname* -- The name of the opcode.

*Sluacode* -- A block of Lua code, of any length. Multi-line blocks may be enclosed in double braces (i.e. `{ { } }`). This code is evaluated once at initialization time.

The Lua code must define all functions that will be called from Csound, using the following naming convention, where `opcodename` stands for the actual opcode name:

- `opcodename_init` for the i-rate opcode subroutine.
- `opcodename_kontrol` for the k-rate opcode subroutine.
- `opcodename_audio` for the a-rate opcode subroutine.
- `opcodename_noteoff` for the note-off subroutine.

Each of these Lua functions will receive three lightuserdata (i.e. pointer) arguments: the CSOUND object, the opcode instance, and a pointer to the opcode arguments, which the Lua code must be type cast to a LuaJIT FFI ctype structure containing the opcode output arguments, input arguments, and state variables. Using LuaJIT FFI, the elements of this structure will be accessible as though they were Lua types.

Each of these Lua functions must return 0 for success or 1 for failure.

The Lua functions may do absolutely anything, although of course if real-time performance is expected, care must be taken to disable Lua garbage collection and observe other recommendations for real-time code.

## Example

Here is an example of a Lua opcode, implementing a Moog ladder filter. For purposes of comparison, a user-defined opcode and the native Csound opcode that compute the same sound using the same algorithm also are shown, and timed. The example uses the file *luamoog.csd* [examples/luamoog.csd].

### Example 463. Example of a Lua opcode.

## lua\_opcall

`lua_opcall` — Calls a Lua opcode at i-rate only. Any number of output and/or input arguments may be passed. All arguments must be passed on the right-hand side. Outputs are returned in the argument.

### Syntax

```
lua_iopcall Sname, ...  
  
lua_ikopcall Sname, ...  
  
lua_iaopcall Sname, ...  
  
lua_iopcall_off Sname, ...  
  
lua_ikopcall_off Sname, ...  
  
lua_iaopcall_off Sname, ...
```

## Initialization and Performance

*Sname* -- The name of the opcode.

... -- An arbitrary list of any number of output and input arguments, of any type. The number, sequence, and types of these arguments must agree with the cdef of the arguments structure that is declared in the corresponding `lua_opdef` opcode.

`lua_iopcall` calls a Lua opcode at i-rate only. Requires `opname_init` to be defined in Lua.

`lua_ikopcall` calls a Lua opcode at i-rate and k-rate. Requires `opname_init` and `opname_kontrol` to be defined in Lua.

`lua_iaopcall` calls a Lua opcode at i-rate and a-rate. Requires `opname_init` and `opname_audio` to be defined in Lua.

`lua_iopcall_off` calls a Lua opcode at i-rate only. Requires `opname_init` and `opname_noteoff` to be defined in Lua.

`lua_ikopcall_off` calls a Lua opcode at i-rate and k-rate. Requires `opname_init`, `opname_kontrol`, and `opname_noteoff` to be defined in Lua.

`lua_iaopcall_off` calls a Lua opcode at i-rate and a-rate. Requires `opname_init`, `opname_audio`, and `opname_noteoff` to be defined in Lua.

Lua code accesses elements of arguments as follows (pointers to both scalars and arrays are dereferenced by the Lua array access operator):

```
ffi.cdef(' struct arguments_t { double *a_out, double *i_in, double *i_txt, double *f_sig }  
local arguments = ffi.cast("struct arguments_t *", carguments_lightuserdata)  
for i = 0, ksmpls -1 do begin carguments.a_out[i] = carguments.i_in[0] * 3 end end')
```

The "off" variants of the opcode always schedule a "note off" event that is called when the instrument instance is removed from the active list, and which can be used to release unneeded resources, reschedule the instrument to render a reverb tail, and so on.

## Example

Here is an example of a Lua opcode, showing how to pass strings back and forth between Lua opcodes and Csound orchestra code. The example uses the file *luaopcode.csd* [examples/luaopcode.csd].

### Example 464. Example of a Lua opcode.

```
<CsoundSynthesizer>
<CsInstruments>
lua_opdef "luatest", {
local ffi = require("ffi")
local string = require("string")
local csoundLibrary = ffi.load('csound64.dll.5.2')
ffi.cdef[[
    int csoundGetKsmpls(void *);
    double csoundGetSr(void *);
    struct luatest_arguments {double *out; double *stringout; char *stringin; double *in1; double *in2,
    }];
function luatest_init(csound, opcode, carguments)
    local arguments = ffi.cast("struct luatest_arguments *", carguments)
    arguments.sr = csoundLibrary.csoundGetSr(csound)
    print(string.format('stringin: %s', ffi.string(arguments.stringin)))
    print(string.format('sr: %f', arguments.sr))
    arguments.ksmps = csoundLibrary.csoundGetKsmpls(csound)
    print(string.format('ksmps: %d', arguments.ksmps))
    arguments.out[0] = arguments.in1[0] * arguments.in2[0]
    ffi.copy(arguments.stringout, 'Hello, world!')
    return 0
end
function luatest_kontrol(csound, opcode, carguments)
    local arguments = ffi.cast("struct luatest_arguments *", carguments)
    arguments.out[0] = arguments.in1[0] * arguments.in2[0]
    return 0
end
function luatest_noteoff(csound, opcode, carguments)
    local arguments = ffi.cast("struct luatest_arguments *", carguments)
    arguments.out[0] = arguments.in1[0] * arguments.in2[0]
    print('off')
    return 0
end
}
instr 1
iresult = 0
Stringin = "stringin"
Stringout = "stringout"
lua_iopcall "luatest", iresult, Stringout, Stringin, p2, p3
prints Stringout
endin

# mac

mac — Multiplies and accumulates a- and k-rate signals.

## Description

Multiplies and accumulates a- and k-rate signals.

## Syntax

```
ares mac ksig1, asig1 [, ksig2] [, asig2] [, ksig3] [, asig3] [...]
```

## Performance

*ksig1*, etc. -- k-rate input signals

*asig1*, etc. -- a-rate input signals

*mac* multiplies and accumulates a- and k-rate signals. It is equivalent to:

```
ares = asig1*ksig1 + asig2*ksig2 + asig3*ksig3 + ...
```

## Examples

Here is an example of the mac opcode. It uses the file *mac.csd* [examples/mac.csd]. It is written for \*NIX systems, and will generate errors on Windows.

### Example 465. Example of the mac opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# maca

maca — Multiply and accumulate a-rate signals only.

## Description

Multiply and accumulate a-rate signals only.

## Syntax

```
ares maca asig1 , asig2 [, asig3] [, asig4] [, asig5] [...]
```

## Performance

*asig1, asig2, ...* -- a-rate input signals

*maca* multiplies and accumulates a-rate signals only. It is equivalent to:

```
ares = asig1*asig2 + asig3*asig4 + asig5*asig6 + ...
```

## Examples

Here is an example of the maca opcode. It uses the file *maca.csd* [examples/maca.csd]. It is written for \*NIX systems, and will generate errors on Windows.

### Example 466. Example of the maca opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# madsr

madsr — Calculates the classical ADSR envelope using the *linsegr* mechanism.

## Description

Calculates the classical ADSR envelope using the *linsegr* mechanism.

## Syntax

