# MixerSend

MixerSend — Mixes an arate signal into a channel of a buss.

## Syntax

```
MixerSend asignal, isend, ibuss, ichannel
```

## Description

Mixes an arate signal into a channel of a buss.

## Initialization

*isend* -- The number of the send, for example the number of the instrument sending the signal. The gain of the send is controlled by the *MixerSetLevel* opcode. The reason that the sends are numbered is to enable different levels for different sends to be set independently of the actual level of the signals.

*ibuss* -- The number of the buss, for example the number of the instrument receiving the signal.

*ichannel* -- The number of the channel. Each buss has *nchnls* channels.

## Performance

*asignal* -- The signal that will be mixed into the indicated channel of the buss.

Use of the mixer requires that instruments setting gains have smaller numbers than instruments sending signals, and that instruments sending signals have smaller numbers than instruments receiving those signals. However, an instrument may have any number of sends or receives. After the final signal is received, *MixerClear* must be invoked to reset the busses to 0 before the next kperiod.

## Examples

```
instr 100 ; Fluidsynth output
; INITIALIZATION
; Normalize so iamplitude for p5 of 80 == ampdb(80).
iamplitude          =           ampdb(p5) * 2.0
; AUDIO
aleft, aright      =           fluidAllOut      giFluidsynth
asig1               =           aleft * iamplitude
asig2               =           aright * iamplitude
; To the chorus.
MixerSend           asig1, 100, 200, 0
MixerSend           asig2, 100, 200, 1
; To the reverb.
MixerSend           asig1, 100, 210, 0
MixerSend           asig2, 100, 210, 1
; To the output.
MixerSend           asig1, 100, 220, 0
MixerSend           asig2, 100, 220, 1
endin
```

Here is a complete example of the MixerSend opcode. It uses the file *Mixer.csd* [examples/Mixer.csd]

# MixerReceive

MixerReceive — Receives an arate signal from a channel of a buss.

## Syntax

```
asignal MixerReceive ibuss, ichannel
```

## Description

Receives an arate signal that has been mixed onto a channel of a buss.

## Initialization

*ibuss* -- The number of the buss, for example the number of the instrument receiving the signal.

*ichannel* -- The number of the channel. Each buss has `nchnls` channels.

## Performance

*asignal* -- The signal that has been mixed onto the indicated channel of the buss.

Use of the mixer requires that instruments setting gains have smaller numbers than instruments sending signals, and that instruments sending signals have smaller numbers than instruments receiving those signals. However, an instrument may have any number of sends or receives. After the final signal is received, *MixerClear* must be invoked to reset the busses to 0 before the next kperiod.

## Examples

# mode

mode — A filter that simulates a mass-spring-damper system

## Description

Filters the incoming signal with the specified resonance frequency and quality factor. It can also be seen as a signal generator for high quality factor, with an impulse for the excitation. You can combine several modes to built complex instruments such as bells or guitar tables.

## Syntax

```
aout mode ain, xfreq, xQ [, iskip]
```

## Initialization

*iskip* (optional, default=0) -- if non zero skip the initialisation of the filter.

## Performance

*aout* -- filtered signal

*ain* -- signal to filter

*xfreq* -- resonant frequency of the filter

### Warning

This filter becomes unstable if  $sr/xfreq < \pi$  (e.g.  $xfreq > 14037$  Hz @ 44 kHz)

*xQ* -- quality factor of the filter

The resonance time is roughly proportional to  $xQ/xfreq$ .

See *Modal Frequency Ratios* for frequency ratios of real instruments which can be used to determine the values of *xfreq*.

## Examples

Here is an example of the mode opcode. It uses the file *mode.csd* [examples/mode.csd].

### Example 522. Example of the mode opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# modmatrix

modmatrix — Modulation matrix opcode with optimizations for sparse matrices.

## Description

The opcode can be used to let a large number of k-rate modulator variables modulate a large number of k-rate parameter variables, with arbitrary scaling of each modulator-to-parameter connection. Csound ftables are used to hold both the input (parameter) variables, the modulator variables, and the scaling coefficients. Output variables are written to another Csound ftable.

## Syntax

```
modmatrix iresfn, isrcmodfn, isrcparmfn, imodscale, inum_mod, \\
inum_parm, kupdate
```

## Initialization

*iresfn* -- ftable number for the parameter output variables

*isrcmodfn* -- ftable number for the modulation source variables

*isrcparmfn* -- ftable number for the parameter input variables

*imodscale* -- scaling/routing coefficient matrix. This is also a csound ftable, used as a matrix of *inum\_mod* rows and *inum\_parm* columns.

*inum\_mod* -- number of modulation variables

*inum\_parm* -- number of parameter (input and output) variables.

The arguments *inum\_mod* and *inum\_parm* do not have to be set to power-of-two values.

## Performance

*kupdate* -- flag to update the scaling coefficients. When the flag is set to a nonzero value, the scaling coefficients are read directly from the *imodscale* ftable. When the flag is set to zero, the scaling coefficients are scanned, and an optimized scaling matrix stored internally in the opcode.

For each modulator in *isrcmodfn*, scale it with the coefficient (in *imodscale*) determining to what degree it should influence each parameter. Then sum all modulators for each parameter and add the resulting modulator value to the input parameter value read from *isrcparmfn*. Finally, write the output parameter values to table *iresfn*.

The following tables give insight into the processing performed by the modmatrix opcode, for a simplified example using 3 parameter and 2 modulators. Let's call the parameters "cps1", "cps2", and "cutoff", and the modulators "lfo1" and "lfo2".

The input variables may at a given point in time have these values:

**Table 12.**

|                   | <b>cps1</b> | <b>cps2</b> | <b>cutoff</b> |
|-------------------|-------------|-------------|---------------|
| <i>isrcparmfn</i> | 400         | 800         | 3             |

... while the modulator variables have these values:

**Table 13.**

|                  | <b>lfo1</b> | <b>lfo2</b> |
|------------------|-------------|-------------|
| <i>isrcmodfn</i> | 0.5         | -0.2        |

The scaling/routing coefficients used:

**Table 14.**

| <i>imodscale</i> | <b>cps1</b> | <b>cps2</b> | <b>cutoff</b> |
|------------------|-------------|-------------|---------------|
| <i>lfo1</i>      | 40          | 0           | -2            |
| <i>lfo2</i>      | -50         | 100         | 3             |

... and the resulting output values:

**Table 15.**

|                | <b>cps1</b> | <b>cps2</b> | <b>cutoff</b> |
|----------------|-------------|-------------|---------------|
| <i>ireshfn</i> | 430         | 780         | 1.4           |
| <i>lfo2</i>    | -50         | 100         | 3             |

The output value for "cps1" is calculated as  $400 + (0.5 * 40) + (-0.2 * -50)$ , similarly for "cps2"  $800 + (0.5 * 0) + (-0.2 * 100)$ , and for cutoff:  $3 + (0.5 * -2) + (-0.2 * 3)$

The imodscale ftable may be specified in the score like this:

```
f1 0 8 -2 200 0 2 50 300 -1.5
```

Or more conveniently using *ftgen* in the orchestra:

```
gimodscale ftgen 0, 0, 8, -2, 200, 0, 2, 50, 300, -1.5
```

Obviously, the parameter and modulator variables need not be static values, and similarly, the scaling/routing coefficient table may be continuously rewritten using opcodes like *tablew*.

## Examples

Here is an example of the modmatrix opcode. It uses the file *modmatrix.csd* [examples/modmatrix.csd].

# monitor

monitor — Returns the audio spout frame.

## Description

Returns the audio spout frame (if active), otherwise it returns zero.

## Syntax

```
aout1 [,aout2 ... aoutX] monitor
```

## Performance

This opcode can be used for monitoring the output signal from csound. It should not be used for processing the signal further.

See the entry for the *fout* opcode for an example of usage of *monitor*.

## Examples

Here is an example of the monitor opcode. It uses the file *monitor.csd* [examples/monitor.csd].

### Example 524. Example of the monitor opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# moog

moog — An emulation of a mini-Moog synthesizer.

## Description

An emulation of a mini-Moog synthesizer.

## Syntax

```
ares moog kamp, kfreq, kfiltq, kfiltrate, kvibf, kvamp, iafn, iwfn, ivfn
```

## Initialization

*iafn*, *iwfn*, *ivfn* -- three table numbers containing the attack waveform (unlooped), the main looping waveform, and the vibrato waveform. The files *mandpluk.aiff* [examples/mandpluk.aiff] and *impuls20.aiff* [examples/impuls20.aiff] are suitable for the first two, and a sine wave for the last.

### Note

The files “*mandpluk.aiff*” and “*impuls20.aiff*” are also available at <ftp://ftp.cs.bath.ac.uk/pub/dream/documentation/sounds/modelling/>.

## Performance

*kamp* -- Amplitude of note.

*kfreq* -- Frequency of note played.

*kfiltq* -- Q of the filter, in the range 0.8 to 0.9

*kfiltrate* -- rate control for the filter in the range 0 to 0.0002

*kvibf* -- frequency of vibrato in Hertz. Suggested range is 0 to 12

*kvamp* -- amplitude of the vibrato

## Examples

Here is an example of the moog opcode. It uses the file *moog.csd* [examples/moog.csd], *mandpluk.aiff* [examples/mandpluk.aiff], and *impuls20.aiff* [examples/impuls20.aiff].

### Example 525. Example of the moog opcode.

# moogladder

moogladder — Moog ladder lowpass filter.

## Description

Moogladder is a new digital implementation of the Moog ladder filter based on the work of Antti Huovilainen, described in the paper "Non-Linear Digital Implementation of the Moog Ladder Filter" (Proceedings of DaFX04, Univ of Napoli). This implementation is probably a more accurate digital representation of the original analogue filter.

## Syntax

```
asig moogladder ain, kcf, kres[, istor]  
  
asig moogladder ain, acf, kres[, istor]  
  
asig moogladder ain, kcf, ares[, istor]  
  
asig moogladder ain, acf, ares[, istor]
```

## Initialization

*istor* --initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*asig* -- input signal.

*kcf/acf* -- filter cutoff frequency

*kres/ares* -- resonance, generally < 1, but not limited to it. Higher than 1 resonance values might cause aliasing, analogue synths generally allow resonances to be above 1.

## Examples

Here is an example of the moogladder opcode. It uses the file *moogladder.csd* [examples/moogladder.csd].

### Example 526. Example of the moogladder opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# moogvcf

moogvcf — A digital emulation of the Moog diode ladder filter configuration.

## Description

A digital emulation of the Moog diode ladder filter configuration.

## Syntax

```
ares moogvcf asig, xfco, xres [,iscale, iskip]
```

## Initialization

*iscale* (optional, default=1) -- internal scaling factor. Use if *asig* is not in the range +/-1. Input is first divided by *iscale*, then output is multiplied *iscale*. Default value is 1. (New in Csound version 3.50)

*iskip* (optional, default=0) -- if non zero skip the initialisation of the filter. (New in Csound version 4.23f13 and 5.0)

## Performance

*asig* -- input signal

*xfco* -- filter cut-off frequency in Hz. As of version 3.50, may i-,k-, or a-rate.

*xres* -- amount of resonance. Self-oscillation occurs when *xres* is approximately one. As of version 3.50, may a-rate, i-rate, or k-rate.

*moogvcf* is a digital emulation of the Moog diode ladder filter configuration. This emulation is based loosely on the paper “Analyzing the Moog VCF with Considerations for Digital Implementation” by Stilson and Smith (CCRMA). This version was originally coded in Csound by Josep Comajuncosas. Some modifications and conversion to C were done by Hans Mikelson.

### Warning

Before version 6.02 this filter required that the input signal be normalized to one. This can be easily achieved using *0dbfs*, like this:

```
ares moogvcf asig, kfco, kres, 0dbfs
```

You can also use *moogvcf2* which defaults scaling to *0dbfs*.

## Examples

Here is an example of the moogvcf opcode. It uses the file *moogvcf.csd* [examples/moogvcf.csd].

### Example 527. Example of the moogvcf opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# moogvcf2

moogvcf2 — A digital emulation of the Moog diode ladder filter configuration.

## Description

A digital emulation of the Moog diode ladder filter configuration.

## Syntax

```
ares moogvcf2 asig, xfco, xres [,iscale, iskip]
```

## Initialization

*iscale* (optional, default=0dBfs) -- internal scaling factor, as the operation of the code requires the signal to be in the range +/-1. Input is first divided by *iscale*, then output is multiplied by *iscale*.

*iskip* (optional, default=0) -- if non zero skip the initialisation of the filter.

## Performance

*asig* -- input signal

*xfco* -- filter cut-off frequency in Hz. which may be i-,k-, or a-rate.

*xres* -- amount of resonance. Self-oscillation occurs when *xres* is approximately one. May be a-rate, i-rate, or k-rate.

*moogvcf2* is a digital emulation of the Moog diode ladder filter configuration. This emulation is based loosely on the paper “Analyzing the Moog VCF with Considerations for Digital Implementation” by Stilson and Smith (CCRMA). This version was originally coded in Csound by Josep Comajuncosas. Some modifications and conversion to C were done by Hans Mikelson and then adjusted.

*moogvcf2* is identical to *moogvcf*, except that the *iscale* parameter defaults to 0dbfs instead of 0, guaranteeing that amplitude will usually be OK.

## Examples

Here is an example of the *moogvcf2* opcode. It uses the file *moogvcf2.csd* [examples/moogvcf2.csd].

### Example 528. Example of the *moogvcf2* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# moscil

`moscil` — Sends a stream of the MIDI notes.

## Description

Sends a stream of the MIDI notes.

## Syntax

```
moscil kchn, knum, kvel, kdur, kpause
```

## Performance

*kchn* -- MIDI channel number (1-16)

*knum* -- note number (0-127)

*kvel* -- velocity (0-127)

*kdur* -- note duration in seconds

*kpause* -- pause duration after each noteoff and before new note in seconds

*moscil* and *midion* are the most powerful MIDI OUT opcodes. *moscil* (MIDI oscil) plays a stream of notes of *kdur* duration. Channel, pitch, velocity, duration and pause can be controlled at k-rate, allowing very complex algorithmically generated melodic lines. When current instrument is deactivated, the note played by current instance of *moscil* is forcedly truncated.

Any number of *moscil* opcodes can appear in the same Csound instrument, allowing a counterpoint-style polyphony within a single instrument.

## Examples

Here is an example of the *moscil* opcode. It uses the file *moscil.csd* [examples/moscil.csd].

### Example 529. Example of the moscil opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

This example generates a stream of notes for every note received on the MIDI input. It generates MIDI notes on csound's MIDI output, so be sure to connect something.

# mp3in

mp3in — Reads mono or stereo audio data from an external MP3 file.