```
ares madsr iatt, idec, islev, irel [, idel] [, ireltim]
```

```
kres madsr iatt, idec, islev, irel [, idel] [, ireltim]
```

## Initialization

*iatt* -- duration of attack phase

*idec* -- duration of decay

*islev* -- level for sustain phase

*irel* -- duration of release phase.

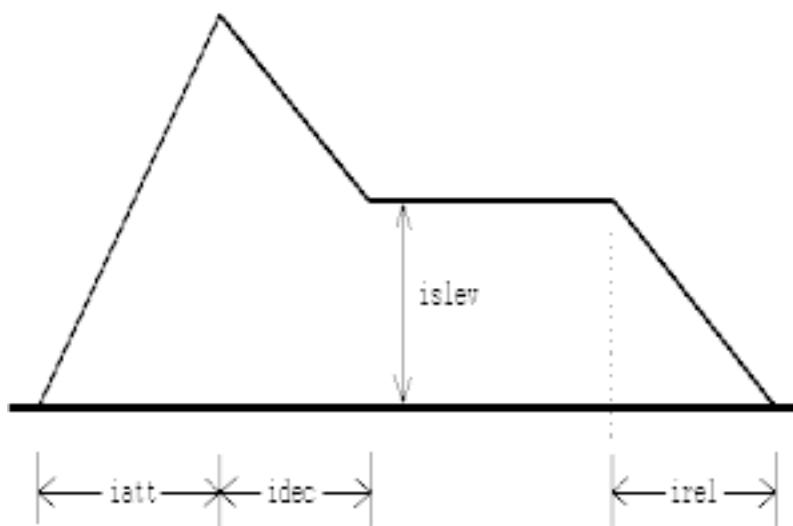

*idel* -- period of zero before the envelope starts

*ireltim* (optional, default=-1) -- Control release time after receiving a MIDI noteoff event. If less than zero, the longest release time given in the current instrument is used. If zero or more, the given value will be used for release time. Its default value is -1. (New in Csound 3.59 - not yet properly tested)

Please note that the release time cannot be longer than  $32767/kr$  seconds.

## Performance

The envelope is in the range 0 to 1 and may need to be scaled further. The envelope may be described as:

Picture of an ADSR envelope.

The length of the sustain is calculated from the length of the note. This means *adsr* is not suitable for use with MIDI events. The opcode *madsr* uses the *linsegr* mechanism, and so can be used in MIDI applications.

You can use other pre-made envelopes which start a release segment upon receiving a note off message, like *linsegr* and *expsegr*, or you can construct more complex envelopes using *xratim* and *release*. Note that you don't need to use *xratim* if you are using *madsr*, since the time is extended automatically.

### Note

Times for *iatt*, *idec* and *irel* cannot be 0. If 0 is used, no envelope is generated. Use a very small value like 0.0001 if you need an instantaneous attack, decay or release.

## Examples

Here is an example of the *madsr* opcode. It uses the file *madsr.csd* [examples/madsr.csd].

### Example 467. Example of the madsr opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# mags

mags — Obtains the magnitudes of a complex-number array

## Description

This opcode returns the magnitudes of a complex-number array (in rfft format), as a real-valued array with half the size of its input plus one. The magnitude for the Nyquist frequency are kept in the last position of the array.

## Syntax

```
kout[] mags kin[]
```

## Performance

*kout[]* -- output array containing the magnitudes (size = *input\_size*/2 + 1). It will be created if it does not exist.

*kin[]* -- input array containing the complex-valued real-imaginary input.

## Examples

Here is an example of the mags opcode. It uses the file *mags.csd* [examples/mags.csd].

### Example 469. Example of the mags opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# mandel

mandel — Mandelbrot set

## Description

Returns the number of iterations corresponding to a given point of complex plane by applying the Mandelbrot set formula.

## Syntax

```
kiter, koutrig mandel ktrig, kx, ky, kmaxIter
```

## Performance

*kiter* - number of iterations

*koutrig* - output trigger signal

*ktrig* - input trigger signal

*kx*, *ky* - coordinates of a given point belonging to the complex plane

*kmaxIter* - maximum iterations allowed

*mandel* is an opcode that allows the use of the Mandelbrot set formula to generate an output that can be applied to any musical (or non-musical) parameter. It has two output arguments: *kiter*, that contains the iteration number of a given point, and *koutrig*, that generates a trigger 'bang' each time *kiter* changes. A new number of iterations is evaluated only when *ktrig* is set to a non-zero value. The coordinates of the complex plane are set in *kx* and *ky*, while *kmaxIter* contains the maximum number of iterations. Output values, which are integer numbers, can be mapped in any sorts of ways by the composer.

## Examples

Here is an example of the *mandel* opcode. It uses the file *mandel.csd* [examples/mandel.csd].

### Example 470. Example of the *mandel* opcode.

# mandol

mandol — An emulation of a mandolin.

## Description

An emulation of a mandolin.

## Syntax

```
ares mandol kamp, kfreq, kpluck, kdetune, kgain, ksize \
[, ifn] [, iminfreq]
```

## Initialization

*ifn* -- table number containing the pluck wave form. The file *mandpluk.aiff* [examples/mandpluk.aiff] is suitable for this. It is also available at <ftp://ftp.cs.bath.ac.uk/pub/dream/documentation/sounds/modelling/>.

*iminfreq* (optional, default=0) -- Lowest frequency to be played on the note. If it is omitted it is taken to be the same as the initial *kfreq*.

## Performance

*kamp* -- Amplitude of note.

*kfreq* -- Frequency of note played.

*kpluck* -- The pluck position, in range 0 to 1. Suggest 0.4.

*kdetune* -- The proportional detuning between the two strings. Suggested range 0.9 to 1.

*kgain* -- the loop gain of the model, in the range 0.97 to 1.

*ksize* -- The size of the body of the mandolin. Range 0 to 2.

## Examples

Here is an example of the mandol opcode. It uses the file *mandol.csd* [examples/mandol.csd], and *mandpluk.aiff* [examples/mandpluk.aiff].

### Example 471. Example of the mandol opcode.

# maparray

maparray — Apply a function to every element of a vector.

## Description

Apply a function of one argument to every element of a vector (one-dimensional k-rate array).

## Syntax

```
karray maparray kinarray, String  
  
karray maparray_i kinarray, String
```

## Initialization

*String* -- a string that names an opcode function, at i-rate for maparray\_i or k-rate for maparray.

## Performance

*karray* -- array for answers.

*kinarray* -- array for arguments to the function.

## Examples

Here is an example of the maparray opcode. It uses the file *maparray.csd* [examples/maparray.csd].

### Example 472. Example of the maparray opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# marimba

marimba — Physical model related to the striking of a wooden block.

## Description

Audio output is a tone related to the striking of a wooden block as found in a marimba. The method is a physical model developed from Perry Cook but re-coded for Csound.

## Syntax

```
ares marimba kamp, kfreq, ihrd, ipos, imp, kvibf, kvamp, ivibfn, idec \
[, idoubles] [, itriples]
```

## Initialization

*ihrd* -- the hardness of the stick used in the strike. A range of 0 to 1 is used. 0.5 is a suitable value.

*ipos* -- where the block is hit, in the range 0 to 1.

*imp* -- a table of the strike impulses. The file *marmstk1.wav* [examples/marmstk1.wav] is a suitable function from measurements and can be loaded with a *GEN01* table. It is also available at <ftp://ftp.cs.bath.ac.uk/pub/dream/documentation/sounds/modelling/>.

*ivfn* -- shape of vibrato, usually a sine table, created by a function

*idec* -- time before end of note when damping is introduced

*idoubles* (optional) -- percentage of double strikes. Default is 40%.

*itriples* (optional) -- percentage of triple strikes. Default is 20%.

## Performance

*kamp* -- Amplitude of note.

*kfreq* -- Frequency of note played.

*kvibf* -- frequency of vibrato in Hertz. Suggested range is 0 to 12

*kvamp* -- amplitude of the vibrato

## Examples

Here is an example of the marimba opcode. It uses the file *marimba.csd* [examples/marimba.csd], and *marmstk1.wav* [examples/marmstk1.wav].

### Example 473. Example of the marimba opcode.

# massign

`massign` — Assigns a MIDI channel number to a Csound instrument.

## Description

Assigns a MIDI channel number to a Csound instrument.

## Syntax

```
massign ichnl, insnum[, ireset]  
  
massign ichnl, "insname"[, ireset]
```

## Initialization

*ichnl* -- MIDI channel number (1-16).

*insnum* -- Csound orchestra instrument number. If zero or negative, the channel is muted (i.e. it doesn't trigger a csound instrument, though information will still be received by opcodes like *midiin*).

“*insname*” -- A string (in double-quotes) representing a named instrument.

*ireset* -- If non-zero resets the controllers; default is to reset.

## Performance

Assigns a MIDI channel number to a Csound instrument. Also useful to make sure a certain instrument (if its number is from 1 to 16) will not be triggered by midi noteon messages (if using something *midiin* to interpret midi information). In this case set *insnum* to 0 or a negative number.

If *ichan* is set to 0, the value of *insnum* is used for all channels. This way you can route all MIDI channels to a single Csound instrument. You can also disable triggering of instruments from MIDI note events from all channels with the following line:

```
massign 0,0
```

This can be useful if you are doing all MIDI evaluation within Csound with an always on instrument(e.g. using *midiin* and *turnon*) to avoid doubling the instrument when a note is played.

## Examples

Here is an example of the massign opcode. It uses the file *massign.csd* [examples/massign.csd].

### Example 474. Example of the massign opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# max

**max** — Produces a signal that is the maximum of any number of input signals.

## Description

The **max** opcode takes any number of a-rate, k-rate or i-rate signals as input (all of the same rate), and outputs a signal at the same rate that is the maximum of all of the inputs. For a-rate signals, the inputs are compared one sample at a time (i.e. **max** does not scan an entire ksmmps period of a signal for its local maximum as the **max\_k** opcode does).

## Syntax

```
aamax max ain1, ain2 [, ain3] [, ain4] [...]  
  
kmax max kin1, kin2 [, kin3] [, kin4] [...]  
  
imax max iin1, iin2 [, iin3] [, iin4] [...]
```

## Performance

*ain1, ain2, ...* -- a-rate signals to be compared.

*kin1, kin2, ...* -- k-rate signals to be compared.

*iin1, iin2, ...* -- i-rate signals to be compared.

## Examples

Here is an example of the max opcode. It uses the file *max.csd* [examples/max.csd].

# maxabs

maxabs — Produces a signal that is the maximum of the absolute values of any number of input signals.

## Description

The *maxabs* opcode takes any number of a-rate or k-rate signals as input (all of the same rate), and outputs a signal at the same rate that is the maximum of all of the inputs. It is identical to the *max* opcode except that it takes the absolute value of each input before comparing them. Therefore, the output is always non-negative. For a-rate signals, the inputs are compared one sample at a time (i.e. *maxabs* does not scan an entire ksmps period of a signal for its local maximum as the *max\_k* opcode does).

## Syntax

```
amax maxabs ain1, ain2 [, ain3] [, ain4] [...]  
  
kmax maxabs kin1, kin2 [, kin3] [, kin4] [...]
```

## Performance

*ain1, ain2, ...* -- a-rate signals to be compared.

*kin1, kin2, ...* -- k-rate signals to be compared.

## Examples

Here is an example of the maxabs opcode. It uses the file *maxabs.csd* [examples/maxabs.csd].

### Example 476. Example of the maxabs opcode.

# maxabsaccum

`maxabsaccum` — Accumulates the maximum of the absolute values of audio signals.

## Description

*maxabsaccum* compares two audio-rate variables and stores the maximum of their absolute values into the first.

## Syntax

```
maxabsaccum aAccumulator, aInput
```

## Performance

*aAccumulator* -- audio variable to store the maximum value

*aInput* -- signal that *aAccumulator* is compared to

The *maxabsaccum* opcode is designed to accumulate the maximum value from among many audio signals that may be in different note instances, different channels, or otherwise cannot all be compared at once using the *maxabs* opcode. *maxabsaccum* is identical to *maxaccum* except that it takes the absolute value of *aInput* before the comparison. Its semantics are similar to *vincr* since *aAccumulator* is used as both an input and an output variable, except that *maxabsaccum* keeps the maximum absolute value instead of adding the signals together. *maxabsaccum* performs the following operation on each pair of samples:

```
if (abs(aInput) > aAccumulator) aAccumulator = abs(aInput)
```

*aAccumulator* will usually be a global audio variable. At the end of any given computation cycle (k-period), after its value is read and used in some way, the accumulator variable should usually be reset to zero (perhaps by using the *clear* opcode). Clearing to zero is sufficient for *maxabsaccum*, unlike the *maxaccum* opcode.

## Examples

Here is an example of the *maxabsaccum* opcode. It uses the file *maxabsaccum.csd* [examples/maxabsaccum.csd].

### Example 477. Example of the maxabsaccum opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# maxaccum

`maxaccum` — Accumulates the maximum value of audio signals.

## Description

`maxaccum` compares two audio-rate variables and stores the maximum value between them into the first.

## Syntax

```
maxaccum aAccumulator, aInput
```

## Performance

*aAccumulator* -- audio variable to store the maximum value

*aInput* -- signal that *aAccumulator* is compared to

The `maxaccum` opcode is designed to accumulate the maximum value from among many audio signals that may be in different note instances, different channels, or otherwise cannot all be compared at once using the `max` opcode. Its semantics are similar to `vincr` since *aAccumulator* is used as both an input and an output variable, except that `maxaccum` keeps the maximum value instead of adding the signals together. `maxaccum` performs the following operation on each pair of samples:

```
if (aInput > aAccumulator) aAccumulator = aInput
```

*aAccumulator* will usually be a global audio variable. At the end of any given computation cycle (k-period), after its value is read and used in some way, the accumulator variable should usually be reset to zero (perhaps by using the `clear` opcode). Care must be taken however if *aInput* is negative at any point, in which case the accumulator should be initialized and reset to some large enough negative value that will always be less than the input signals to which it is compared.

## Examples

Here is an example of the `maxaccum` opcode. It uses the file `maxaccum.csd` [examples/maxaccum.csd].

### Example 478. Example of the maxabs opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# maxalloc

`maxalloc` — Limits the number of allocations of an instrument.

## Description

Limits the number of allocations of an instrument.

## Syntax

```
maxalloc insnum, ictcount  
  
maxalloc Sinsname, ictcount
```

## Initialization

*insnum* -- instrument number

*Sinsname* -- instrument name

*ictcount* -- number of instrument allocations

## Performance

`maxalloc` limits the number of simultaneous instances (notes) of an instrument. Any score events after the maximum has been reached, are ignored.

All instances of `maxalloc` must be defined in the header section, not in the instrument body.

## Examples

Here is an example of the `maxalloc` opcode. It uses the file `maxalloc.csd` [examples/maxalloc.csd].

### Example 479. Example of the maxalloc opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>  
<CsOptions>

# max\_k

max\_k — Local maximum (or minimum) value of an incoming asig signal

## Description

*max\_k* outputs the local maximum (or minimum) value of the incoming asig signal, checked in the time interval between *ktrig* has become true twice.

## Syntax

```
knumkout max_k asig, ktrig, itype
```

## Initialization

*itype* - *itype* determinates the behaviour of max\_k (see below)

## Performance

*asig* - incoming (input) signal

*ktrig* - trigger signal

max\_k outputs the local maximum (or minimum) value of the incoming *asig* signal, checked in the time interval between *ktrig* has become true twice. *itype* determinates the behaviour of max\_k:

- 1 - absolute maximum (sign of negative values is changed to positive before evaluation).
- 2 - actual maximum.
- 3 - actual minimum.
- 4 - calculate average value of *asig* in the time interval since the last trigger.

This opcode can be useful in several situations, for example to implement a vu-meter.

## Examples

Here is an example of the max\_k opcode. It uses the file *max\_k.csd* [examples/max\_k.csd].

### Example 480. Example of the max\_k opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# maxarray

maxarray — returns the maximum value in an array.

## Description

The *maxarray* opcode returns the maximum value in a k-rate array, and optional its index.

## Syntax

```
kmax [,kindx] maxarray karray
```

## Performance

*kmax* -- variable for result.

*kindx* -- position (index) of result in array.

*karray* -- array for reading.

## Examples

Here is an example of the maxarray opcode. It uses the file *maxarray.csd* [examples/maxarray.csd].

### Example 481. Example of the maxarray opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# mclock

mclock — Sends a MIDI CLOCK message.

## Description

Sends a MIDI CLOCK message.

## Syntax

```
mclock ifreq
```

## Initialization

*ifreq* -- clock message frequency rate in Hz

## Performance

Sends a MIDI CLOCK message (0xF8) every  $1/ifreq$  seconds. So *ifreq* is the frequency rate of CLOCK message in Hz.

## See Also

*mrtmsg*

## Examples

Here is an example of the mclock opcode. It uses the file *mclock.csd* [examples/mclock.csd].

### Example 482. Example of the mclock opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# mdelay

mdelay — A MIDI delay opcode.

## Description

A MIDI delay opcode.

## Syntax

```
mdelay kstatus, kchan, kd1, kd2, kdelay
```

## Performance

*kstatus* -- status byte of MIDI message to be delayed

*kchan* -- MIDI channel (1-16)

*kd1* -- first MIDI data byte

*kd2* -- second MIDI data byte

*kdelay* -- delay time in seconds

Each time that *kstatus* is other than zero, *mdelay* outputs a MIDI message to the MIDI out port after *kdelay* seconds. This opcode is useful in implementing MIDI delays. Several instances of *mdelay* can be present in the same instrument with different argument values, so complex and colorful MIDI echoes can be implemented. Further, the delay time can be changed at k-rate.

## Examples

Here is an example of the *mdelay* opcode. It uses the file *mdelay.csd* [examples/mdelay.csd].

### Example 483. Example of the mdelay opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# median

median — A median filter, a variant FIR lowpass filter.

## Description

Implementation of a median filter.

## Syntax