## Description

Reads mono or stereo audio data from an external MP3 file.

## Syntax

```
ar1, ar2 mp3in ifilcod[, iskptim, iformat, iskipinit, ibufsize]  
ar1 mp3in ifilcod[, iskptim, iformat, iskipinit, ibufsize]
```

## Initialization

*ifilcod* -- integer or character-string denoting the source soundfile name. An integer denotes the file *soundin.filcod* ; a character-string (in double quotes, spaces permitted) gives the filename itself, optionally a full pathname. If not a full path, the named file is sought first in the current directory, then in that given by the environment variable *SSDIR* (if defined) then by *SFDIR*.

*iskptim* (optional) -- time in seconds of input sound to be skipped. The default value is 0.

*iformat* (optional) -- specifies the audio data file format: currently not implemented and always defaults to stereo.

*iskipinit* (optional) -- switches off all initialisation if non zero (default =0).

*ibuffersize* (optional) -- sets the internal buffer size for reading. If the value is omitted, zero or negative it defaults to 4096 bytes.

## Performance

Reads audio data from an external MP3 file.

## Examples

Here is an example of the mp3in opcode. It uses the file *mp3in.csd* [examples/mp3in.csd].

### Example 530. Example of the mp3in opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# mp3len

`mp3len` — Returns the length of an MP3 sound file.

## Description

Returns the length of an MP3 sound file.

## Syntax

```
ir mp3len ifilcod
```

## Initialization

`ifilcod` -- sound file to be queried

## Performance

`mp3len` returns the length of the sound file `ifilcod` in seconds.

## Examples

Here is an example of the `mp3len` opcode. It uses the file `mp3len.csd` [examples/mp3len.csd].

### Example 531. Example of the mp3len opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# mpulse

mpulse — Generates a set of impulses.

## Description

Generates a set of impulses of amplitude *kamp* separated by *kintvl* seconds (or samples if *kintvl* is negative). The first impulse is generated after a delay of *ioffset* seconds.

## Syntax

```
ares mpulse kamp, kintvl [, ioffset]
```

## Initialization

*ioffset* (optional, default=0) -- the delay before the first impulse. If it is negative, the value is taken as the number of samples, otherwise it is in seconds. Default is zero.

## Performance

*kamp* -- amplitude of the impulses generated

*kintvl* -- Interval of time in seconds (or samples if *kintvl* is negative) to the next pulse.

After the initial delay, an impulse of *kamp* amplitude is generated as a single sample. Immediately after generating the impulse, the time of the next one is determined from the value of *kintvl* at that precise moment. This means that any changes in *kintvl* between impulses are discarded. If *kintvl* is zero, there is an infinite wait to the next impulse. If *kintvl* is negative, the interval is counted in number of samples rather than seconds.

## Examples

Here is an example of the mpulse opcode. It uses the file *mpulse.csd* [examples/mpulse.csd].

### Example 532. Example of the mpulse opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## mrtmsg

mrtmsg — Send system real-time messages to the MIDI OUT port.

## Description

Send system real-time messages to the MIDI OUT port.

## Syntax

**mrtmsg** imsgtype

## Initialization

*imsgtype* -- type of real-time message:

- 1 sends a START message (0xFA);
- 2 sends a CONTINUE message (0xFB);
- 0 sends a STOP message (0xFC);
- -1 sends a SYSTEM RESET message (0xFF);
- -2 sends an ACTIVE SENSING message (0xFE)

## Performance

Sends a real-time message once, in init stage of current instrument. *imsgtype* parameter is a flag to indicate the message type.

</CsoundSynthesizer>
```

This results in two delays, one with length of 1.2 and gain of .5, and one with length of 1.4 and gain of .2.

# mute

mute — Mutes/unmutes new instances of a given instrument.

## Description

Mutes/unmutes new instances of a given instrument.

## Syntax

```
mute insnum [, iswitch]
```

```
mute "insname" [, iswitch]
```

## Initialization

*insnum* -- instrument number. Equivalent to *p1* in a score *i statement*.

“*insname*” -- A string (in double-quotes) representing a named instrument.

*iswitch* (optional, default=0) -- represents a switch to mute/unmute an instrument. A value of 0 will mute new instances of an instrument, other values will unmute them. The default value is 0.

## Performance

All new instances of instrument inst will me muted (iswitch = 0) or unmuted (iswitch not equal to 0). There is no difficulty with muting muted instruments or unmuting unmuted instruments. The mechanism is the same as used by the score *q statement*. For example, it is possible to mute in the score and unmute in some instrument.

Muting/Unmuting is indicated by a message (depending on message level).

## Examples

Here is an example of the mute opcode. It uses the file *mute.csd* [examples/mute.csd].

### Example 534. Example of the mute opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## mxadsr

mxadsr — Calculates the classical ADSR envelope using the *expsegr* mechanism.

## Description

Calculates the classical ADSR envelope using the *expsegr* mechanism.

## Syntax

```
ares mxadsr iatt, idec, islev, irel [, idel] [, ireltim]
```

```
kres mxadsr iatt, idec, islev, irel [, idel] [, ireltim]
```

## Initialization

*iatt* -- duration of attack phase

*idec* -- duration of decay

*islev* -- level for sustain phase

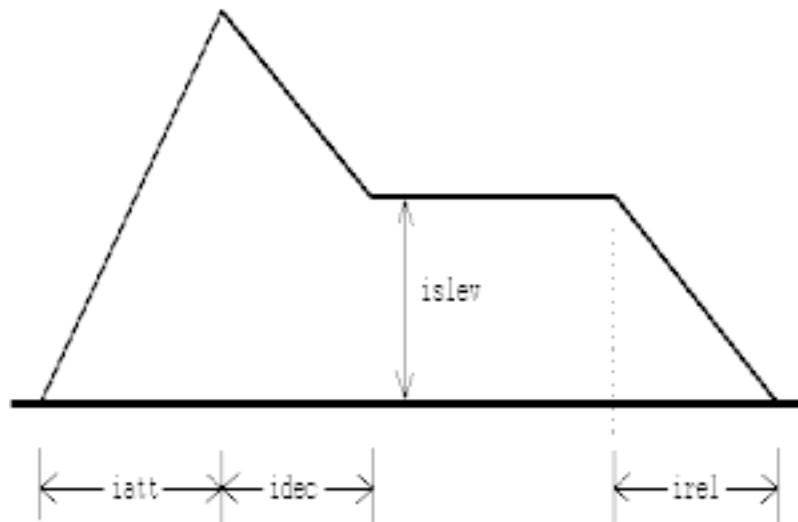

*irel* -- duration of release phase

*idel* (optional, default=0) -- period of zero before the envelope starts

*ireltim* (optional, default=-1) -- Control release time after receiving a MIDI noteoff event. If less than zero, the longest release time given in the current instrument is used. If zero or more, the given value will be used for release time. Its default value is -1. (New in Csound 3.59 - not yet properly tested)

## Performance

The envelope is in the range 0 to 1 and may need to be scaled further. The envelope may be described as:

Picture of an ADSR envelope.

The length of the sustain is calculated from the length of the note. This means *adsr* is not suitable for use with MIDI events. The opcode *madsr* uses the *linsegr* mechanism, and so can be used in MIDI applications. The opcode *mxadsr* is identical to *madsr* except it uses exponential, rather than linear, line segments.

You can use other pre-made envelopes which start a release segment upon receiving a note off message, like *linsegr* and *expsegr*, or you can construct more complex envelopes using *xtratim* and *release*. Note that you don't need to use *xtratim* if you are using *mxadsr*, since the time is extended automatically.

*mxadsr* is new in Csound version 3.51.

## Examples

Here is an example of the *mxadsr* opcode. It uses the file *mxadsr.csd* [examples/mxadsr.csd].

### Example 535. Example of the mxadsr opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

November 2002. Thanks to Rasmus Ekman, added documentation for the *ireltim* parameter.

November 2003. Thanks to Kanata Motohashi, fixed the link to the *linsegr* opcode.

# nchnls

nchnls — Sets the number of channels of audio output.

## Description

These statements are global value *assignments*, made at the beginning of an orchestra, before any instrument block is defined. Their function is to set certain *reserved symbol variables* that are required for performance. Once set, these reserved symbols can be used in expressions anywhere in the orchestra.

## Syntax

```
nchnls = iarg
```

## Initialization

*nchnls* = (optional) -- set number of channels of audio output to *iarg*. (1 = mono, 2 = stereo, 4 = quadraphonic.) The default value is 1 (mono).

In addition, any *global variable* [55] can be initialized by an *init-time assignment* anywhere before the first *instr statement*. All of the above assignments are run as instrument 0 (i-pass only) at the start of real performance.

## Examples

Here is an example of the nchnls opcode. It uses the file *nchnls.csd* [examples/nchnls.csd].

### Example 536. Example of the nchnls opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## nchnls\_i

nchnls\_i — Sets the number of channels of audio input.

## Description

These statements are global value *assignments*, made at the beginning of an orchestra, before any instrument block is defined. Their function is to set certain *reserved symbol variables* that are required for performance. Once set, these reserved symbols can be used in expressions anywhere in the orchestra.

## Syntax

```
nchnls_i = iarg
```

## Initialization

*nchnls\_i* = (optional) -- set number of channels of audio input to *iarg*. (1 = mono, 2 = stereo, 4 = quadraphonic.) The default value is the value of *nchnls*.

In addition, any *global variable* [55] can be initialized by an *init-time assignment* anywhere before the first *instr statement*. All of the above assignments are run as instrument 0 (i-pass only) at the start of real performance.

## Examples

Here is an example of the nchnls\_i opcode. It uses the file *nchnls\_i.csd* [examples/nchnls\_i.csd].

### Example 537. Example of the nchnls\_i opcode.

# nestedap

nestedap — Three different nested all-pass filters.

## Description

Three different nested all-pass filters, useful for implementing reverbs.

## Syntax

```
ares nestedap asig, imode, imaxdel, idel1, igain1 [, idel2] [, igain2] \
[, idel3] [, igain3] [, istor]
```

## Initialization

*imode* -- operating mode of the filter:

- 1 = simple all-pass filter
- 2 = single nested all-pass filter
- 3 = double nested all-pass filter

*idel1*, *idel2*, *idel3* -- delay times of the filter stages. Delay times are in seconds and must be greater than zero. *idel1* must be greater than the sum of *idel2* and *idel3*.

*igain1*, *igain2*, *igain3* -- gain of the filter stages.

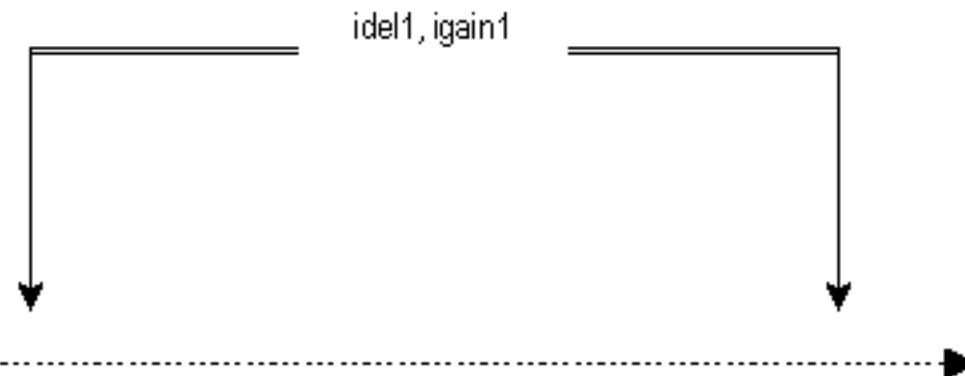

*imaxdel* -- will be necessary if k-rate delays are implemented. Not currently used.

*istor* -- Skip initialization if non-zero (default: 0).

## Performance

*asig* -- input signal

If *imode* = 1, the filter takes the form:

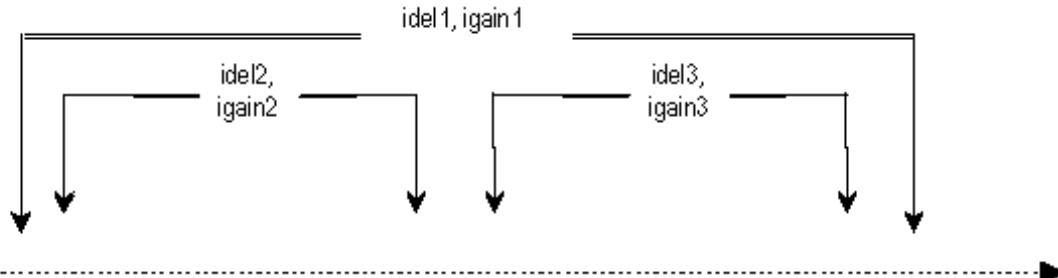

Picture of imode 1 filter.

If *imode* = 2, the filter takes the form:

Picture of imode 2 filter.

If *imode* = 3, the filter takes the form:

Picture of imode 3 filter.

## Examples

Here is an example of the nestedap opcode. It uses the file *nestedap.csd* [examples/nestedap.csd], and *beats.wav* [examples/beats.wav].

# nlfilt

nlfilt — A filter with a non-linear effect.

## Description

Implements the filter:

$$Y\{n\} = a Y\{n-1\} + b Y\{n-2\} + d Y^2\{n-L\} + X\{n\} - C$$

described in Dobson and Fitch (ICMC'96)

## Syntax

```
ares nlfilt ain, ka, kb, kd, kC, kL
```

## Performance

1. Non-linear effect. The range of parameters are:

a = b = 0  
d = 0.8, 0.9, 0.7  
C = 0.4, 0.5, 0.6  
L = 20

This affects the lower register most but there are audible effects over the whole range. We suggest that it may be useful for coloring drums, and for adding arbitrary highlights to notes.

2. Low Pass with non-linear. The range of parameters are:

a = 0.4  
b = 0.2  
d = 0.7  
C = 0.11  
L = 20, ... 200

There are instability problems with this variant but the effect is more pronounced of the lower register, but is otherwise much like the pure comb. Short values of L can add attack to a sound.

3. High Pass with non-linear. The range of parameters are:

a = 0.35  
b = -0.3  
d = 0.95  
C = 0.2, ... 0.4

L = 200

4. High Pass with non-linear. The range of parameters are:

a = 0.7  
b = -0.2, ... 0.5  
d = 0.9  
C = 0.12, ... 0.24  
L = 500, 10

The high pass version is less likely to oscillate. It adds scintillation to medium-high registers. With a large delay  $L$  it is a little like a reverberation, while with small values there appear to be formant-like regions. There are arbitrary color changes and resonances as the pitch changes. Works well with individual notes.

## Warning

The "useful" ranges of parameters are not yet mapped.

## Examples

Here is an example of the `nlfilt` opcode. It uses the file `nlfilt.csd` [examples/nlfilt.csd].

### Example 539. Example of the `nlfilt` opcode.

## nlfilt2

nlfilt2 — A filter with a non-linear effect and blowup protection.

### Description

Implements the filter:

$$Y\{n\} = \tanh(a Y\{n-1\} + b Y\{n-2\} + d Y^2\{n-L\} + X\{n\} - C)$$

described in Dobson and Fitch (ICMC'96) as modified by Risto Holopainen.

### Syntax