```
ares median asig, ksize, imaxsize [, iskip]
```

## Initialization

*imaxsize* -- the maximum size of the window used to select the data.

*iskip* -- initial disposition of internal data space. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*asig* -- input signal to be filtered

*ksize* -- size of the window over which the input is to be filtered. It must not exceed the maximum window size; if it does it is truncated.

*median* is a simple filter that returns the median value of the last *ksize* values. It has a lowpass action. The efficiency decreases as the window size increases.

## Examples

Here is an example of the median opcode. It uses the file *median.csd* [examples/median.csd].

### Example 484. Example of the median opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# mediank

mediank — A median filter, a variant FIR lowpass filter.

## Description

Implementation of a median filter.

## Syntax

```
kres mediank kin, ksize, imaxsize [, iskip]
```

## Initialization

*imaxsize* -- the maximum size of the window used to select the data.

*iskip* -- initial disposition of internal data space. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*kin* -- krate value to be filtered

*ksize* -- size of the window over which the input is to be filtered. It must not exceed the maximum window size; if it does it is truncated.

*mediank* is a simple filter that returns the median value of the last *ksize* values. It has a lowpass action. The efficiency decreases as the window size increases.

## Examples

Here is an example of the mediank opcode. It uses the file *mediank.csd* [examples/mediank.csd].

### Example 485. Example of the mediank opcode.

# metro

metro — Trigger Metronome

## Description

Generate a metronomic signal to be used in any circumstance an isochronous trigger is needed.

## Syntax

```
ktrig metro kfreq [, initphase]
```

## Initialization

*initphase* - initial phase value (in the 0 to 1 range)

## Performance

*ktrig* - output trigger signal

*kfreq* - frequency of trigger bangs in cps

*metro* is a simple opcode that outputs a sequence of isochronous bangs (that is 1 values) each 1/*kfreq* seconds. Trigger signals can be used in any circumstance, mainly to temporize realtime algorithmic compositional structures.

### Note

*metro* will produce a trigger signal of 1 when its phase is exactly 0 or 1. If you want to skip the initial trigger, use a very small value like 0.00000001.

## Examples

Here is an example of the metro opcode. It uses the file *metro.csd* [examples/metro.csd]

### Example 486. Example of the metro opcode.

```
<CsoundSynthesizer>
<CsOptions>

# midglobal

midglobal — An opcode which can be used to implement a remote midi orchestra. This opcode will broadcast the midi events to all the machines involved in the remote concert.

## Description

With the *midremot* and *midglobal* opcodes you are able to perform instruments on remote machines and control them from a master machine. The remote opcodes are implemented using the master/client model. All the machines involved contain the same orchestra but only the master machine contains the information of the midi score. During the performance the master machine sends the midi events to the clients. The midglobal opcode sends the events to all the machines involved in the remote concert. These machines are determined by the *midremot* definitions made above the *midglobal* command. To send events to only one machine use *midremot*.

## Syntax

```
midglobal isource, instrnum [,instrnum...]
```

## Initialization

*isource* -- a string that is the intended host computer (e.g. 192.168.0.100). This is the source host which generates the events of the given instrument(s) and sends it to all the machines involved in the remote concert.

*instrnum* -- a list of instrument numbers which will be played on the destination machines

## Examples

See the entry for *midremot* for an example of usage.

# midic14

midic14 — Allows a floating-point 14-bit MIDI signal scaled with a minimum and a maximum range.

## Description

Allows a floating-point 14-bit MIDI signal scaled with a minimum and a maximum range.

## Syntax

```
idest midic14 ictlno1, ictlno2, imin, imax [, ifn]
```

```
kdest midic14 ictlno1, ictlno2, kmin, kmax [, ifn]
```

## Initialization

*idest* -- output signal

*ictlno1* -- most-significant byte controller number (0-127)

*ictlno2* -- least-significant byte controller number (0-127)

*imin* -- user-defined minimum floating-point value of output

*imax* -- user-defined maximum floating-point value of output

*ifn* (optional) -- table to be read when indexing is required. Table must be normalized. Output is scaled according to *imin* and *imax* values.

## Performance

*kdest* -- output signal

*kmin* -- user-defined minimum floating-point value of output

*kmax* -- user-defined maximum floating-point value of output

*midic14* (i- and k-rate 14 bit MIDI control) allows a floating-point 14-bit MIDI signal scaled with a minimum and a maximum range. The minimum and maximum values can be varied at k-rate. It can use optional interpolated table indexing. It requires two MIDI controllers as input.

### Note

Please note that the *midic* family of opcodes are designed for MIDI triggered events, and don't require a channel number since they will respond to the same channel as the one that triggered the instrument (see *massign*). However they will crash if called from a score driven event.

Thanks goes to Rasmus Ekman for pointing out the correct controller number range.

# midic21

midic21 — Allows a floating-point 21-bit MIDI signal scaled with a minimum and a maximum range.

## Description

Allows a floating-point 21-bit MIDI signal scaled with a minimum and a maximum range.

## Syntax

```
idest midic21 ictlno1, ictlno2, ictlno3, imin, imax [, ifn]
```

```
kdest midic21 ictlno1, ictlno2, ictlno3, kmin, kmax [, ifn]
```

## Initialization

*idest* -- output signal

*ictlno1* -- most-significant byte controller number (0-127)

*ictlno2* -- mid-significant byte controller number (0-127)

*ictlno3* -- least-significant byte controller number (0-127)

*imin* -- user-defined minimum floating-point value of output

*imax* -- user-defined maximum floating-point value of output

*ifn* (optional) -- table to be read when indexing is required. Table must be normalized. Output is scaled according to the *imin* and *imax* values.

## Performance

*kdest* -- output signal

*kmin* -- user-defined minimum floating-point value of output

*kmax* -- user-defined maximum floating-point value of output

*midic21* (i- and k-rate 21 bit MIDI control) allows a floating-point 21-bit MIDI signal scaled with a minimum and a maximum range. Minimum and maximum values can be varied at k-rate. It can use optional interpolated table indexing. It requires three MIDI controllers as input.

### Note

Please note that the *midic* family of opcodes are designed for MIDI triggered events, and don't require a channel number since they will respond to the same channel as the one that triggered the instrument (see *massign*). However they will crash if called from a score driven event.

# midic7

midic7 — Allows a floating-point 7-bit MIDI signal scaled with a minimum and a maximum range.

## Description

Allows a floating-point 7-bit MIDI signal scaled with a minimum and a maximum range.

## Syntax

```
idest midic7 ictlno, imin, imax [, ifn]
```

```
kdest midic7 ictlno, kmin, kmax [, ifn]
```

## Initialization

*idest* -- output signal

*ictlno* -- MIDI controller number (0-127)

*imin* -- user-defined minimum floating-point value of output

*imax* -- user-defined maximum floating-point value of output

*ifn* (optional) -- table to be read when indexing is required. Table must be normalized. Output is scaled according to the *imin* and *imax* values.

## Performance

*kdest* -- output signal

*kmin* -- user-defined minimum floating-point value of output

*kmax* -- user-defined maximum floating-point value of output

*midic7* (i- and k-rate 7 bit MIDI control) allows a floating-point 7-bit MIDI signal scaled with a minimum and a maximum range. It also allows optional non-interpolated table indexing. In *midic7* minimum and maximum values can be varied at k-rate.

### Note

Please note that the *midic* family of opcodes are designed for MIDI triggered events, and don't require a channel number since they will respond to the same channel as the one that triggered the instrument (see *massign*). However they will crash if called from a score driven event.

## Examples

Here is an example of the midic7 opcode. It uses the file *midic7.csd* [examples/midic7.csd]

# midichannelaftertouch

`midichannelaftertouch` — Gets a MIDI channel's aftertouch value.

## Description

`midichannelaftertouch` is designed to simplify writing instruments that can be used interchangeably for either score or MIDI input, and to make it easier to adapt instruments originally written for score input to work with MIDI input.

In general, it should be possible to write instrument definitions that work identically with both scores and MIDI, including both MIDI files and real-time MIDI input, without using any conditional statements, and that take full advantage of MIDI voice messages.

Note that correlating Csound instruments with MIDI channel numbers is done using the `massign` opcode for real-time performance,. For file-driven performance, instrument numbers default to MIDI channel number + 1, but the defaults are overridden by any MIDI program change messages in the file.

## Syntax

```
midichannelaftertouch xchannelaftertouch [, ilow] [, ihigh]
```

## Initialization

*ilow* (optional) -- optional low value after rescaling, defaults to 0.

*ihigh* (optional) -- optional high value after rescaling, defaults to 127.

## Performance

*xchannelaftertouch* -- returns the MIDI channel aftertouch during MIDI activation, remains unchanged otherwise.

If the instrument was activated by MIDI input, the opcode overwrites the value of *xchannelaftertouch* with the corresponding value from MIDI input. If the instrument was *NOT* activated by MIDI input, the value of *xchannelaftertouch* remains unchanged.

This enables score p-fields to receive MIDI input data during MIDI activation, and score values otherwise.

### Adapting a score-activated Csound instrument.

See the *MIDI interop opcodes* section for details on adapting score driven instruments for MIDI or vice-versa.

## Examples

Here is an example of the midichannelaftertouch opcode. It uses the file *midichannelaftertouch.csd* [examples/midichannelaftertouch.csd].

**Example 489. Example of the midichannelaftertouch opcode.**

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>

# midichn

midichn — Returns the MIDI channel number from which the note was activated.

## Description

*midichn* returns the MIDI channel number (1 - 16) from which the note was activated. In the case of score notes, it returns 0.

## Syntax

```
ichn midichn
```

## Initialization

*ichn* -- channel number. If the current note was activated from score, it is set to zero.

## Examples

Here is a simple example of the midichn opcode. It uses the file *midichn.csd* [examples/midichn.csd].

### Example 490. Example of the midichn opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac -M0 -+rtmidi=virtual ;;; midi file input
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1

# midicontrolchange

midicontrolchange — Gets a MIDI control change value.

## Description

*midicontrolchange* is designed to simplify writing instruments that can be used interchangeably for either score or MIDI input, and to make it easier to adapt instruments originally written for score input to work with MIDI input.

In general, it should be possible to write instrument definitions that work identically with both scores and MIDI, including both MIDI files and real-time MIDI input, without using any conditional statements, and that take full advantage of MIDI voice messages.

Note that correlating Csound instruments with MIDI channel numbers is done using the *massign* opcode for real-time performance,. For file-driven performance, instrument numbers default to MIDI channel number + 1, but the defaults are overridden by any MIDI program change messages in the file.

## Syntax

```
midicontrolchange xcontroller, xcontrollervalue [, ilow] [, ihigh]
```

## Initialization

*ilow* (optional) -- optional low value after rescaling, defaults to 0.

*ihigh* (optional) -- optional high value after rescaling, defaults to 127.

## Performance

*xcontroller* -- specifies a MIDI controller number (0-127).

*xcontrollervalue* -- returns the value of the MIDI controller during MIDI activation, remains unchanged otherwise.

If the instrument was activated by MIDI input, the opcode overwrites the values of the *xcontroller* and *xcontrollervalue* with the corresponding values from MIDI input. If the instrument was *NOT* activated by MIDI input, the values of *xcontroller* and *xcontrollervalue* remain unchanged.

This enables score p-fields to receive MIDI input data during MIDI activation, and score values otherwise.

### Adapting a score-activated Csound instrument.

See the *MIDI interop opcodes* section for details on adapting score driven instruments for MIDI or vice-versa.

## Examples

Here is an example of the midicontrolchange opcode. It uses the file *midicontrolchange.csd* [examples/midicontrolchange.csd]

### Example 492. Example of the midicontrolchange opcode.

```

# midictrl

midictrl — Get the current value (0-127) of a specified MIDI controller.

## Description

Get the current value (0-127) of a specified MIDI controller.

## Syntax

```
ival midictrl inum [, imin] [, imax]
```

```
kval midictrl inum [, imin] [, imax]
```

## Initialization

*inum* -- MIDI controller number (0-127)

*imin, imax* -- set minimum and maximum limits on values obtained.

## Performance

Get the current value (0-127) of a specified MIDI controller.

## Warning

*midictrl* should only be used in notes that were triggered from MIDI, so that an associated channel number is available. For notes activated from the score, line events, or orchestra, the *ctrl7* opcode that takes an explicit channel number should be used instead.

## Examples

Here is an example of the midictrl opcode. It uses the file *midictrl.csd* [examples/midictrl.csd]

### Example 493. Example of the midictrl opcode.

```
<CsoundSynthesizer>

# mididefault

mididefault — Changes values, depending on MIDI activation.

## Description

*mididefault* is designed to simplify writing instruments that can be used interchangeably for either score or MIDI input, and to make it easier to adapt instruments originally written for score input to work with MIDI input.

In general, it should be possible to write instrument definitions that work identically with both scores and MIDI, including both MIDI files and real-time MIDI input, without using any conditional statements, and that take full advantage of MIDI voice messages.

Note that correlating Csound instruments with MIDI channel numbers is done using the *massign* opcode for real-time performance,. For file-driven performance, instrument numbers default to MIDI channel number + 1, but the defaults are overridden by any MIDI program change messages in the file.

## Syntax

```
mididefault xdefault, xvalue
```

## Performance

*xdefault* -- specifies a default value that will be used during MIDI activation.

*xvalue* -- overwritten by *xdefault* during MIDI activation, remains unchanged otherwise.

If the instrument was activated by MIDI input, the opcode will overwrite the value of *xvalue* with the value of *xdefault*. If the instrument was *NOT* activated by MIDI input, *xvalue* will remain unchanged.

This enables score pfields to receive a default value during MIDI activation, and score values otherwise.

### Adapting a score-activated Csound instrument.

See the *MIDI interop opcodes* section for details on adapting score driven instruments for MIDI or vice-versa.

## Examples

Here is an example of the mididefault opcode. It uses the file *mididefault.csd* [examples/mididefault.csd].

### Example 494. Example of the mididefault opcode.

# midiin

`midiin` — Returns a generic MIDI message received by the MIDI IN port.

## Description

Returns a generic MIDI message received by the MIDI IN port

## Syntax

```
kstatus, kchan, kdata1, kdata2 midiin
```

## Performance

*kstatus* -- the type of MIDI message. Can be:

- 128 (note off)
- 144 (note on)
- 160 (polyphonic aftertouch)
- 176 (control change)
- 192 (program change)
- 208 (channel aftertouch)
- 224 (pitch bend)
- 0 if no MIDI message are pending in the MIDI IN buffer

*kchan* -- MIDI channel (1-16)

*kdata1*, *kdata2* -- message-dependent data values

*midiin* has no input arguments, because it reads at the MIDI in port implicitly. It works at k-rate. Normally (i.e., when no messages are pending) *kstatus* is zero, only when MIDI data are present in the MIDI IN buffer, is *kstatus* set to the type of the relevant messages.

### Note

Be careful when using *midiin* in low numbered instruments, since a MIDI note will launch additional instances of the instrument, resulting in duplicate events and weird behaviour. Use *massign* to direct MIDI note on messages to a different instrument or to disable triggering of instruments from MIDI.

## Examples

Here is an example of the *midiin* opcode. It uses the file *midiin.csd* [examples/midiin.csd].

**Example 495. Example of the midiin opcode.**

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# midinoteoff

`midinoteoff` — Gets a MIDI noteoff value.

## Description

`midinoteoff` is designed to simplify writing instruments that can be used interchangeably for either score or MIDI input, and to make it easier to adapt instruments originally written for score input to work with MIDI input.

In general, it should be possible to write instrument definitions that work identically with both scores and MIDI, including both MIDI files and real-time MIDI input, without using any conditional statements, and that take full advantage of MIDI voice messages.

Note that correlating Csound instruments with MIDI channel numbers is done using the `massign` opcode for real-time performance,. For file-driven performance, instrument numbers default to MIDI channel number + 1, but the defaults are overridden by any MIDI program change messages in the file.

## Syntax

```
midinoteoff xkey, xvelocity
```

## Performance

`xkey` -- returns MIDI key during MIDI activation, remains unchanged otherwise.

`xvelocity` -- returns MIDI velocity during MIDI activation, remains unchanged otherwise.

If the instrument was activated by MIDI input, the opcode overwrites the values of the `xkey` and `xvelocity` with the corresponding values from MIDI input. If the instrument was *NOT* activated by MIDI input, the values of `xkey` and `xvelocity` remain unchanged.

This enables score p-fields to receive MIDI input data during MIDI activation, and score values otherwise.

### Adapting a score-activated Csound instrument.

See the *MIDI interop opcodes* section for details on adapting score driven instruments for MIDI or vice-versa.

## Examples

Here is an example of the `midinoteoff` opcode. It uses the file `midinoteoff.csd` [examples/midinoteoff.csd].

### Example 496. Example of the midinoteoff opcode.

# midinoteoncps

`midinoteoncps` — Gets a MIDI note number as a cycles-per-second frequency.

## Description

`midinoteoncps` is designed to simplify writing instruments that can be used interchangeably for either score or MIDI input, and to make it easier to adapt instruments originally written for score input to work with MIDI input.