```
ares nlfilt2 ain, ka, kb, kd, kC, kL
```

### Performance

1. Non-linear effect. The range of parameters are:

a = b = 0  
d = 0.8, 0.9, 0.7  
C = 0.4, 0.5, 0.6  
L = 20

This affects the lower register most but there are audible effects over the whole range. We suggest that it may be useful for coloring drums, and for adding arbitrary highlights to notes.

2. Low Pass with non-linear. The range of parameters are:

a = 0.4  
b = 0.2  
d = 0.7  
C = 0.11  
L = 20, ... 200

There are instability problems with this variant but the effect is more pronounced of the lower register, but is otherwise much like the pure comb. Short values of L can add attack to a sound.

3. High Pass with non-linear. The range of parameters are:

a = 0.35  
b = -0.3  
d = 0.95  
C = 0.2, ... 0.4

L = 200

4. High Pass with non-linear. The range of parameters are:

a = 0.7  
b = -0.2, ... 0.5  
d = 0.9  
C = 0.12, ... 0.24  
L = 500, 10

The high pass version is less likely to oscillate. It adds scintillation to medium-high registers. With a large delay  $L$  it is a little like a reverberation, while with small values there appear to be formant-like regions. There are arbitrary color changes and resonances as the pitch changes. Works well with individual notes.

## Warning

# noise

`noise` — A white noise generator with an IIR lowpass filter.

## Description

A white noise generator with an IIR lowpass filter.

## Syntax

```
ares noise xamp, kbeta
```

## Performance

*xamp* -- amplitude of final output

*kbeta* -- beta of the lowpass filter. Should be in the range of -1 to 1, exclusive of the end-points.

The filter equation is:

$$y_n = \sqrt{(1 - \beta^2)} * x_n + \beta y_{(n-1)}$$

where  $x_n$  is the original white noise and  $y_n$  is lowpass filtered noise. The higher # is, the lower the filter's cut-off frequency. The cutoff frequency is roughly  $sr * ((1-kbeta)/2)$ .

## Examples

Here is an example of the noise opcode. It uses the file *noise.csd* [examples/noise.csd].

### Example 541. Example of the noise opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# noteoff

`noteoff` — Send a noteoff message to the MIDI OUT port.

## Description

Send a noteoff message to the MIDI OUT port.

## Syntax

```
noteoff ichn, inum, ivel
```

## Initialization

*ichn* -- MIDI channel number (1-16)

*inum* -- note number (0-127)

*ivel* -- velocity (0-127)

## Performance

*noteon* (i-rate note on) and *noteoff* (i-rate note off) are the simplest MIDI OUT opcodes. *noteon* sends a MIDI noteon message to MIDI OUT port, and *noteoff* sends a noteoff message. A *noteon* opcode must always be followed by an *noteoff* with the same channel and number inside the same instrument, otherwise the note will play endlessly.

These *noteon* and *noteoff* opcodes are useful only when introducing a *timeout* statement to play a non-zero duration MIDI note. For most purposes, it is better to use *noteondur* and *noteondur2*.

# noteon

`noteon` — Send a noteon message to the MIDI OUT port.

## Description

Send a noteon message to the MIDI OUT port.

## Syntax

```
noteon ichn, inum, ivel
```

## Initialization

*ichn* -- MIDI channel number (1-16)

*inum* -- note number (0-127)

*ivel* -- velocity (0-127)

## Performance

*noteon* (i-rate note on) and *noteoff* (i-rate note off) are the simplest MIDI OUT opcodes. *noteon* sends a MIDI noteon message to MIDI OUT port, and *noteoff* sends a noteoff message. A *noteon* opcode must always be followed by an *noteoff* with the same channel and number inside the same instrument, otherwise the note will play endlessly.

These *noteon* and *noteoff* opcodes are useful only when introducing a *timeout* statement to play a non-zero duration MIDI note. For most purposes, it is better to use *noteondur* and *noteondur2*.

# noteondur2

`noteondur2` — Sends a noteon and a noteoff MIDI message both with the same channel, number and velocity.

## Description

Sends a noteon and a noteoff MIDI message both with the same channel, number and velocity.

## Syntax

```
noteondur2 ichn, inum, ivel, idur
```

## Initialization

*ichn* -- MIDI channel number (1-16)

*inum* -- note number (0-127)

*ivel* -- velocity (0-127)

*idur* -- how long, in seconds, this note should last.

## Performance

`noteondur2` (i-rate note on with duration) sends a noteon and a noteoff MIDI message both with the same channel, number and velocity. Noteoff message is sent after *idur* seconds are elapsed by the time `noteondur2` was active.

`noteondur` differs from `noteondur2` in that `noteondur` truncates note duration when current instrument is deactivated by score or by real-time playing, while `noteondur2` will extend performance time of current instrument until *idur* seconds have elapsed. In real-time playing, it is suggested to use `noteondur` also for undefined durations, giving a large *idur* value.

Any number of `noteondur2` opcodes can appear in the same Csound instrument, allowing chords to be played by a single instrument.

## Examples

Here is an example of the `noteondur2` opcode. It uses the file `noteondur2.csd` [examples/noteondur2.csd].

### Example 543. Example of the `noteondur2` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

This example generates notes for every note received on the MIDI input. It generates MIDI notes on csound's MIDI output, so be sure to connect something.

# nreverb

*nreverb* — A reverberator consisting of 6 parallel comb-lowpass filters.

## Description

This is a reverberator consisting of 6 parallel comb-lowpass filters being fed into a series of 5 allpass filters. *nreverb* replaces *reverb2* (version 3.48) and so both opcodes are identical.

## Syntax

```
ares nreverb asig, ktime, khdif [, iskip] [,inumCombs] [, ifnCombs] \
[, inumAlpas] [, ifnAlpas]
```

## Initialization

*iskip* (optional, default=0) -- Skip initialization if present and non-zero.

*inumCombs* (optional) -- number of filter constants in comb filter. If omitted, the values default to the *nreverb* constants. New in Csound version 4.09.

*ifnCombs* - function table with *inumCombs* comb filter time values, followed by the same number of gain values. The ftable should not be rescaled (use negative fgen number). Positive time values are in seconds. The time values are converted internally into number of samples, then set to the next greater prime number. If the time is negative, it is interpreted directly as time in sample frames, and no processing is done (except negation). New in Csound version 4.09.

*inumAlpas*, *ifnAlpas* (optional) -- same as *inumCombs/ifnCombs*, for allpass filter. New in Csound 4.09.

## Performance

The input signal *asig* is reverberated for *ktime* seconds. The parameter *khdif* controls the high frequency diffusion amount. The values of *khdif* should be from 0 to 1. If *khdif* is set to 0, all the frequencies decay with the same speed. If *khdif* is 1, high frequencies decay faster than lower ones. If *ktime* is inadvertently set to a non-positive number, *ktime* will be reset automatically to 0.01. (New in Csound version 4.07.)

As of Csound version 4.09, *nreverb* may read any number of comb and allpass filter from an ftable.

## Examples

Here is a simple example of the *nreverb* opcode. It uses the file *nreverb.csd* [examples/nreverb.csd].

### Example 546. Simple example of the nreverb opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# nrpn

**nrpn** — Sends a Non-Registered Parameter Number to the MIDI OUT port.

## Description

Sends a NPN (Non-Registered Parameter Number) message to the MIDI OUT port each time one of the input arguments changes.

## Syntax

```
nrpn kchan, kparmnum, kparmvalue
```

## Performance

*kchan* -- MIDI channel (1-16)

*kparmnum* -- number of NRPN parameter

*kparmvalue* -- value of NRPN parameter

This opcode sends new message when the MIDI translated value of one of the input arguments changes. It operates at k-rate. Useful with the MIDI instruments that recognize NRPNs (for example with the newest sound-cards with internal MIDI synthesizer such as SB AWE32, AWE64, GUS etc. in which each patch parameter can be changed during the performance via NRPN)

## Examples

Here is an example of the nrpn opcode. It uses the file *nrpn.csd* [examples/nrpn.csd].

### Example 548. Example of the nrpn opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

This example generates notes for every note received on the MIDI input. It generates MIDI notes on csound's MIDI output, so be sure to connect something.

```

New in Csound version 3.492

Thanks goes to Rasmus Ekman for pointing out the correct MIDI channel and controller number ranges.

# nsamp

`nsamp` — Returns the number of samples loaded into a stored function table number.

## Description

Returns the number of samples loaded into a stored function table number.

## Syntax

```
nsamp(x) (init-rate args only)
```

## Performance

Returns the number of samples loaded into stored function table number *x* by GEN01. This is useful when a sample is shorter than the power-of-two function table that holds it. New in Csound version 3.49.

As of Csound version 5.02, *nsamp* works with deferred-length function tables (see *GEN01*).

*nsamp* differs from *flen* in that *nsamp* gives the number of sample frames loaded, while *flen* gives the total number of samples. For example, with a stereo sound file of 10000 samples, *flen()* would return 19999 (i.e. a total of 20000 mono samples, not including a guard point), but *nsamp()* returns 10000.

## Examples

Here is an example of the *nsamp* opcode. It uses the file *nsamp.csd* [examples/nsamp.cs], *kickroll.wav* [examples/kickroll.wav]. and *fox.wav* [examples/fox.wav].

### Example 549. Example of the nsamp opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac    ;;;realtime audio out
;-iadc   ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime output leave only the line below:
; -o nsamp.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>
; slightly adapted example from Jonathan Murphy Dec 2006

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1

ifn = p4 ; table number
ilen = nsamp(ifn)
prints "actual numbers of samples = %d\n", ilen
itrns = 1 ; no transposition
ilps = 0 ; loop starts at index 0
ilpe = ilen ; ends at value returned by nsamp above
```

```
imode = 1 ; loops forward
istrt = 0 ; commence playback at index 0 samples
; lphasor provides index into f1
alpchs lphasor itrns, ilps, ilpe, imode, istrt
atab tablei alpchs, ifn
outs atab, atab

endin
</CsInstruments>
<CsScore>
f 1 0 262144 1 "kickroll.wav" 0 4 1 ;stereo file in table, with lots of zeroes
f 2 0 262144 1 "fox.wav" 0 4 1 ;mono file in table, with lots of zeroes

i1 0 10 1
i1 + 10 2
e

</CsScore>
</CsoundSynthesizer>
```

Since the stereo audio file “kickroll.wav” has 37792 samples and the mono file “fox.wav” has 121569 samples, its output should include lines like these:

```
actual numbers of samples = 37792
actual numbers of samples = 121569
```

# nstance

nstance — Schedules a new instrument instance, storing the instance handle in a variable.

## Description

Schedules a new instrument nstance, returning a handle that can be used later to refer directly to the running nstance. This opcode is similar to schedule, but has the added facility of retrieving the nstance handle.

## Syntax

```
iHandle nstance insnum, iwhen, idur [, ip4] [, ip5] [...]  
  
iHandle nstance "insname", iwhen, idur [, ip4] [, ip5] [...]
```

## Initialization

*iHandle* -- this variable will contain a handle to the event instance. It can be used, for example, to stop the given instrument instance via the turnoff opcode. Note that the instance handle is only valid once the instrument is initialised.

*insnum* -- instrument number. Equivalent to p1 in a score *i statement*. *insnum* must be a number greater than the number of the calling instrument.

“*insname*” -- A string (in double-quotes) representing a named instrument.

*iwhen* -- start time of the new event. Equivalent to p2 in a score *i statement*. *iwhen* must be nonnegative. If *iwhen* is zero, *insnum* must be greater than or equal to the p1 of the current instrument.

*idur* -- duration of event. Equivalent to p3 in a score *i statement*.

*ip4, ip5, ...* -- Equivalent to p4, p5, etc., in a score *i statement*.

## Performance

*nstance* adds a new score event. The arguments, including options, are the same as in a score. The *iwhen* time (p2) is measured from the time of this event.

If the duration is zero or negative the new event is of MIDI type, and inherits the release sub-event from the scheduling instruction.

### Note

Note that the *nstance* opcode can't accept string p-fields. If you need to pass strings when instantiating an instrument, use the *scoreline* or *scoreline\_i* opcode.

## Examples

Here is an example of the nstance opcode. It uses the file *nstance.csd* [examples/nstance.csd].

**Example 550. Example of the nstance opcode.**

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## nstrnum

nstrnum — Returns the number of a named instrument.

### Description

Returns the number of a named instrument.

### Syntax

```
insno nstrnum "name"
```

### Initialization

*insno* -- the instrument number of the named instrument.

### Performance

"*name*" -- the named instrument's name.

If an instrument with the specified name does not exist, an init error occurs, and -1 is returned.

### Credits

Author: Istvan Varga  
New in version 4.23  
Written in the year 2002.

# ntrpol

ntrpol — Calculates the weighted mean value of two input signals.

## Description

Calculates the weighted mean value (i.e. linear interpolation) of two input signals

## Syntax

```
ares ntrpol asig1, asig2, kpoint [, imin] [, imax]  
  
ires ntrpol isig1, isig2, ipoint [, imin] [, imax]  
  
kres ntrpol ksig1, ksig2, kpoint [, imin] [, imax]
```

## Initialization

*imin* -- minimum xpoint value (optional, default 0)

*imax* -- maximum xpoint value (optional, default 1)

## Performance

*xsig1*, *xsig2* -- input signals

*xpoint* -- interpolation point between the two values

*ntrpol* opcode outputs the linear interpolation between two input values. *xpoint* is the distance of evaluation point from the first value. With the default values of *imin* and *imax*, (0 and 1) a zero value indicates no distance from the first value and the maximum distance from the second one. With a 0.5 value, *ntrpol* will output the mean value of the two inputs, indicating the exact half point between *xsig1* and *xsig2*. A 1 value indicates the maximum distance from the first value and no distance from the second one. The range of *xpoint* can be also defined with *imin* and *imax* to make its management easier.

These opcodes are useful for crossfading two signals.

## Examples

Here is an example of the *ntrpol* opcode. It uses the file *ntrpol.csd* [examples/ntrpol.csd].

### Example 551. Example of the ntrpol opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# octave

octave — Calculates a factor to raise/lower a frequency by a given amount of octaves.

## Description

Calculates a factor to raise/lower a frequency by a given amount of octaves.

## Syntax

```
octave(x)
```

This function works at a-rate, i-rate, and k-rate.

## Initialization

*x* -- a value expressed in octaves.

## Performance

The value returned by the *octave* function is a factor. You can multiply a frequency by this factor to raise/lower it by the given amount of octaves.

## Examples

Here is an example of the octave opcode. It uses the file *octave.csd* [examples/octave.csd].

### Example 552. Example of the octave opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac      ;;;realtime audio out
;-iadc     ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime ouput leave only the line below:
; -o octave.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1

iroot = 440          ; root note is A above middle-C (440 Hz)
koct = lfo 5, 1, 5 ; generate sawtooth, go from 5 octaves higher to root
koc = int(koct)       ; produce only whole numbers
kfactor = octave(koc) ; for octave
knew = iroot * kfactor
printk2 knew

asig pluck 1, knew, 1000, 0, 1
```

```
asig dcblock asig ;remove DC
      outs asig, asig

endin
</CsInstruments>
<CsScore>

i 1 0 5
e

</CsScore>
</CsoundSynthesizer>
```

Its output should include lines like:

```
il  3520.00000
il  1760.00000
il  880.00000
il  440.00000
il  7040.00000
il  3520.00000
il  1760.00000
il  880.00000
il  440.00000
.......
```

# octcps

`octcps` — Converts a cycles-per-second value to octave-point-decimal.