In general, it should be possible to write instrument definitions that work identically with both scores and MIDI, including both MIDI files and real-time MIDI input, without using any conditional statements, and that take full advantage of MIDI voice messages.

Note that correlating Csound instruments with MIDI channel numbers is done using the `massign` opcode for real-time performance,. For file-driven performance, instrument numbers default to MIDI channel number + 1, but the defaults are overridden by any MIDI program change messages in the file.

## Syntax

```
midinoteoncps  xcps,  xvelocity
```

## Performance

`xcps` -- returns MIDI key translated to cycles per second during MIDI activation, remains unchanged otherwise.

`xvelocity` -- returns MIDI velocity during MIDI activation, remains unchanged otherwise.

If the instrument was activated by MIDI input, the opcode overwrites the values of `xcps` and `xvelocity` with the corresponding values from MIDI input. If the instrument was *NOT* activated by MIDI input, the values of `xcps` and `xvelocity` remain unchanged.

This enables score p-fields to receive MIDI input data during MIDI activation, and score values otherwise.

### Adapting a score-activated Csound instrument.

See the *MIDI interop opcodes* section for details on adapting score driven instruments for MIDI or vice-versa.

## Examples

# midinoteonkey

`midinoteonkey` — Gets a MIDI note number value.

## Description

`midinoteonkey` is designed to simplify writing instruments that can be used interchangeably for either score or MIDI input, and to make it easier to adapt instruments originally written for score input to work with MIDI input.

In general, it should be possible to write instrument definitions that work identically with both scores and MIDI, including both MIDI files and real-time MIDI input, without using any conditional statements, and that take full advantage of MIDI voice messages.

Note that correlating Csound instruments with MIDI channel numbers is done using the `massign` opcode for real-time performance,. For file-driven performance, instrument numbers default to MIDI channel number + 1, but the defaults are overridden by any MIDI program change messages in the file.

## Syntax

```
midinoteonkey xkey, xvelocity
```

## Performance

*xkey* -- returns MIDI key during MIDI activation, remains unchanged otherwise.

*xvelocity* -- returns MIDI velocity during MIDI activation, remains unchanged otherwise.

If the instrument was activated by MIDI input, the opcode overwrites the values of *xkey* and *xvelocity* with the corresponding values from MIDI input. If the instrument was *NOT* activated by MIDI input, the values of *xkey* and *xvelocity* remain unchanged.

This enables score p-fields to receive MIDI input data during MIDI activation, and score values otherwise.

### Adapting a score-activated Csound instrument.

See the *MIDI interop opcodes* section for details on adapting score driven instruments for MIDI or vice-versa.

## Examples

Here is an example of the `midinoteonkey` opcode. It uses the file `midinoteonkey.csd` [examples/`midinoteonkey.csd`].

### Example 498. Example of the midinoteonkey opcode.

# midinoteonoct

`midinoteonoct` — Gets a MIDI note number value as octave-point-decimal value.

## Description

`midinoteonoct` is designed to simplify writing instruments that can be used interchangeably for either score or MIDI input, and to make it easier to adapt instruments originally written for score input to work with MIDI input.

In general, it should be possible to write instrument definitions that work identically with both scores and MIDI, including both MIDI files and real-time MIDI input, without using any conditional statements, and that take full advantage of MIDI voice messages.

Note that correlating Csound instruments with MIDI channel numbers is done using the `massign` opcode for real-time performance,. For file-driven performance, instrument numbers default to MIDI channel number + 1, but the defaults are overridden by any MIDI program change messages in the file.

## Syntax

```
midinoteonoct  xoct,  xvelocity
```

## Performance

`xoct` -- returns MIDI key translated to linear octaves during MIDI activation, remains unchanged otherwise.

`xvelocity` -- returns MIDI velocity during MIDI activation, remains unchanged otherwise.

If the instrument was activated by MIDI input, the opcode overwrites the values of `xoct` and `xvelocity` with the corresponding value from MIDI input. If the instrument was *NOT* activated by MIDI input, the values of `xoct` and `xvelocity` remain unchanged.

This enables score p-fields to receive MIDI input data during MIDI activation, and score values otherwise.

### Adapting a score-activated Csound instrument.

See the *MIDI interop opcodes* section for details on adapting score driven instruments for MIDI or vice-versa.

## Examples

Here is an example of the `midinoteonoct` opcode. It uses the file `midinoteonoct.csd` [examples/midinoteonoct.csd].

### Example 499. Example of the midinoteonoct opcode.

# midinoteonpch

`midinoteonpch` — Gets a MIDI note number as a pitch-class value.

## Description

`midinoteonpch` is designed to simplify writing instruments that can be used interchangeably for either score or MIDI input, and to make it easier to adapt instruments originally written for score input to work with MIDI input.

In general, it should be possible to write instrument definitions that work identically with both scores and MIDI, including both MIDI files and real-time MIDI input, without using any conditional statements, and that take full advantage of MIDI voice messages.

Note that correlating Csound instruments with MIDI channel numbers is done using the `massign` opcode for real-time performance,. For file-driven performance, instrument numbers default to MIDI channel number + 1, but the defaults are overridden by any MIDI program change messages in the file.

## Syntax

```
midinoteonpch xpch, xvelocity
```

## Performance

*xpch* -- returns MIDI key translated to octave.pch during MIDI activation, remains unchanged otherwise.

*xvelocity* -- returns MIDI velocity during MIDI activation, remains unchanged otherwise.

If the instrument was activated by MIDI input, the opcode overwrites the values of *xpch* and *xvelocity* with the corresponding value from MIDI input. If the instrument was *NOT* activated by MIDI input, the values of *xpch* and *xvelocity* remain unchanged.

This enables score p-fields to receive MIDI input data during MIDI activation, and score values otherwise.

### Adapting a score-activated Csound instrument.

See the *MIDI interop opcodes* section for details on adapting score driven instruments for MIDI or vice-versa.

## Examples

Here is an example of the `midinoteonpch` opcode. It uses the file `midinoteonpch.csd` [examples/`midinoteonpch.csd`].

### Example 500. Example of the `midinoteonpch` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# midion2

midion2 — Sends noteon and noteoff messages to the MIDI OUT port.

## Description

Sends noteon and noteoff messages to the MIDI OUT port when triggered by a value different than zero.

## Syntax

```
midion2 kchn, knum, kvel, ktrig
```

## Performance

*kchn* -- MIDI channel (1-16)

*knum* -- MIDI note number (0-127)

*kvel* -- note velocity (0-127)

*ktrig* -- trigger input signal (normally 0)

Similar to *midion*, this opcode sends noteon and noteoff messages to the MIDI out port, but only when *ktrig* is non-zero. This opcode is can work together with the output of the *trigger* opcode.

## Examples

Here is an example of the midion2 opcode. It uses the file *midion2.csd* [examples/midion2.csd].

### Example 501. Example of the midion2 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# midion

**midion** — Generates MIDI note messages at k-rate.

## Description

Generates MIDI note messages at k-rate.

## Syntax

```
midion kchn, knum, kvel
```

## Performance

*kchn* -- MIDI channel number (1-16)

*knum* -- note number (0-127)

*kvel* -- velocity (0-127)

*midion* (k-rate note on) plays MIDI notes with current *kchn*, *knum* and *kvel*. These arguments can be varied at k-rate. Each time the MIDI converted value of any of these arguments changes, last MIDI note played by current instance of *midion* is immediately turned off and a new note with the new argument values is activated. This opcode, as well as *moscil*, can generate very complex melodic textures if controlled by complex k-rate signals.

Any number of *midion* opcodes can appear in the same Csound instrument, allowing a counterpoint-style polyphony within a single instrument.

## Examples

Here is a simple example of the *midion* opcode. It uses the file *midion\_simple.csd* [examples/midi-on\_simple.csd].

### Example 502. Simple Example of the midion opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

This example generates a minor chord over every note received on the MIDI input. It generates MIDI notes on csound's MIDI output, so be sure to connect something.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform

# midiout

`midiout` — Sends a generic MIDI message to the MIDI OUT port.

## Description

Sends a generic MIDI message to the MIDI OUT port.

## Syntax

```
midiout kstatus, kchan, kdata1, kdata2
```

## Performance

*kstatus* -- the type of MIDI message. Can be:

- 128 (note off)
- 144 (note on)
- 160 (polyphonic aftertouch)
- 176 (control change)
- 192 (program change)
- 208 (channel aftertouch)
- 224 (pitch bend)
- 0 when no MIDI messages must be sent to the MIDI OUT port

*kchan* -- MIDI channel (1-16)

*kdata1*, *kdata2* -- message-dependent data values

*midiout* has no output arguments, because it sends a message to the MIDI OUT port implicitly. It works at k-rate. It sends a MIDI message only when *kstatus* is non-zero.

### Warning

*Warning:* Normally *kstatus* should be set to 0. Only when the user intends to send a MIDI message, can it be set to the corresponding message type number.

## Examples

Here is an example of the midiout opcode. It uses the file *midiout.csd* [examples/midiout.csd].

### Example 504. Example of the midiout opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# midipitchbend

`midipitchbend` — Gets a MIDI pitchbend value.

## Description

`midipitchbend` is designed to simplify writing instruments that can be used interchangeably for either score or MIDI input, and to make it easier to adapt instruments originally written for score input to work with MIDI input.

In general, it should be possible to write instrument definitions that work identically with both scores and MIDI, including both MIDI files and real-time MIDI input, without using any conditional statements, and that take full advantage of MIDI voice messages.

Note that correlating Csound instruments with MIDI channel numbers is done using the `massign` opcode for real-time performance,. For file-driven performance, instrument numbers default to MIDI channel number + 1, but the defaults are overridden by any MIDI program change messages in the file.

## Syntax

```
midipitchbend xpitchbend [, ilow] [, ihigh]
```

## Initialization

*ilow* (optional) -- optional low value after rescaling, defaults to 0.

*ihigh* (optional) -- optional high value after rescaling, defaults to 127.

## Performance

*xpitchbend* -- returns the MIDI pitch bend during MIDI activation, remains unchanged otherwise.

If the instrument was activated by MIDI input, the opcode overwrites the value of *xpitchbend* with the corresponding value from MIDI input. If the instrument was *NOT* activated by MIDI input, the value of *xpitchbend* remains unchanged.

This enables score p-fields to receive MIDI input data during MIDI activation, and score values otherwise.

### Adapting a score-activated Csound instrument.

See the *MIDI interop opcodes* section for details on adapting score driven instruments for MIDI or vice-versa.

## Examples

Here is an example of the `midipitchbend` opcode. It uses the file `midipitchbend.csd` [examples/`midipitchbend.csd`].

### Example 505. Example of the midipitchbend opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# midipolyaftertouch

`midipolyaftertouch` — Gets a MIDI polyphonic aftertouch value.

## Description

`midipolyaftertouch` is designed to simplify writing instruments that can be used interchangeably for either score or MIDI input, and to make it easier to adapt instruments originally written for score input to work with MIDI input.

In general, it should be possible to write instrument definitions that work identically with both scores and MIDI, including both MIDI files and real-time MIDI input, without using any conditional statements, and that take full advantage of MIDI voice messages.

Note that correlating Csound instruments with MIDI channel numbers is done using the `massign` opcode for real-time performance,. For file-driven performance, instrument numbers default to MIDI channel number + 1, but the defaults are overridden by any MIDI program change messages in the file.

## Syntax

```
midipolyaftertouch xpolyaftertouch, xcontrollervalue [, ilow] [, ihigh]
```

## Initialization

*ilow* (optional) -- optional low value after rescaling, defaults to 0.

*ihigh* (optional) -- optional high value after rescaling, defaults to 127.

## Performance

*xpolyaftertouch* -- returns MIDI polyphonic aftertouch during MIDI activation, remains unchanged otherwise.

*xcontrollervalue* -- returns the value of the MIDI controller during MIDI activation, remains unchanged otherwise.

If the instrument was activated by MIDI input, the opcode overwrites the values of *xpolyaftertouch* and *xcontrollervalue* with the corresponding values from MIDI input. If the instrument was *NOT* activated by MIDI input, the values of *xpolyaftertouch* and *xcontrollervalue* remain unchanged.

This enables score p-fields to receive MIDI input data during MIDI activation, and score values otherwise.

### Adapting a score-activated Csound instrument.

See the *MIDI interop opcodes* section for details on adapting score driven instruments for MIDI or vice-versa.

## Examples

Here is an example of the `midipolyaftertouch` opcode. It uses the file `midipolyaftertouch.csd` [examples/

midipolyaftertouch.csd].

### Example 506. Example of the midipolyaftertouch opcode.

# midiprogramchange

`midiprogramchange` — Gets a MIDI program change value.

## Description

`midiprogramchange` is designed to simplify writing instruments that can be used interchangeably for either score or MIDI input, and to make it easier to adapt instruments originally written for score input to work with MIDI input.

In general, it should be possible to write instrument definitions that work identically with both scores and MIDI, including both MIDI files and real-time MIDI input, without using any conditional statements, and that take full advantage of MIDI voice messages.

Note that correlating Csound instruments with MIDI channel numbers is done using the `massign` opcode for real-time performance,. For file-driven performance, instrument numbers default to MIDI channel number + 1, but the defaults are overridden by any MIDI program change messages in the file.

## Syntax

```
midiprogramchange xprogram
```

## Performance

*xprogram* -- returns the MIDI program change value during MIDI activation, remains unchanged otherwise.

If the instrument was activated by MIDI input, the opcode overwrites the value of *xprogram* with the corresponding value from MIDI input. If the instrument was *NOT* activated by MIDI input, the value of *xprogram* remains unchanged.

This enables score p-fields to receive MIDI input data during MIDI activation, and score values otherwise.

### Adapting a score-activated Csound instrument.

See the *MIDI interop opcodes* section for details on adapting score driven instruments for MIDI or vice-versa.

## Examples

Here is an example of the `midiprogramchange` opcode. It uses the file `midiprogramchange.csd` [examples/midiprogramchange.csd].

# midremot

**midremot** — An opcode which can be used to implement a remote midi orchestra. This opcode will send midi events from a source machine to one destination.

## Description

With the *midremot* and *midglobal* opcodes you are able to perform instruments on remote machines and control them from a master machine. The remote opcodes are implemented using the master/client model. All the machines involved contain the same orchestra but only the master machine contains the information of the midi score. During the performance the master machine sends the midi events to the clients. The *midremot* opcode will send events from a source machine to one destination if you want to send events to many destinations (broadcast) use the *midglobal* opcode instead. These two opcodes can be used in combination.

## Syntax

```
midremot idestination, isource, instrnum [,instrnum...]
```

## Initialization

*idestination* -- a string that is the intended host computer (e.g. 192.168.0.100). This is the destination host which receives the events from the given instrument.

*isource* -- a string that is the intended host computer (e.g. 192.168.0.100). This is the source host which generates the events of the given instrument and sends it to the address given by *idestination*.

*instrnum* -- a list of instrument numbers which will be played on the destination machine

## Examples

Here is an example of the midremot opcode. It uses the files *insremot.csd* [examples/midremot.csd].

### Example 509. Example of the insremot opcode.

The example shows a Bach fugue played on 4 remote computers. The master machine is named "192.168.1.100", client1 "192.168.1.101" and so on. Start the clients on each machine (they will be waiting to receive the events from the master machine) and then start the master. Here is the command on linux to start a client (csound -dm0 -odac -+rtaudio=alsa midremot.csd -+rtmidi=NULL), and the command on the master machine will look like this (csound -dm0 -odac -+rtaudio=alsa midremot.csd -F midremot.mid).

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# min

**min** — Produces a signal that is the minimum of any number of input signals.

## Description

The *min* opcode takes any number of a-rate, k-rate or i-rate signals as input (all of the same rate), and outputs a signal at the same rate that is the minimum of all of the inputs. For a-rate signals, the inputs are compared one sample at a time (i.e. *min* does not scan an entire ksmps period of a signal for its local minimum as the *max\_k* opcode does).

## Syntax

```
amin min ain1, ain2 [, ain3] [, ain4] [...]  
  
kmin min kin1, kin2 [, kin3] [, kin4] [...]  
  
imin min iin1, iin2 [, iin3] [, iin4] [...]
```

## Performance

*ain1, ain2, ...* -- a-rate signals to be compared.

*kin1, kin2, ...* -- k-rate signals to be compared.

*iin1, iin2, ...* -- i-rate signals to be compared.

## Examples

Here is an example of the *min* opcode. It uses the file *min.csd* [examples/min.csd].

### Example 510. Example of the min opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# minabs

**minabs** — Produces a signal that is the minimum of the absolute values of any number of input signals.

## Description

The *minabs* opcode takes any number of a-rate or k-rate signals as input (all of the same rate), and outputs a signal at the same rate that is the minimum of all of the inputs. It is identical to the *min* opcode except that it takes the absolute value of each input before comparing them. Therefore, the output is always non-negative. For a-rate signals, the inputs are compared one sample at a time (i.e. *minabs* does not scan an entire ksmpls period of a signal for its local minimum as the *max\_k* opcode does).