## Description

Converts a cycles-per-second value to octave-point-decimal.

## Syntax

`octcps (cps) (init- or control-rate args only)`

where the argument within the parentheses may be a further expression.

## Performance

`octcps` and its related opcodes are really *value converters* with a special function of manipulating pitch data.

Data concerning pitch and frequency can exist in any of the following forms:

**Table 16. Pitch and Frequency Values**

| Name                              | Abbreviation |
|-----------------------------------|--------------|
| octave point pitch-class (8ve.pc) | pch          |
| octave point decimal              | oct          |
| cycles per second                 | cps          |
| Midi note number (0-127)          | midinn       |

The first two forms consist of a whole number, representing octave registration, followed by a specially interpreted fractional part. For *pch*, the fraction is read as two decimal digits representing the 12 equal-tempered pitch classes from .00 for C to .11 for B. For *oct*, the fraction is interpreted as a true decimal fractional part of an octave. The two fractional forms are thus related by the factor 100/12. In both forms, the fraction is preceded by a whole number octave index such that 8.00 represents Middle C, 9.00 the C above, etc. Midi note number values range between 0 and 127 (inclusively) with 60 representing Middle C, and are usually whole numbers. Thus A440 can be represented alternatively by 440 (*cps*), 69 (*midinn*), 8.09 (*pch*), or 8.75 (*oct*). Microtonal divisions of the *pch* semitone can be encoded by using more than two decimal places.

The mnemonics of the pitch conversion units are derived from morphemes of the forms involved, the second morpheme describing the source and the first morpheme the object (result). Thus *cpspch*(8.09) will convert the pitch argument 8.09 to its *cps* (or Hertz) equivalent, giving the value of 440. Since the argument is constant over the duration of the note, this conversion will take place at i-time, before any samples for the current note are produced.

By contrast, the conversion *cpsoct*(8.75 + *k1*) which gives the value of A440 transposed by the octave interval *k1*. The calculation will be repeated every k-period since that is the rate at which *k1* varies.

## Note

The conversion from *pch*, *oct*, or *midinn* into *cps* is not a linear operation but involves an exponential process that could be time-consuming when executed repeatedly. Csound now uses a built-in table lookup to do this efficiently, even at audio rates. Because the table index is truncated without interpolation, pitch resolution when using one of these opcodes is limited to 8192 discrete and equal divisions of the octave, and some pitches of the standard 12-tone equally-tempered scale are very slightly mistuned (by at most 0.15 cents).

## Examples

Here is an example of the *octcps* opcode. It uses the file *octcps.csd* [examples/octcps.csd].

### Example 553. Example of the *octcps* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out   Audio in

# octmidi

octmidi — Get the note number, in octave-point-decimal units, of the current MIDI event.

## Description

Get the note number, in octave-point-decimal units, of the current MIDI event.

## Syntax

```
ioct octmidi
```

## Performance

Get the note number of the current MIDI event, expressed in octave-point-decimal units, for local processing.

### octmidi vs. octmidinn

The *octmidi* opcode only produces meaningful results in a Midi-activated note (either real-time or from a Midi score with the -F flag). With *octmidi*, the Midi note number value is taken from the Midi event that is internally associated with the instrument instance. On the other hand, the *octmidinn* opcode may be used in any Csound instrument instance whether it is activated from a Midi event, score event, line event, or from another instrument. The input value for *octmidinn* might for example come from a p-field in a textual score or it may have been retrieved from the real-time Midi event that activated the current note using the *notnum* opcode.

## Examples

Here is an example of the *octmidi* opcode. It uses the file *octmidi.csd* [examples/octmidi.csd].

### Example 554. Example of the octmidi opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# octmidib

octmidib — Get the note number of the current MIDI event and modify it by the current pitch-bend value, express it in octave-point-decimal.

## Description

Get the note number of the current MIDI event and modify it by the current pitch-bend value, express it in octave-point-decimal.

## Syntax

```
ioc Octmidib [irange]
```

```
kOct Octmidib [irange]
```

## Initialization

*irange* (optional) -- the pitch bend range in semitones

## Performance

Get the note number of the current MIDI event, modify it by the current pitch-bend value, and express the result in octave-point-decimal units. Available as an i-time value or as a continuous k-rate value.

## Examples

Here is an example of the octmidib opcode. It uses the file *octmidib.csd* [examples/octmidib.csd].

### Example 555. Example of the octmidib opcode.

# octmidinn

octmidinn — Converts a Midi note number value to octave-point-decimal.

## Description

Converts a Midi note number value to octave-point-decimal.

## Syntax

```
octmidinn (MidiNoteNumber)  (init- or control-rate args only)
```

where the argument within the parentheses may be a further expression.

## Performance

*octmidinn* is a function that takes an i-rate or k-rate value representing a Midi note number and returns the equivalent pitch value in Csound's octave-point-decimal format. This conversion assumes that Middle C (8.000 in *oct*) is Midi note number 60. Midi note number values are typically integers in the range from 0 to 127 but fractional values or values outside of this range will be interpreted consistently.

### octmidinn vs. octmidi

The *octmidinn* opcode may be used in any Csound instrument instance whether it is activated from a Midi event, score event, line event, or from another instrument. The input value for *octmidinn* might for example come from a p-field in a textual score or it may have been retrieved from the real-time Midi event that activated the current note using the *notnum* opcode. You must specify an i-rate or k-rate expression for the Midi note number that is to be converted. On the other hand, the *octmidi* opcode only produces meaningful results in a Midi-activated note (either real-time or from a Midi score with the -F flag). With *octmidi*, the Midi note number value is taken from the Midi event associated with the instrument instance, and no location or expression for this value may be specified.

*octmidinn* and its related opcodes are really *value converters* with a special function of manipulating pitch data.

Data concerning pitch and frequency can exist in any of the following forms:

**Table 17. Pitch and Frequency Values**

| Name                              | Abbreviation |
|-----------------------------------|--------------|
| octave point pitch-class (8ve.pc) | pch          |
| octave point decimal              | oct          |
| cycles per second                 | cps          |
| Midi note number (0-127)          | midinn       |

The first two forms consist of a whole number, representing octave registration, followed by a specially interpreted fractional part. For *pch*, the fraction is read as two decimal digits representing the 12 equal-

tempered pitch classes from .00 for C to .11 for B. For *oct*, the fraction is interpreted as a true decimal fractional part of an octave. The two fractional forms are thus related by the factor 100/12. In both forms, the fraction is preceded by a whole number octave index such that 8.00 represents Middle C, 9.00 the C above, etc. Midi note number values range between 0 and 127 (inclusively) with 60 representing Middle C, and are usually whole numbers. Thus A440 can be represented alternatively by 440 (*cps*), 69 (*midinn*), 8.09 (*pch*), or 8.75 (*oct*). Microtonal divisions of the *pch* semitone can be encoded by using more than two decimal places.

The mnemonics of the pitch conversion units are derived from morphemes of the forms involved, the second morpheme describing the source and the first morpheme the object (result). Thus *cpspch*(8.09) will convert the pitch argument 8.09 to its *cps* (or Hertz) equivalent, giving the value of 440. Since the argument is constant over the duration of the note, this conversion will take place at i-time, before any samples for the current note are produced.

By contrast, the conversion *cpsoct*(8.75 + *k1*) which gives the value of A440 transposed by the octave interval *k1*. The calculation will be repeated every *k*-period since that is the rate at which *k1* varies.

## Note

The conversion from *pch*, *oct*, or *midinn* into *cps* is not a linear operation but involves an exponential process that could be time-consuming when executed repeatedly. Csound now uses a built-in table lookup to do this efficiently, even at audio rates. Because the table index is truncated without interpolation, pitch resolution when using one of these opcodes is limited to 8192 discrete and equal divisions of the octave, and some pitches of the standard 12-tone equally-tempered scale are very slightly mistuned (by at most 0.15 cents).

# Examples

# octpch

`octpch` — Converts a pitch-class value to octave-point-decimal.

## Description

Converts a pitch-class value to octave-point-decimal.

## Syntax

`octpch (pch) (init- or control-rate args only)`

where the argument within the parentheses may be a further expression.

## Performance

`octpch` and its related opcodes are really *value converters* with a special function of manipulating pitch data.

Data concerning pitch and frequency can exist in any of the following forms:

**Table 18. Pitch and Frequency Values**

| Name                              | Abbreviation |
|-----------------------------------|--------------|
| octave point pitch-class (8ve.pc) | pch          |
| octave point decimal              | oct          |
| cycles per second                 | cps          |
| Midi note number (0-127)          | midinn       |

The first two forms consist of a whole number, representing octave registration, followed by a specially interpreted fractional part. For *pch*, the fraction is read as two decimal digits representing the 12 equal-tempered pitch classes from .00 for C to .11 for B. For *oct*, the fraction is interpreted as a true decimal fractional part of an octave. The two fractional forms are thus related by the factor 100/12. In both forms, the fraction is preceded by a whole number octave index such that 8.00 represents Middle C, 9.00 the C above, etc. Midi note number values range between 0 and 127 (inclusively) with 60 representing Middle C, and are usually whole numbers. Thus A440 can be represented alternatively by 440 (*cps*), 69 (*midinn*), 8.09 (*pch*), or 8.75 (*oct*). Microtonal divisions of the *pch* semitone can be encoded by using more than two decimal places.

The mnemonics of the pitch conversion units are derived from morphemes of the forms involved, the second morpheme describing the source and the first morpheme the object (result). Thus *cpspch*(8.09) will convert the pitch argument 8.09 to its *cps* (or Hertz) equivalent, giving the value of 440. Since the argument is constant over the duration of the note, this conversion will take place at i-time, before any samples for the current note are produced.

By contrast, the conversion *cpsoct*(8.75 + *k1*) which gives the value of A440 transposed by the octave interval *k1*. The calculation will be repeated every k-period since that is the rate at which *k1* varies.

## Note

The conversion from *pch*, *oct*, or *midinn* into *cps* is not a linear operation but involves an exponential process that could be time-consuming when executed repeatedly. Csound now uses a built-in table lookup to do this efficiently, even at audio rates. Because the table index is truncated without interpolation, pitch resolution when using one of these opcodes is limited to 8192 discrete and equal divisions of the octave, and some pitches of the standard 12-tone equally-tempered scale are very slightly mistuned (by at most 0.15 cents).

## Examples

Here is an example of the *octpch* opcode. It uses the file *octpch.csd* [examples/octpch.csd].

# olabuffer

olabuffer — Sum overlapping frames of audio as k-rate arrays and read as an audio signal

## Description

*olabuffer* This opcode takes 1 dimensional k-rate arrays that contain sequential frames of audio and sums them based on an overlap factor resulting in an audio signal output. This is useful for frame based audio processing such as spectral analysis/synthesis.

## Syntax

```
aout olabuffer kin, ioverlap
```

## Initialization

*overlap* -- The amount of overlaps per k-array input frame sample size. For example for an input window size of 1024, and a hop size of 256 the overlap factor would be 4. The overlap factor must be larger than or equal to *ksmps* and must also be an integer multiple of the input k-rate array sample count.

## Performance

*aout* -- The resulting audio signal from the added input frames. *kin* -- A k-rate array containing sequential frames of audio.

## Examples

Here is a simple example of the olabuffer opcode. It uses the file *framebuffer.csd* [examples/framebuffer.csd].

### Example 558. Example of the olabuffer opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# opcode

`opcode` — Defines the start of user-defined opcode block.

## Defining opcodes

The `opcode` and `endop` statements allow defining a new opcode that can be used the same way as any of the built-in Csound opcodes. These opcode blocks are very similar to instruments (and are, in fact, implemented as special instruments), but cannot be called as a normal instrument e.g. with the *i statements*.

A user-defined opcode block must precede the instrument (or other opcode) from which it is used. But it is possible to call the opcode from itself. This allows recursion of any depth that is limited only by available memory. Additionally, there is an experimental feature that allows running the opcode definition at a higher control rate than the `kr` value specified in the orchestra header.

Similarly to instruments, the variables and labels of a user-defined opcode block are local and cannot be accessed from the caller instrument (and the opcode cannot access variables of the caller, either).

Some parameters are automatically copied at initialization, however:

- all p-fields (including `p1`)
- extra time (see also `xtratim`, `linsegr`, and related opcodes). This may affect the operation of `linsegr/expsegr/linenr/envlpxr` in the user-defined opcode block.
- MIDI parameters, if there are any.

Also, the release flag (see the `release` opcode) is copied at performance time.

Modifying the note duration in the opcode definition by assigning to `p3`, or using `ihold`, `turnoff`, `xtratim`, `linsegr`, or similar opcodes will also affect the caller instrument. Changes to MIDI controllers (for example with `ctrlinit`) will also apply to the instrument from which the opcode was called.

Use the `setksmps` opcode to set the local `ksmps` value.

The `xin` and `xout` opcodes copy variables to and from the opcode definition, allowing communication with the calling instrument.

The types of input and output variables are defined by the parameters `intypes` and `outtypes`.

### Tip

You can create UDOs which take no inputs or outputs by using 0 instead of a string.

### Notes

- `xin` and `xout` should be called only once, and `xin` should precede `xout`, otherwise an init error and deactivation of the current instrument may occur.
- These opcodes actually run only at i-time. Performance time copying is done by the user

opcode call. This means that skipping *xin* or *xout* with *kgoto* has no effect, while skipping with *igoto* affects both init and performance time operation.

## Syntax

```
opcode name, outtypes, intypes
```

## Initialization

*name* -- name of the opcode. It may consist of any combination of letters, digits, and underscore but should not begin with a digit. If an opcode with the specified name already exists, it is redefined (a warning is printed in such cases). Some reserved words (like *instr* and *endin*) cannot be redefined.

*intypes* -- list of input types, any combination of the characters: a, k, O, P, V, K, i, o, p, and j. A single 0 character can be used if there are no input arguments. Double quotes and delimiter characters (e.g. comma) are *not* needed.

The meaning of the various *intypes* is shown in the following table:

| Type | Description                               | Variable Types Al-lowed | Updated At        |
|------|---|-------------------------|-------------------|
| a    | a-rate variable                           | a-rate                  | a-rate            |
| i    | i-rate variable                           | i-rate                  | i-time            |
| j    | optional i-time, defaults to -1           | i-rate, constant        | i-time            |
| k    | k-rate variable                           | k- and i-rate, constant | k-rate            |
| O    | optional k-rate variable, defaults to 0   | k- and i-rate, constant | k-rate            |
| P    | optional k-rate variable, defaults to 1   | k- and i-rate, constant | k-rate            |
| V    | optional k-rate variable, defaults to 0.5 | k- and i-rate, constant | k-rate            |
| K    | k-rate with initialization                | k- and i-rate, constant | i-time and k-rate |
| o    | optional i-time, defaults to 0            | i-rate, constant        | i-time            |
| p    | optional i-time, defaults to 1            | i-rate, constant        | i-time            |
| S    | string variable                           | i-rate string           | i-time            |

The maximum allowed number of input arguments is 256.

*outtypes* -- list of output types. The format is the same as in the case of *intypes*.

Here are the available *outtypes*:

| Type | Description     | Variable Types Al-lowed | Updated At |
|------|-----------------|-------------------------|------------|
| a    | a-rate variable | a-rate                  | a-rate     |

| Type | Description                | Variable<br>Types<br>allowed | AI-<br>Types      | Updated At |
|------|----------------------------|------------------------------|-------------------|------------|
| i    | i-rate variable            | i-rate                       | i-time            |            |
| k    | k-rate variable            | k-rate                       | k-rate            |            |
| K    | k-rate with initialization | k-rate                       | i-time and k-rate |            |

The maximum allowed number of output arguments is 256.

*iksmps* (optional, default=0) -- sets the local *ksmps* value. Must be a positive integer, and also the *ksmps* of the calling instrument or opcode must be an integer multiple of this value. For example, if *ksmps* is 10 in the instrument from which the opcode was called, the allowed values for *iksmps* are 1, 2, 5, and 10.

If *iksmps* is set to zero, the *ksmps* of the caller instrument or opcode is used (this is the default behavior).

### Note

The local *ksmps* is implemented by splitting up a control period into smaller sub-kperiods and temporarily modifying internal Csound global variables. This also requires converting the rate of k-rate input and output arguments (input variables receive the same value in all sub-kperiods, while outputs are written only in the last one).

### Warning about local *ksmps*

When the local *ksmps* is not the same as the orchestra level *ksmps* value (as specified in the orchestra header), global a-rate operations must not be used in the user-defined opcode block.

These include:

- any access to “ga” variables
- a-rate zak opcodes (*zar*, *zaw*, etc.)
- *tablera* and *tablewa* (these two opcodes may in fact work, but caution is needed)
- The *in* and *out* opcode family (these read from, and write to global a-rate buffers)

In general, the local *ksmps* should be used with care as it is an experimental feature, although it works correctly in most cases.

The *setksmps* statement can be used to set the local *ksmps* value of the user-defined opcode block. It has one i-time parameter specifying the new *ksmps* value (which is left unchanged if zero is used, see also the notes about *iksmps* above). *setksmps* should be used before any other opcodes (but allowed after *xin*), otherwise unpredictable results may occur.

The input parameters can be read with *xin*, and the output is written by *xout* opcode. Only one instance of these units should be used, as *xout* overwrites and does not accumulate the output. The number and type of arguments for *xin* and *xout* must be the same as in the declaration of the user-defined opcode block (see tables above).

The input and output arguments must agree with the definition both in number (except if the optional i-time input is used) and type. An optional i-time input parameter (*iksmps*) is automatically added to the

*intypes* list, and (similarly to `setksmps`) sets the local `ksmps` value.

## Performance

The syntax of a user-defined opcode block is as follows:

```
opcode name, outtypes, intypes
xinarg1 [, xinarg2] [, xinarg3] ... [xinargN]  xin
[setksmps iksmps]
... the rest of the instrument's code.
xout xoutarg1 [, xoutarg2] [, xoutarg3] ... [xoutargN]
endop
```

The new opcode can then be used with the usual syntax:

```
[xoutarg1] [, xoutarg2] ... [xoutargN] name [xinarg1] [, xinarg2] ... [xinargN] [, iksmps]
```

### Note

The opcode call is always executed both at initialization and performance time, even if there are no a- or k-rate arguments. If there are many user opcode calls that are known to have no effect at performance time in an instrument, then it may save some CPU time to jump over groups of such opcodes with `kgoto`.

## Examples

Here is an example of a user-defined opcode. It uses the file `opcode.csd` [`examples/opcode_example.csd`].

### Example 559. Example of a user-defined opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# oscbnk

oscbnk — Mixes the output of any number of oscillators.

## Description

This unit generator mixes the output of any number of oscillators. The frequency, phase, and amplitude of each oscillator can be modulated by two LFOs (all oscillators have a separate set of LFOs, with different phase and frequency); additionally, the output of each oscillator can be filtered through an optional parametric equalizer (also controlled by the LFOs). This opcode is most useful for rendering ensemble (strings, choir, etc.) instruments.

Although the LFOs run at k-rate, amplitude, phase and filter modulation are interpolated internally, so it is possible (and recommended in most cases) to use this unit at low (~1000 Hz) control rates without audible quality degradation.

The start phase and frequency of all oscillators and LFOs can be set by a built-in seedable 31-bit random number generator, or specified manually in a function table (GEN2).

## Syntax

```
ares oscbnk kcps, kamd, kfmd, kpmd, iovrlap, iseed, k11minf, k11maxf, \
      k12minf, k12maxf, ilfomode, keqminf, keqmaxf, keqminl, keqmaxl, \
      keqminq, keqmaxq, ieqmode, kfn [, il1fn] [, il2fn] [, ieqffn] \
      [, ieqlfn] [, ieqqfn] [, itabl] [, ioutfn]
```

## Initialization

*iovrlap* -- Number of oscillator units.

*iseed* -- Seed value for random number generator (positive integer in the range 1 to 2147483646 ( $2^{31} - 2$ )). *iseed*  $\leq 0$  seeds from the current time.

*ieqmode* -- Parametric equalizer mode

- -1: disable EQ (faster)
- 0: peak
- 1: low shelf
- 2: high shelf
- 3: peak (filter interpolation disabled)
- 4: low shelf (interpolation disabled)
- 5: high shelf (interpolation disabled)

The non-interpolated modes are faster, and in some cases (e.g. high shelf filter at low cutoff frequencies) also more stable; however, interpolation is useful for avoiding “zipper noise” at low control rates.

*ilfomode* -- LFO modulation mode, sum of:

- 128: LFO1 to frequency
- 64: LFO1 to amplitude
- 32: LFO1 to phase
- 16: LFO1 to EQ
- 8: LFO2 to frequency
- 4: LFO2 to amplitude
- 2: LFO2 to phase
- 1: LFO2 to EQ

If an LFO does not modulate anything, it is not calculated, and the ftable number (*il1fn* or *il2fn*) can be omitted.

*il1fn* (optional: default=0) -- LFO1 function table number. The waveform in this table has to be normalized (absolute value <= 1), and is read with linear interpolation.

*il2fn* (optional: default=0) -- LFO2 function table number. The waveform in this table has to be normalized, and is read with linear interpolation.

*ieqfn*, *ieqlfn*, *ieqqfn* (optional: default=0) -- Lookup tables for EQ frequency, level, and Q (optional if EQ is disabled). Table read position is 0 if the modulator signal is less than, or equal to -1, (table length / 2) if the modulator signal is zero, and the guard point if the modulator signal is greater than, or equal to 1. These tables have to be normalized to the range 0 - 1, and have an extended guard point (table length = power of two + 1). All tables are read with linear interpolation.

*itabl* (optional: default=0) -- Function table storing phase and frequency values for all oscillators (optional). The values in this table are in the following order (5 for each oscillator unit):

oscillator phase, lfo1 phase, lfo1 frequency, lfo2 phase, lfo2 frequency, ...

All values are in the range 0 to 1; if the specified number is greater than 1, it is wrapped (phase) or limited (frequency) to the allowed range. A negative value (or end of table) will use the output of the random number generator. The random seed is always updated (even if no random number was used), so switching one value between random and fixed will not change others.

*ioutfn* (optional: default=0) -- Function table to write phase and frequency values (optional). The format is the same as in the case of *itabl*. This table is useful when experimenting with random numbers to record the best values.

The two optional tables (*itabl* and *ioutfn*) are accessed only at i-time. This is useful to know, as the tables can be safely overwritten after opcode initialization, which allows precalculating parameters at i-time and storing in a temporary table before *oscblk* initialization.

## Performance

*ares* -- Output signal.

*kcps* -- Oscillator frequency in Hz.

*kamd* -- AM depth (0 - 1).

(AM output) = (AM input) \* ((1 - (AM depth)) + (AM depth) \* (modulator))

If *ilfomode* isn't set to modulate the amplitude, then (AM output) = (AM input) regardless of the value of *kamd*. That means that *kamd* will have no effect.

Note: Amplitude modulation is applied before the parametric equalizer.

*kfmd* -- FM depth (in Hz).

*kpmf* -- Phase modulation depth.

*kl1minf*, *kl1maxf* -- LFO1 minimum and maximum frequency in Hz.

*kl2minf*, *kl2maxf* -- LFO2 minimum and maximum frequency in Hz. (Note: oscillator and LFO frequencies are allowed to be zero or negative.)

*keqminf*, *keqmaxf* -- Parametric equalizer minimum and maximum frequency in Hz.

*keqminl*, *keqmaxl* -- Parametric equalizer minimum and maximum level.

*keqminq*, *keqmaxq* -- Parametric equalizer minimum and maximum Q.

*kfn* -- Oscillator waveform table. Table number can be changed at k-rate (this is useful to select from a set of band-limited tables generated by GEN30, to avoid aliasing). The table is read with linear interpolation.

## Note

*oscbnk* uses the same random number generator as *rnd31*. So reading *its documentation* is also recommended.

# Examples

Here is an example of *oscbnk* opcode. It uses the file *oscbnk.csd* [examples/oscbnk.csd].

### Example 560. Example of the oscbnk opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

New in version 4.15

Updated April 2002 by Istvan Varga

# oscil1

`oscil1` — Accesses table values by incremental sampling.

## Description

Accesses table values by incremental sampling.

## Syntax

```
kres oscil1 idel, kamp, idur [, ifn]
```

## Initialization

*idel* -- delay in seconds before *oscil1* incremental sampling begins.

*idur* -- duration in seconds to sample through the *oscil1* table just once. A zero or negative value will cause all initialization to be skipped.

*ifn* -- (optional) function table number. *tablei*, *oscil1i* require the extended guard point. The number defaults to -1 which indicates a sinewave.

## Performance

*kamp* -- amplitude factor.

*oscil1* accesses values by sampling once through the function table at a rate determined by *idur*. For the first *idel* seconds, the point of scan will reside at the first location of the table; it will then begin moving through the table at a constant rate, reaching the end in another *idur* seconds; from that time on (i.e. after *idel* + *idur* seconds) it will remain pointing at the last location. Each value obtained from sampling is then multiplied by an amplitude factor *kamp* before being written into the result.

## Examples

Here is an example of the *oscil1* opcode. It uses the file *oscil1.csd* [examples/oscil1.csd].

### Example 561. Example of the oscil1 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

i1    1.00000
i1    0.50000
```

## See Also

*table, tablei, table3, oscilli, osciln*

# oscil1i

`oscil1i` — Accesses table values by incremental sampling with linear interpolation.

## Description

Accesses table values by incremental sampling with linear interpolation.

## Syntax

```
kres oscil1i idel, kamp, idur [, ifn]
```

## Initialization

*idel* -- delay in seconds before *oscil1i* incremental sampling begins.

*idur* -- duration in seconds to sample through the *oscil1i* table just once. A zero or negative value will cause all initialization to be skipped.

*ifn* -- (optional) function table number. *oscil1i* requires the extended guard point. The default value is -1 indicating a sine wave.

## Performance

*kamp* -- amplitude factor

*oscil1i* is an interpolating unit in which the fractional part of index is used to interpolate between adjacent table entries. The smoothness gained by interpolation is at some small cost in execution time (see also *oscili*, etc.), but the interpolating and non-interpolating units are otherwise interchangeable.

## Examples

Here is an example of the *oscil1i* opcode. It uses the file *oscil1i.csd* [examples/oscil1i.csd].

### Example 562. Example of the oscil1i opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# oscil3

oscil3 — A simple oscillator with cubic interpolation.

## Description

*oscil3* reads table *ifn* sequentially and repeatedly at a frequency *xcps*. The amplitude is scaled by *xamp*. Cubic interpolation is applied for table look up from internal phase values.

## Syntax

```
ares oscil3 xamp, xcps [, ifn, iphs]
```

```
kres oscil3 kamp, kcps [, ifn, iphs]
```

## Initialization

*ifn* (optional) -- function table number. Requires a wrap-around guard point. Defaults to -1 indicating a sinewave.

*iphs* (optional) -- initial phase of sampling, expressed as a fraction of a cycle (0 to 1). A negative value will cause phase initialization to be skipped. The default value is 0.

## Performance

*kamp, xamp* -- amplitude

*kcps, xcps* -- frequency in cycles per second.

*oscil3* is identical to *oscili*, except that it uses cubic interpolation.

Table *ifn* is incrementally sampled modulo the table length and the value obtained is multiplied by *amp*.

If you need to change the oscillator table with a k-rate signal, you can use *oscilkt*.

## Examples

Here is an example of the oscil3 opcode. It uses the file *oscil3.csd* [examples/oscil3.csd].

### Example 563. Example of the oscil3 opcode.

# oscil

oscil — A simple oscillator.

## Description

*oscil* reads table *ifn* sequentially and repeatedly at a frequency *xcps*. The amplitude is scaled by *xamp*.

## Syntax