## Syntax

```
amin minabs ain1, ain2 [, ain3] [, ain4] [...]  
  
kmin minabs kin1, kin2 [, kin3] [, kin4] [...]
```

## Performance

*ain1, ain2, ...* -- a-rate signals to be compared.

*kin1, kin2, ...* -- k-rate signals to be compared.

## Examples

Here is an example of the minabs opcode. It uses the file *minabs.csd* [examples/minabs.csd].

### Example 511. Example of the minabs opcode.

# minabsaccum

`minabsaccum` — Accumulates the minimum of the absolute values of audio signals.

## Description

*minabsaccum* compares two audio-rate variables and stores the minimum of their absolute values into the first.

## Syntax

```
minabsaccum aAccumulator, aInput
```

## Performance

*aAccumulator* -- audio variable to store the minimum value

*aInput* -- signal that *aAccumulator* is compared to

The *minabsaccum* opcode is designed to accumulate the minimum value from among many audio signals that may be in different note instances, different channels, or otherwise cannot all be compared at once using the *minabs* opcode. *minabsaccum* is identical to *minaccum* except that it takes the absolute value of *aInput* before the comparison. Its semantics are similar to *vincr* since *aAccumulator* is used as both an input and an output variable, except that *minabsaccum* keeps the minimum absolute value instead of adding the signals together. *minabsaccum* performs the following operation on each pair of samples:

```
if (abs(aInput) < aAccumulator) aAccumulator = abs(aInput)
```

*aAccumulator* will usually be a global audio variable. At the end of any given computation cycle (k-period), after its value is read and used in some way, the accumulator variable should usually be reset to some large enough positive value that will always be greater than the input signals to which it is compared.

## Examples

Here is an example of the *minabsaccum* opcode. It uses the file *minabsaccum.csd* [examples/minabsaccum.csd].

### Example 512. Example of the minabsaccum opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# mincer

*mincer* — Phase-locked vocoder processing.

## Description

*mincer* implements phase-locked vocoder processing using function tables containing sampled-sound sources, with *GEN01*, and *mincer* will accept deferred allocation tables.

This opcode allows for time and frequency-independent scaling. Time is controlled by a time index (in seconds) to the function table position and can be moved forward and backward at any chosen speed, as well as stopped at a given position ("frozen"). The quality of the effect is generally improved with phase locking switched on.

*mincer* will also scale pitch, independently of frequency, using a transposition factor (k-rate).

## Syntax

```
asig mincer atimpt, kamp, kpitch, ktab, klock[,ifftsize,idecim]
```

## Initialization

*ifftsize* -- FFT size (power-of-two), defaults to 2048.

*idecim* -- decimation, defaults to 4 (meaning hopsize = fftsize/4)

## Performance

*atimpt* -- time position of current audio sample in secs. Table reading wraps around the ends of the function table.

*kamp* -- amplitude scaling

*kpitch* -- grain pitch scaling (1=normal pitch, < 1 lower, > 1 higher; negative, backwards)

*klock* -- 0 or 1, to switch phase-locking on/off

*ktab* -- source signal function table. Deferred-allocation tables (see *GEN01*) are accepted, but the opcode expects a mono source. Tables can be switched at k-rate.

## Examples

Here is an example of the *mincer* opcode. It uses the file *mincer.csd* [examples/mincer.csd]

### Example 514. Example of the *mincer* opcode.

# mirror

**mirror** — Reflects the signal that exceeds the low and high thresholds.

## Description

Reflects the signal that exceeds the low and high thresholds.

## Syntax

```
ares mirror asig, klow, khig  
  
ires mirror isig, ilow, ihigh  
  
kres mirror ksig, klow, khig
```

## Initialization

*isig* -- input signal  
*ilow* -- low threshold  
*ihigh* -- high threshold

## Performance

*xsig* -- input signal  
*klow* -- low threshold  
*khig* -- high threshold  
*mirror* “reflects” the signal that exceeds the low and high thresholds.

This opcode is useful in several situations, such as table indexing or for clipping and modeling a-rate, i-rate or k-rate signals.

## Examples

Here is an example of the mirror opcode. It uses the file *mirror.csd* [examples/mirror.csd].

### Example 516. Example of the mirror opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# MixerSetLevel

MixerSetLevel — Sets the level of a send to a buss.

## Syntax

```
MixerSetLevel isend, ibuss, kgain
```

## Description

Sets the level at which signals from the send are added to the buss. The actual sending of the signal to the buss is performed by the *MixerSend* opcode.

## Initialization

*isend* -- The number of the send, for example the number of the instrument sending the signal (but any integer can be used).

*ibuss* -- The number of the buss, for example the number of the instrument receiving the signal (but any integer can be used).

Setting the gain for a buss also creates the buss.

## Performance

*kgain* -- The level (any real number) at which the signal from the send will be mixed onto the buss. The default is 0.

Use of the mixer requires that instruments setting gains have smaller numbers than instruments sending signals, and that instruments sending signals have smaller numbers than instruments receiving those signals. However, an instrument may have any number of sends or receives. After the final signal is received, *MixerClear* must be invoked to reset the busses before the next kperiod.

## Examples

In the orchestra, define an instrument to control mixer levels:

```
instr 1
    MixerSetLevel      p4, p5, p6
endin
```

In the score, use that instrument to set mixer levels:

```
; SoundFonts
; to Chorus
i 1 0 0 100 200 0.9
; to Reverb
i 1 0 0 100 210 0.7
; to Output
i 1 0 0 100 220 0.3

; Kelley Harpsichord
; to Chorus
i 1 0 0 3 200 0.30
; to Reverb
```

```
i 1 0 0 3 210 0.9
; to Output
i 1 0 0 3 220 0.1

; Chorus to Reverb
i 1 0 0 200 210 0.5
; Chorus to Output
i 1 0 0 200 220 0.5
; Reverb to Output
i 1 0 0 210 220 0.2
```

Here is a complete example of the MixerSetLevel opcode. It uses the file *Mixer.csd* [examples/Mixer.csd]

### Example 517. Complete example of the MixerSetLevel opcode.

# MixerSetLevel\_i

MixerSetLevel\_i — Sets the level of a send to a buss.

## Syntax

```
MixerSetLevel_i isend, ibuss, igain
```

## Description

Sets the level at which signals from the send are added to the buss. This opcode, because all parameters are irate, may be used in the orchestra header. The actual sending of the signal to the buss is performed by the *MixerSend* opcode.

## Initialization

*isend* -- The number of the send, for example the number of the instrument sending the signal (but any integer can be used).

*ibuss* -- The number of the buss, for example the number of the instrument receiving the signal (but any integer can be used).

*igain* -- The level (any real number) at which the signal from the send will be mixed onto the buss. The default is 0.

Setting the gain for a buss also creates the buss.

## Performance

Use of the mixer requires that instruments setting gains have smaller numbers than instruments sending signals, and that instruments sending signals have smaller numbers than instruments receiving those signals. However, an instrument may have any number of sends or receives. After the final signal is received, *MixerClear* must be invoked to reset the busses before the next kperiod.

## Examples

In the orchestra header, set the gain for the send from buss 3 to buss 4:

```
MixerSetLevel_i      3, 4, 0.76
```

# MixerGetLevel

MixerGetLevel — Gets the level of a send to a buss.

## Syntax

```
kgain MixerGetLevel isend, ibuss
```

## Description

Gets the level at which signals from the send are being added to the buss. The actual sending of the signal to the buss is performed by the *MixerSend* opcode.

## Initialization

*isend* -- The number of the send, for example the number of the instrument sending the signal.

*ibuss* -- The number of the buss, for example the number of the instrument receiving the signal.

## Performance

*kgain* -- The level (any real number) at which the signal from the send will be mixed onto the buss.

This opcode reports the level set by *MixerSetLevel* for a send and buss pair.

Use of the mixer requires that instruments setting gains have smaller numbers than instruments sending signals, and that instruments sending signals have smaller numbers than instruments receiving those signals. However, an instrument may have any number of sends or receives. After the final signal is received, *MixerClear* must be invoked to reset the busses to 0 before the next kperiod.

## Examples

Here is an example of the MixerGetLevel opcode. It uses the file *Mixer.csd* [examples/Mixer.csd]

### Example 518. Example of the MixerGetLevel opcode.