```
ares oscil xamp, xcps [, ifn, iphs]  
kres oscil kamp, kcps [, ifn, iphs]
```

## Initialization

*ifn* -- (optional) function table number. Requires a wrap-around guard point. The table number defaults to -1 which indicates a sinewave.

*iphs* (optional, default=0) -- initial phase of sampling, expressed as a fraction of a cycle (0 to 1). A negative value will cause phase initialization to be skipped. The default value is 0.

## Performance

*kamp, xamp* -- amplitude

*kcps, xcps* -- frequency in cycles per second.

The *oscil* opcode generates periodic control (or audio) signals consisting of the value of *kamp* (*xamp*) times the value returned from control rate (audio rate) sampling of a stored function table. The internal phase is simultaneously advanced in accordance with the *kcps* or *xcps* input value.

Table *ifn* is incrementally sampled modulo the table length and the value obtained is multiplied by *amp*.

If you need to change the oscillator table with a k-rate signal, you can use *oscilikt*.

## Examples

Here is an example of the *oscil* opcode. It uses the file *oscil.csd* [examples/oscil.csd].

### Example 564. Example of the oscil opcode.

# oscili

oscili — A simple oscillator with linear interpolation.

## Description

*oscili* reads table *ifn* sequentially and repeatedly at a frequency *xcps*. The amplitude is scaled by *xamp*. Linear interpolation is applied for table look up from internal phase values.

## Syntax

```
ares oscili xamp, xcps[, ifn, iphs]
```

```
kres oscili kamp, kcps[, ifn, iphs]
```

## Initialization

*ifn*(optional) -- function table number. Requires a wrap-around guard point. The table number defaults to -1 which indicates a sine wave.

*iphs* (optional) -- initial phase of sampling, expressed as a fraction of a cycle (0 to 1). A negative value will cause phase initialization to be skipped. The default value is 0.

## Performance

*kamp, xamp* -- amplitude

*kcps, xcps* -- frequency in cycles per second.

*oscili* differs from *oscil* in that the standard procedure of using a truncated phase as a sampling index is here replaced by a process that interpolates between two successive lookups. Interpolating generators will produce a noticeably cleaner output signal, but they may take as much as twice as long to run. Adequate accuracy can also be gained without the time cost of interpolation by using large stored function tables of 2K, 4K or 8K points if the space is available.

Table *ifn* is incrementally sampled modulo the table length and the value obtained is multiplied by *amp*.

If you need to change the oscillator table with a k-rate signal, you can use *oscilikt*.

## Examples

Here is an example of the oscili opcode. It uses the file *oscili.csd* [examples/oscili.csd].

# oscilikt

`oscilikt` — A linearly interpolated oscillator that allows changing the table number at k-rate.

## Description

`oscilikt` is very similar to `oscili`, but allows changing the table number at k-rate. It is slightly slower than `oscili` (especially with high control rate), although also more accurate as it uses a 31-bit phase accumulator, as opposed to the 24-bit one used by `oscili`.

## Syntax

```
ares oscilikt xamp, xcps, kfn [, iphs] [, istor]
```

```
kres oscilikt kamp, kcps, kfn [, iphs] [, istor]
```

## Initialization

*iphs* (optional, defaults to 0) -- initial phase in the range 0 to 1. Other values are wrapped to the allowed range.

*istor* (optional, defaults to 0) -- skip initialization.

## Performance

*kamp*, *xamp* -- amplitude.

*kcps*, *xcps* -- frequency in Hz. Zero and negative values are allowed. However, the absolute value must be less than *sr* (and recommended to be less than *sr*/2).

*kfn* -- function table number. Can be varied at control rate (useful to “morph” waveforms, or select from a set of band-limited tables generated by *GEN30*).

## Examples

Here is an example of the `oscilikt` opcode. It uses the file `oscilikt.csd` [examples/oscilikt.cs].

### Example 566. Example of the `oscilikt` opcode.

# osciliktp

`osciliktp` — A linearly interpolated oscillator that allows phase modulation.

## Description

`osciliktp` allows phase modulation (which is actually implemented as k-rate frequency modulation, by differentiating phase input). The disadvantage is that there is no amplitude control, and frequency can be varied only at the control-rate. This opcode can be faster or slower than `oscilikt`, depending on the control-rate.

## Syntax

```
ares osciliktp kcps, kfn, kphs [, istor]
```

## Initialization

*istor* (optional, defaults to 0) -- Skips initialization.

## Performance

*ares* -- audio-rate output signal.

*kcps* -- frequency in Hz. Zero and negative values are allowed. However, the absolute value must be less than *sr* (and recommended to be less than *sr*/2).

*kfn* -- function table number. Can be varied at control rate (useful to “morph” waveforms, or select from a set of band-limited tables generated by *GEN30*).

*kphs* -- phase (k-rate), the expected range is 0 to 1. The absolute value of the difference of the current and previous value of *kphs* must be less than *ksmps*.

## Examples

Here is an example of the `osciliktp` opcode. It uses the file `osciliktp.csd` [examples/osciliktp.csd].

### Example 567. Example of the `osciliktp` opcode.

# oscilikts

*oscilikts* — A linearly interpolated oscillator with sync status that allows changing the table number at k-rate.

## Description

*oscilikts* is the same as *oscilikt*. Except it has a sync input that can be used to re-initialize the oscillator to a k-rate phase value. It is slower than *oscilikt* and *osciliktp*.

## Syntax

```
ares oscilikts xamp, xcps, kfn, async, kphs [, istor]
```

## Initialization

*istor* (optional, defaults to 0) -- skip initialization.

## Performance

*xamp* -- amplitude.

*xcps* -- frequency in Hz. Zero and negative values are allowed. However, the absolute value must be less than *sr* (and recommended to be less than *sr/2*).

*kfn* -- function table number. Can be varied at control rate (useful to “morph” waveforms, or select from a set of band-limited tables generated by *GEN30*).

*async* -- any positive value resets the phase of *oscilikts* to *kphs*. Zero or negative values have no effect.

*kphs* -- sets the phase, initially and when it is re-initialized with *async*.

## Examples

Here is an example of the *oscilikts* opcode. It uses the file *oscilikts.csd* [examples/oscilikts.csd].

### Example 568. Example of the oscilikts opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# osciln

osciln — Accesses table values at a user-defined frequency.

## Description

Accesses table values at a user-defined frequency. This opcode can also be written as *oscilx*.

## Syntax

```
ares osciln kamp, ifrq, ifn, itimes
```

## Initialization

*ifrq, itimes* -- rate and number of times through the stored table.

*ifn* -- function table number.

## Performance

*kamp* -- amplitude factor

*osciln* will sample several times through the stored table at a rate of *ifrq* times per second, after which it will output zeros. Generates audio signals only, with output values scaled by *kamp*.

## Examples

Here is an example of the osciln opcode. It uses the file *osciln.csd* [examples/osciln.csd].

### Example 569. Example of the osciln opcode.

# oscils

oscils — A simple, fast sine oscillator

## Description

Simple, fast sine oscillator, that uses only one multiply, and two add operations to generate one sample of output, and does not require a function table.

## Syntax

```
ares oscils iamp, icps, iphs [, iflg]
```

## Initialization

*iamp* -- output amplitude.

*icps* -- frequency in Hz (may be zero or negative, however the absolute value must be less than *sr/2*).

*iphs* -- start phase between 0 and 1.

*iflg* -- sum of the following values:

- *2*: use double precision even if Csound was compiled to use floats. This improves quality (especially in the case of long performance time), but may be up to twice as slow.
- *1*: skip initialization.

## Performance

*ares* -- audio output

## Examples

Here is an example of the oscils opcode. It uses the file *oscils.csd* [examples/oscils.csd].

### Example 570. Example of the oscils opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## oscilx

oscilx — Same as the osciln opcode.

## Description

Same as the *osciln* opcode.

# OSCinit

OSCinit — Start a listening process for OSC messages to a particular port.

## Description

Starts a listening process, which can be used by OSCListen.

## Syntax

```
ihandle oscinit iport
```

## Initialization

*ihandle* -- handle returned that can be passed to any number of OSCListen opcodes to receive messages on this port.

*iport* -- the port on which to listen.

## Performance

The listener runs in the background. See OSCListen for details.

## Example

The example shows a pair of floating point numbers being received on port 7770.

```
sr = 44100
ksmps = 100
nchnls = 2

gihandle oscinit 7770

instr 1
    kf1 init 0
    kf2 init 0
nxtmsg:
    kk OSCListen gihandle, "/foo/bar", "ff", kf1, kf2
    if (kk == 0) goto ex
    printk 0,kf1
    printk 0,kf2
    kgoto nxtmsg
ex:
    endin
```

# OSClisten

OSClisten — Listen for OSC messages to a particular path.

## Description

On each k-cycle looks to see if an OSC message has been send to a given path of a given type.

## Syntax

```
kans osclisten ihandle, idest, itype [, xdata1, xdata2, ...]
```

## Initialization

*ihandle* -- a handle returned by an earlier call to OSCinit, to associate OSClisten with a particular port number.

*idest* -- a string that is the destination address. This takes the form of a file name with directories. Csound uses this address to decide if messages are meant for csound.

*itype* -- a string that indicates the types of the optional arguments that are to be read. The string can contain the characters "cdfhis" which stand for character, double, float, 64-bit integer, 32-bit integer, and string. All types other than 's' require a k-rate variable, while 's' requires a string variable.

A handler is inserted into the listener (see OSCinit) to intercept messages of this pattern.

## Performance

*kans* -- set to 1 if a new message was received, or zero if not. If multiple messages are received in a single control period, the messages are buffered, and OSClisten can be called again until zero is returned.

If there was a message the *xdata* variables are set to the incoming values, as interpreted by the *itype* parameter. Note that although the *xdata* variables are on the right of an operation they are actually outputs, and so must be variables of type k, gk, S, or gS, and may need to be declared with init, or = in the case of string variables, before calling OSClisten.

## Example

The example shows a pair of floating point numbers being received on port 7770.

```
sr = 44100
ksmps = 100
nchnls = 2

gihandle OSCinit 7770

instr 1
    kf1 init 0
    kf2 init 0
nxtmsg:
    kk osclisten gihandle, "/foo/bar", "ff", kf1, kf2
if (kk == 0) goto ex
    printk 0,kf1
    printk 0,kf2
```

```
    kgoto nxtmsg
ex:
  endin
```

Below are two .csd files which demonstrate the usage of the OSC opcodes. They use the files *OS-Cmidisend.csd* [examples/OSCMidisend.csd] and *OSCMidircv.csd* [examples/OSCMidircv.csd].

### Example 571. Example of the OSC opcodes.

The following two .csd files demonstrate the usage of the OSC opcodes in csound. The first file, *OS-Cmidisend.csd* [examples/OSCMidisend.csd], transforms received real-time MIDI messages into OSC data. The second file, *OSCMidircv.csd* [examples/OSCMidircv.csd], can take these OSC messages, and interpret them to generate sound from note messages, and store controller values. It will use controller number 7 to control volume. Note that these files are designed to be on the same machine, but if a different host address (in the IPADDRESS macro) is used, they can be separate machines on a network, or connected through the internet.

CSD file to send OSC messages:

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out   Audio in
-odac          -iadc    ;;;RT audio I/O
</CsOptions>
<CsInstruments>

sr      =  44100
ksmps   =  128
nchnls  =  1

; Example by David Akbari 2007
; Modified by Jonathan Murphy
; Use this file to generate OSC events for OSCmidircv.csd

# OSCsend

OSCsend — Sends data to other processes using the OSC protocol

## Description

Uses the OSC protocol to send message to other OSC listening processes.

## Syntax

```
oscsend kwhen, ihost, iport, idestination, itype [, kdata1, kdata2, ...]
```

## Initialization

*ihost* -- a string that is the intended host computer domain name. An empty string is interpreted as the current computer.

*iport* -- the number of the port that is used for the communication.

*idest* -- a string that is the destination address. This takes the form of a file name with directories. Csound just passes this string to the raw sending code and makes no interpretation.

*itype* -- a string that indicates the types of the optional arguments that are read at k-rate. The string can contain the characters "bcdfilmst" which stand for Boolean, character, double, float, 32-bit integer, 64-bit integer, MIDI, string and timestamp.

## Performance

*kwhen* -- a message is sent whenever this value changes. A message will always be sent on the first call.

The data is taken from the k-values that follow the format string. In a similar way to a printf format, the characters in order determine how the argument is interpreted. Note that a time stamp takes two arguments.

## Example

The example shows a simple instrument, which when called, sends a group of 3 messages to a computer called "xenakis", on port 7770, to be read by a process that recognises /foo/bar as its address.

```
instr 1
  oscsend    1, "xenakis.cs.bath.ac.uk", 7770, "/foo/bar", "sis", "FOO", 42, "bar"
endin
```

See the entry for *OSClisten*, for an example of send/ receive usage using OSC.

## out32

`out32` — Writes 32-channel audio data to an external device or stream.

### Description

Writes 32-channel audio data to an external device or stream.

### Syntax

```
out32 asig1, asig2, asig3, asig4, asig5, asig6, asig7, asig8, asig10, \
asig11, asig12, asig13, asig14, asig15, asig16, asig17, asig18, \
asig19, asig20, asig21, asig22, asig23, asig24, asig25, asig26, \
asig27, asig28, asig29, asig30, asig31, asig32
```

### Performance

*out32* outputs 32 channels of audio.

# Out

**out** — Writes audio data to an external device or stream.

## Description

Writes audio data to an external device or stream, either from audio variables or from an audio array.

## Syntax

```
out asig1[, asig2,....]  
  
out aarray
```

## Performance

Sends audio samples to an accumulating output buffer (created at the beginning of performance) which serves to collect the output of all active instruments before the sound is written to disk. There can be any number of these output units in an instrument.

The type (mono, stereo, quad, hex, or oct) should agree with *nchnls*. But as of version 3.50, Csound will attempt to change an incorrect opcode to agree with *nchnls* statement.

## Examples

Here is an example of the out opcode. It uses the file *out.csd* [examples/out.csd].

### Example 572. Example of the out opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# outc

outc — Writes audio data with an arbitrary number of channels to an external device or stream.

## Description

Writes audio data with an arbitrary number of channels to an external device or stream.

## Syntax

```
outc asig1 [, asig2] [...]
```

## Performance

*outc* outputs as many channels as provided. Any channels greater than *nchnls* are ignored. Zeros are added as necessary

## Examples

Here is an example of the outc opcode. It uses the file *outc.csd* [examples/outc.csd].

### Example 573. Example of the outc opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>

# outch

**outch** — Writes multi-channel audio data, with user-controllable channels, to an external device or stream.

## Description

Writes multi-channel audio data, with user-controllable channels, to an external device or stream.

## Syntax

```
outch kchan1, asig1 [, kchan2] [, asig2] [...]
```

## Performance

*outch* outputs *asig1* on the channel determined by *kchan1*, *asig2* on the channel determined by *kchan2*, etc.

### Note

The highest number for *kchanX* available for use with *outch* depends on *nchnls*. If *kchanX* is greater than *nchnls*, *asigX* will be silent. Note that *outch* will give a warning but not an error in this case.

## Examples

Here is an example of the *outch* opcode. It uses the file *outch.csd* [examples/outch.csd].

### Example 574. Example of the outch opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## outh

outh — Writes 6-channel audio data to an external device or stream.

## Description

Writes 6-channel audio data to an external device or stream.

## Syntax

```
outh asig1, asig2, asig3, asig4, asig5, asig6
```

## Performance

Sends 6-channel audio samples to an accumulating output buffer (created at the beginning of performance) which serves to collect the output of all active instruments before the sound is written to disk. There can be any number of these output units in an instrument.

The type (mono, stereo, quad, hex, or oct) should agree with *nchnls*. But as of version 3.50, Csound will attempt to change an incorrect opcode to agree with *nchnls* statement.

# outiat

outiat — Sends MIDI aftertouch messages at i-rate.

## Description

Sends MIDI aftertouch messages at i-rate.

## Syntax

```
outiat ichn, ivalue, imin, imax
```

## Initialization

*ichn* -- MIDI channel number (1-16)

*ivalue* -- floating point value

*imin* -- minimum floating point value (converted in MIDI integer value 0)

*imax* -- maximum floating point value (converted in MIDI integer value 127 (7 bit))

## Performance

*outiat* (i-rate aftertouch output) sends aftertouch messages. It works only with MIDI instruments which recognize them. It can drive a different value of a parameter for each note currently active.

It can scale an i-value floating-point argument according to the *imin* and *imax* values. For example, set *imin* = 1.0 and *imax* = 2.0. When the *ivalue* argument receives a 2.0 value, the opcode will send a 127 value to the MIDI OUT device. When the *ivalue* argument receives a 1.0 value, it will send a 0 value. i-rate opcodes send their message once during instrument initialization.

## Examples

Here is an example of the outiat opcode. It uses the file *outiat.csd* [examples/outiat.csd].

### Example 576. Example of the outiat opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# outic14

outic14 — Sends 14-bit MIDI controller output at i-rate.

## Description

Sends 14-bit MIDI controller output at i-rate.

## Syntax

```
outic14 ichn, imsb, ilsb, ivalue, imin, imax
```

## Initialization

*ichn* -- MIDI channel number (1-16)

*imsb* -- most significant byte controller number when using 14-bit parameters (0-127)

*ilsb* -- least significant byte controller number when using 14-bit parameters (0-127)

*ivalue* -- floating point value

*imin* -- minimum floating point value (converted in MIDI integer value 0)

*imax* -- maximum floating point value (converted in MIDI integer value 16383 (14-bit))

## Performance

*outic14* (i-rate MIDI 14-bit controller output) sends a pair of controller messages. This opcode can drive 14-bit parameters on MIDI instruments that recognize them. The first control message contains the most significant byte of *ivalue* argument while the second message contains the less significant byte. *imsb* and *ilsb* are the number of the most and less significant controller.

This opcode can drive a different value of a parameter for each note currently active.

It can scale an i-value floating-point argument according to the *imin* and *imax* values. For example, set *imin* = 1.0 and *imax* = 2.0. When the *ivalue* argument receives a 2.0 value, the opcode will send a 127 value to the MIDI OUT device. When the *ivalue* argument receives a 1.0 value, it will send a 0 value. i-rate opcodes send their message once during instrument initialization.

# outic

`outic` — Sends MIDI controller output at i-rate.

## Description

Sends MIDI controller output at i-rate.

## Syntax

```
outic ichn, inum, ivalue, imin, imax
```

## Initialization

*ichn* -- MIDI channel number (1-16)

*inum* -- controller number (0-127 for example 1 = ModWheel; 2 = BreathControl etc.)

*ivalue* -- floating point value

*imin* -- minimum floating point value (converted in MIDI integer value 0)

*imax* -- maximum floating point value (converted in MIDI integer value 127 (7 bit))

## Performance

`outic` (i-rate MIDI controller output) sends controller messages to the MIDI OUT device. It works only with MIDI instruments which recognize them. It can drive a different value of a parameter for each note currently active.

It can scale an i-value floating-point argument according to the *imin* and *imax* values. For example, set *imin* = 1.0 and *imax* = 2.0. When the *ivalue* argument receives a 2.0 value, the opcode will send a 127 value to the MIDI OUT device. When the *ivalue* argument receives a 1.0 value, it will send a 0 value. i-rate opcodes send their message once during instrument initialization.

## Examples

Here is an example of the `outic` opcode. It uses the file `outic.csd` [examples/outic.csd].

### Example 577. Example of the `outic` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# outipat

`outipat` — Sends polyphonic MIDI aftertouch messages at i-rate.

## Description

Sends polyphonic MIDI aftertouch messages at i-rate.

## Syntax

```
outipat ichn, inotenum, ivalue, imin, imax
```

## Initialization

*ichn* -- MIDI channel number (1-16)

*inotenum* -- MIDI note number (used in polyphonic aftertouch messages)

*ivalue* -- floating point value

*imin* -- minimum floating point value (converted in MIDI integer value 0)

*imax* -- maximum floating point value (converted in MIDI integer value 127 (7 bit))

## Performance

`outipat` (i-rate polyphonic aftertouch output) sends polyphonic aftertouch messages. It works only with MIDI instruments which recognize them. It can drive a different value of a parameter for each note currently active.

It can scale an i-value floating-point argument according to the *imin* and *imax* values. For example, set *imin* = 1.0 and *imax* = 2.0. When the *ivalue* argument receives a 2.0 value, the opcode will send a 127 value to the MIDI OUT device. When the *ivalue* argument receives a 1.0 value, it will send a 0 value. i-rate opcodes send their message once during instrument initialization.

# outipb

outipb — Sends MIDI pitch-bend messages at i-rate.

## Description

Sends MIDI pitch-bend messages at i-rate.

## Syntax

```
outipb ichn, ivalue, imin, imax
```

## Initialization

*ichn* -- MIDI channel number (1-16)

*ivalue* -- floating point value

*imin* -- minimum floating point value (converted in MIDI integer value 0)

*imax* -- maximum floating point value (converted in MIDI integer value 127 (7 bit))

## Performance

*outipb* (i-rate pitch bend output) sends pitch bend messages. It works only with MIDI instruments which recognize them. It can drive a different value of a parameter for each note currently active.

It can scale an i-value floating-point argument according to the *imin* and *imax* values. For example, set *imin* = 1.0 and *imax* = 2.0. When the *ivalue* argument receives a 2.0 value, the opcode will send a 127 value to the MIDI OUT device. When the *ivalue* argument receives a 1.0 value, it will send a 0 value. i-rate opcodes send their message once during instrument initialization.

## Examples

Here is an example of the outipb opcode. It uses the file *outipb.csd* [examples/outipb.csd].

### Example 578. Example of the outipb opcode.

# outkat

outkat — Sends MIDI aftertouch messages at k-rate.

## Description

Sends MIDI aftertouch messages at k-rate.

## Syntax

```
outkat kchn, kvalue, kmin, kmax
```

## Performance

*kchn* -- MIDI channel number (1-16)

*kvalue* -- floating point value

*kmin* -- minimum floating point value (converted in MIDI integer value 0)

*kmax* -- maximum floating point value (converted in MIDI integer value 127)

*outkat* (k-rate aftertouch output) sends aftertouch messages. It works only with MIDI instruments which recognize them. It can drive a different value of a parameter for each note currently active.

It can scale the k-value floating-point argument according to the *kmin* and *kmax* values. For example: set *kmin* = 1.0 and *kmax* = 2.0. When the *kvalue* argument receives a 2.0 value, the opcode will send a 127 value to the MIDI OUT device. When the *kvalue* argument receives a 1.0 value, it will send a 0 value. k-rate opcodes send a message each time the MIDI converted value of argument *kvalue* changes.

## Examples

Here is an example of the outkat opcode. It uses the file *outkat.csd* [examples/outkat.csd].

### Example 580. Example of the outkat opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# outkc14

`outkc14` — Sends 14-bit MIDI controller output at k-rate.

## Description

Sends 14-bit MIDI controller output at k-rate.

## Syntax

```
outkc14 kchn, kmsb, klsb, kvalue, kmin, kmax
```

## Performance

*kchn* -- MIDI channel number (1-16)

*kmsb* -- most significant byte controller number when using 14-bit parameters (0-127)

*klsb* -- least significant byte controller number when using 14-bit parameters (0-127)

*kvalue* -- floating point value

*kmin* -- minimum floating point value (converted in MIDI integer value 0)

*kmax* -- maximum floating point value (converted in MIDI integer value 16383 (14-bit))

`outkc14` (k-rate MIDI 14-bit controller output) sends a pair of controller messages. It works only with MIDI instruments which recognize them. These opcodes can drive 14-bit parameters on MIDI instruments that recognize them. The first control message contains the most significant byte of *kvalue* argument while the second message contains the less significant byte. *kmsb* and *klsb* are the number of the most and less significant controller.

It can drive a different value of a parameter for each note currently active.

It can scale the k-value floating-point argument according to the *kmin* and *kmax* values. For example: set *kmin* = 1.0 and *kmax* = 2.0. When the *kvalue* argument receives a 2.0 value, the opcode will send a 127 value to the MIDI OUT device. When the *kvalue* argument receives a 1.0 value, it will send a 0 value. k-rate opcodes send a message each time the MIDI converted value of argument *kvalue* changes.

# outkc

outkc — Sends MIDI controller messages at k-rate.

## Description

Sends MIDI controller messages at k-rate.

## Syntax

```
outkc kchn, knum, kvalue, kmin, kmax
```

## Performance

*kchn* -- MIDI channel number (1-16)

*knum* -- controller number (0-127 for example 1 = ModWheel; 2 = BreathControl etc.)

*kvalue* -- floating point value

*kmin* -- minimum floating point value (converted in MIDI integer value 0)

*kmax* -- maximum floating point value (converted in MIDI integer value 127 (7 bit))

*outkc* (k-rate MIDI controller output) sends controller messages to MIDI OUT device. It works only with MIDI instruments which recognize them. It can drive a different value of a parameter for each note currently active.

It can scale the k-value floating-point argument according to the *kmin* and *kmax* values. For example: set *kmin* = 1.0 and *kmax* = 2.0. When the *kvalue* argument receives a 2.0 value, the opcode will send a 127 value to the MIDI OUT device. When the *kvalue* argument receives a 1.0 value, it will send a 0 value. k-rate opcodes send a message each time the MIDI converted value of argument *kvalue* changes.

## Examples

Here is an example of the outkc opcode. It uses the file *outkc.csd* [examples/outkc.csd].

# outkpat

**outkpat** — Sends polyphonic MIDI aftertouch messages at k-rate.

## Description

Sends polyphonic MIDI aftertouch messages at k-rate.

## Syntax

```
outkpat kchn, knotenum, kvalue, kmin, kmax
```

## Performance

*kchn* -- MIDI channel number (1-16)

*knotenum* -- MIDI note number (used in polyphonic aftertouch messages)

*kvalue* -- floating point value

*kmin* -- minimum floating point value (converted in MIDI integer value 0)

*kmax* -- maximum floating point value (converted in MIDI integer value 127 (7 bit))

*outkpat* (k-rate polyphonic aftertouch output) sends polyphonic aftertouch messages. It works only with MIDI instruments which recognize them. It can drive a different value of a parameter for each note currently active.

It can scale the k-value floating-point argument according to the *kmin* and *kmax* values. For example: set *kmin* = 1.0 and *kmax* = 2.0. When the *kvalue* argument receives a 2.0 value, the opcode will send a 127 value to the MIDI OUT device. When the *kvalue* argument receives a 1.0 value, it will send a 0 value. k-rate opcodes send a message each time the MIDI converted value of argument *kvalue* changes.

# outkpc

outkpc — Sends MIDI program change messages at k-rate.

## Description

Sends MIDI program change messages at k-rate.

## Syntax

```
outkpc kchn, kprog, kmin, kmax
```

## Performance

*kchn* -- MIDI channel number (1-16)

*kprog* -- program change number in floating point

*kmin* -- minimum floating point value (converted in MIDI integer value 0)

*kmax* -- maximum floating point value (converted in MIDI integer value 127 (7 bit))

*outkpc* (k-rate program change output) sends program change messages. It works only with MIDI instruments which recognize them. These opcodes can drive a different value of a parameter for each note currently active.

It can scale the k-value floating-point argument according to the *kmin* and *kmax* values. For example: set *kmin* = 1.0 and *kmax* = 2.0. When the *kvalue* argument receives a 2.0 value, the opcode will send a 127 value to the MIDI OUT device. When the *kvalue* argument receives a 1.0 value, it will send a 0 value. k-rate opcodes send a message each time the MIDI converted value of argument *kvalue* changes.

## Examples

Here is an example of the outkpc opcode. It uses the file *outkpc.csd* [examples/outkpc.csd].

### Example 583. Example of the outkpc opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

This example generates a program change and a note on Csound's MIDI output port whenever a note is received on channel 1. Be sure to have something connected to Csound's MIDI out port to hear the result.

# outleta

**outleta** — Sends an arate signal out from an instrument to a named port.

## Description

Sends an arate signal out from an instrument to a named port.

## Syntax

```
outleta Sname, asignal
```

## Initialization

*Sname* -- String name of the outlet port. The name of the outlet is implicitly qualified by the instrument name or number, so it is valid to use the same outlet name in more than one instrument (but not to use the same outlet name twice in one instrument).

## Performance

*asignal* -- audio output signal

During performance, the audio output signal is sent to each instance of an instrument containing an inlet port to which this outlet has been connected using the connect opcode. The signals of all the outlets connected to an inlet are summed in the inlet.

## Examples

Here is an example of the outleta opcode. It uses the file *outleta.csd* [examples/outleta.csd].

### Example 585. Example of the outleta opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## outletf

`outletf` — Sends a frate signal (fsig) out from an instrument to a named port.

## Description

Sends a frate signal (fsig) out from an instrument to a named port.

## Syntax

```
outletf Sname, fsignal
```

## Initialization

*Sname* -- String name of the outlet port. The name of the outlet is implicitly qualified by the instrument name or number, so it is valid to use the same outlet name in more than one instrument (but not to use the same outlet name twice in one instrument).

## Performance

*fsignal* -- frate output signal (fsig)

During performance, the output signal is sent to each instance of an instrument containing an inlet port to which this outlet has been connected using the connect opcode. The signals of all the outlets connected to an inlet are combined in the inlet.

# outletkid

**outletkid** — Sends a krate signal out from an instrument to a named port.

## Description

Sends a krate signal out from an instrument to a named port.

## Syntax

```
outletkid Sname, SinstanceID, ksignal
```

## Initialization

*Sname* -- String name of the outlet port. The name of the outlet is implicitly qualified by the instrument name or number, so it is valid to use the same outlet name in more than one instrument (but not to use the same outlet name twice in one instrument).

*SinstanceID* -- String name of the outlet port's instance ID. This enables the inlet to discriminate between different instances of the outlet, e.g. one instance of the outlet might be created by a note specifying one instance ID, and another instance might be created by a note specifying another ID. This might be used, e.g., to situate difference instances of an instrument at different points in an Ambisonic space in a spatializing effects processor.

## Performance

*ksignal* -- krate output signal

During performance, the krate output signal is sent to each instance of an instrument containing an inlet port to which this outlet has been connected using the connect opcode. The signals of all the outlets connected to an inlet, but only those that have a matching instance ID, are summed in the inlet.

## outo

**outo** — Writes 8-channel audio data to an external device or stream.

## Description

Writes 8-channel audio data to an external device or stream.

## Syntax

```
outo asig1, asig2, asig3, asig4, asig5, asig6, asig7, asig8
```

## Performance

Sends 8-channel audio samples to an accumulating output buffer (created at the beginning of performance) which serves to collect the output of all active instruments before the sound is written to disk. There can be any number of these output units in an instrument.

The type (mono, stereo, quad, hex, or oct) should agree with *nchnls*. But as of version 3.50, Csound will attempt to change an incorrect opcode to agree with *nchnls* statement.

# outq1

outq1 — Writes samples to quad channel 1 of an external device or stream.

## Description

Writes samples to quad channel 1 of an external device or stream.

## Syntax

```
outq1 asig
```

## Performance

Sends audio samples to an accumulating output buffer (created at the beginning of performance) which serves to collect the output of all active instruments before the sound is written to disk. There can be any number of these output units in an instrument.

The type (mono, stereo, quad, hex, or oct) should agree with *nchnls*. But as of version 3.50, Csound will attempt to change an incorrect opcode to agree with the *nchnls* statement. Opcodes can be chosen to direct sound to any particular channel: *outs1* sends to stereo channel 1, *outq3* to quad channel 3, etc.

## Examples

Here is an example of the outq1 opcode. It uses the file *outq1.csd* [examples/outq1.csd].

### Example 587. Example of the outq1 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# outq3

outq3 — Writes samples to quad channel 3 of an external device or stream.

## Description

Writes samples to quad channel 3 of an external device or stream.

## Syntax

```
outq3 asig
```

## Performance

Sends audio samples to an accumulating output buffer (created at the beginning of performance) which serves to collect the output of all active instruments before the sound is written to disk. There can be any number of these output units in an instrument.

The type (mono, stereo, quad, hex, or oct) should agree with *nchnls*. But as of version 3.50, Csound will attempt to change an incorrect opcode to agree with the *nchnls* statement. Opcodes can be chosen to direct sound to any particular channel: *outs1* sends to stereo channel 1, *outq3* to quad channel 3, etc.

## Examples

Here is an example of the outq3 opcode. It uses the file *outq3.csd* [examples/outq3.csd].

# outrg

outrg — Allow output to a range of adjacent audio channels on the audio output device

## Description

*outrg* outputs audio to a range of adjacent audio channels on the audio output device.

## Syntax

```
outrg kstart, aout1 [,aout2, aout3, ..., aoutN]
```

## Performance

*kstart* - the number of the first channel of the output device to be accessed (channel numbers starts with 1, which is the first channel)

*aout1, aout2, ... aoutN* - the arguments containing the audio to be output to the corresponding output channels.

*outrg* allows to output a range of adjacent channels to the output device. *kstart* indicates the first channel to be accessed (channel 1 is the first channel). The user must be sure that the number obtained by summing *kstart* plus the number of accessed channels -1 is  $\leq nchnls$ .

## Examples

Here is an example of the outrg opcode. It uses the file *outrg.csd* [examples/outrg.csd].

### Example 592. Example of the outrg opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# outvalue

**outvalue** — Sends an i-rate or k-rate signal or string to a user-defined channel.

## Description

Sends an irate or k-rate signal or string to a user-defined channel.

## Syntax

```
outvalue "channel name", ivalue  
  
outvalue "channel name", kvalue  
  
outvalue "channel name", "string"
```

## Performance

"*channel name*" -- An integer or string (in double-quotes) representing channel.

*ivalue, kvalue* -- The value that is sent to the channel.

*string* -- The string or string variable that is sent to the channel.

## Examples

Here is an example of the outvalue opcode. It uses the file *outvalue.csd* [examples/outvalue.csd].

### Example 596. Example of the outvalue opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## outz

*outz* — Writes multi-channel audio data from a ZAK array to an external device or stream.

### Description

Writes multi-channel audio data from a ZAK array to an external device or stream.

### Syntax

```
outz ksig1
```

### Performance

*outz* outputs from a ZAK array for *nchnls* of audio.

### See Also

*out32*, *outc*, *outch*, *outx*

# p5gconnect

p5gconnect — Reads data from a P5 Glove controller.

## Description

Opens and at control-rate polls a P5 Glove controller.

## Syntax

**p5gconnect**

## Initialization

The opcode locates a P5 Glove attached to the computer by USB, and starts a listener thread to poll the device.

## Performance

Every control cycle the glove is polled for its position, and finger and button states. These values are read by the *p5gdata* opcode.

## Example

Here is an example of the p5g opcodes. It uses the file *p5g.csd* [examples/p5g.csd].

### Example 597. Example of the p5g opcodes.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# p5gdata

p5gdata — Reads data fields from an external P5 Glove.

## Description

Reads data fields from a P5 Glove controller.

## Syntax

```
kres p5gdata kcontrol
```

## Initialization

This opcode must be used in conjunction with a running *p5gconnect* opcode.

## Performance

*kcontrol* -- the code for which control to read

On each access a particular data item of the P5 glove is read. The currently implemented controls are given below, together with the macro name defined in the file *p5g\_mac*:

- 0 (P5G\_BUTTONS): returns a bit pattern for all buttons that were pressed.
- 1 (P5G\_BUTTON\_A): returns 1 if the button has just been pressed, or 0 otherwise.
- 2 (P5G\_BUTTON\_B): as above.
- 4 (P5G\_BUTTON\_C): as above.
- 8 (P5G\_JUSTPUSH): returns a bit pattern for all buttons that have just been pressed.
- 9 (P5G\_JUSTPU\_A): returns 1 if the A button has just been pressed.
- 10 (P5G\_JUSTPU\_B): as above.
- 12 (P5G\_JUSTPU\_C): as above.
- 16 (P5G\_RELEASED): returns a bit pattern for all buttons that have just been released.
- 17 (P5G\_RELSED\_A): returns 1 if the A button has just been released.
- 18 (P5G\_RELSED\_B): as above.
- 20 (P5G\_RELSED\_C): as above.
- 32 (P5G\_FINGER\_INDEX): returns the clench value of the index finger.
- 33 (P5G\_FINGER\_MIDDLE): as above.
- 34 (P5G\_FINGER\_RING): as above.
- 35 (P5G\_FINGER\_PINKY): as above with little finger.

- 36 (P5G\_FINGER\_THUMB): as above.
- 37 (P5G\_DELTA\_X): The X position of the glove.
- 38 (P5G\_DELTA\_Y): The Y position of the glove.
- 39 (P5G\_DELTA\_Z): The Z position of the glove.
- 40 (P5G\_DELTA\_XR): The X axis change (angle).
- 41 (P5G\_DELTA\_YR): as above.
- 42 (P5G\_DELTA\_ZR): as above.
- 43 (P5G\_ANGLES): The general angle

# p

p — Show the value in a given p-field.

## Description

Show the value in a given p-field.

## Syntax

**p(x)**

This function works at i-rate and k-rate.

## Initialization

x -- the number of the p-field.

## Performance

The value returned by the *p* function is the value in a p-field.

## Examples

Here is an example of the p opcode. It uses the file *p.csd* [examples/p.csd].

### Example 598. Example of the p opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out  Audio in

# pan2

pan2 — Distribute an audio signal across two channels.

## Description

Distribute an audio signal across two channels with a choice of methods.

## Syntax

```
a1, a2 pan2 asig, xp [, imode]
```

## Initialization

*imode* (optional) -- mode of the stereo positioning algorithm. 0 signifies equal power (harmonic) panning, 1 means the square root method, 2 means simple linear and 3 means an alternative equal-power pan (based on an UDO). The default value is 0.

## Performance

*pan2* takes an input signal *asig* and distributes it across two outputs (essentially stereo speakers) according to the control *xp* which can be k- or a-rate. A zero value for *xp* indicates hard left, and a 1 is hard right.

## Example

Here is an example of the *pan2* opcodes. It uses the file *pan2.csd* [examples/pan2.csd].

### Example 599. Example of the pan2 opcodes.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pan

pan — Distribute an audio signal amongst four channels.

## Description

Distribute an audio signal amongst four channels with localization control.

## Syntax

```
a1, a2, a3, a4 pan asig, kx, ky, ifn [, imode] [, ioffset]
```

## Initialization

*ifn* -- function table number of a stored pattern describing the amplitude growth in a speaker channel as sound moves towards it from an adjacent speaker. Requires extended guard-point.

*imode* (optional) -- mode of the *kx*, *ky* position values. 0 signifies raw index mode, 1 means the inputs are normalized (0 - 1). The default value is 0.

*ioffset* (optional) -- offset indicator for *kx*, *ky*. 0 infers the origin to be at channel 3 (left rear); 1 requests an axis shift to the quadraphonic center. The default value is 0.

## Performance

*pan* takes an input signal *asig* and distributes it amongst four outputs (essentially quad speakers) according to the controls *kx* and *ky*. For normalized input (mode=1) and no offset, the four output locations are in order: left-front at (0,1), right-front at (1,1), left-rear at the origin (0,0), and right-rear at (1,0). In the notation (*kx*, *ky*), the coordinates *kx* and *ky*, each ranging 0 - 1, thus control the 'rightness' and 'forwardness' of a sound location.

Movement between speakers is by amplitude variation, controlled by the stored function table *ifn*. As *kx* goes from 0 to 1, the strength of the right-hand signals will grow from the left-most table value to the right-most, while that of the left-hand signals will progress from the right-most table value to the left-most. For a simple linear pan, the table might contain the linear function 0 - 1. A more correct pan that maintains constant power would be obtained by storing the first quadrant of a sinusoid. Since *pan* will scale and truncate *kx* and *ky* in simple table lookup, a medium-large table (say 8193) should be used.

*kx*, *ky* values are not restricted to 0 - 1. A circular motion passing through all four speakers (inscribed) would have a diameter of root 2, and might be defined by a circle of radius  $R = \sqrt{1/2}$  with center at (.5,.5). *kx*, *ky* would then come from  $R\cos(\text{angle})$ ,  $R\sin(\text{angle})$ , with an implicit origin at (.5,.5) (i.e. *ioffset* = 1). Unscaled raw values operate similarly. Sounds can thus be located anywhere in the polar or Cartesian plane; points lying outside the speaker square are projected correctly onto the square's perimeter as for a listener at the center.

## Example

Here is an example of the pan opcodes. It uses the file *pan.csd* [examples/pan.csd].

### Example 600. Example of the pan opcodes.

# pareq

pareq — Implementation of Zoelzer's parametric equalizer filters.

## Description

Implementation of Zoelzer's parametric equalizer filters, with some modifications by the author.

The formula for the low shelf filter is:

```
omega = 2*pi*f/sr  
K    = tan(omega/2)  
  
b0  = 1 + sqrt(2*V)*K + V*K^2  
b1  = 2*(V*K^2 - 1)  
b2  = 1 - sqrt(2*V)*K + V*K^2  
  
a0  = 1 + K/Q + K^2  
a1  = 2*(K^2 - 1)  
a2  = 1 - K/Q + K^2
```

The formula for the high shelf filter is:

```
omega = 2*pi*f/sr  
K    = tan((pi-omega)/2)  
  
b0  = 1 + sqrt(2*V)*K + V*K^2  
b1  = -2*(V*K^2 - 1)  
b2  = 1 - sqrt(2*V)*K + V*K^2  
  
a0  = 1 + K/Q + K^2  
a1  = -2*(K^2 - 1)  
a2  = 1 - K/Q + K^2
```

The formula for the peaking filter is:

```
omega = 2*pi*f/sr  
K    = tan(omega/2)  
  
b0 = 1 + V*K/2 + K^2  
b1 = 2*(K^2 - 1)  
b2 = 1 - V*K/2 + K^2  
  
a0 = 1 + K/Q + K^2  
a1 = 2*(K^2 - 1)  
a2 = 1 - K/Q + K^2
```

## Syntax

```
ares pareq asig, kc, kv, kq [, imode] [, iskip]
```

## Initialization

*imode* (optional, default: 0) -- operating mode

- 0 = Peaking
- 1 = Low Shelving
- 2 = High Shelving

*iskip* (optional, default=0) -- if non zero skip the initialisation of the filter. (New in Csound version 4.23f13 and 5.0)

## Performance

*kc* -- center frequency in peaking mode, corner frequency in shelving mode.

*kv* -- amount of boost or cut. A value less than 1 is a cut. A value greater than 1 is a boost. A value of 1 is a flat response.

*kq* -- Q of the filter ( $\text{sqrt}(.5)$  is no resonance)

*asig* -- the incoming signal

## Examples

Here is an example of the pareq opcode. It uses the file *pareq.csd* [examples/pareq.csd].

### Example 601. Example of the pareq opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# partials

partials — Partial track spectral analysis.

## Description

The partials opcode takes two input PV streaming signals containing AMP\_FREQ and AMP\_PHASE signals (as generated for instance by pvsifd or in the first case, by pvsanal) and performs partial track analysis, as described in Lazzarini et al, "Time-stretching using the Instantaneous Frequency Distribution and Partial Tracking", Proc.of ICMC05, Barcelona. It generates a TRACKS PV streaming signal, containing amplitude, frequency, phase and track ID for each output track. This type of signal will contain a variable number of output tracks, up to the total number of analysis bins contained in the inputs (fftsize/2 + 1 bins). The second input (AMP\_PHASE) is optional, as it can take the same signal as the first input. In this case, however, all phase information will be NULL and resynthesis using phase information cannot be performed.

## Syntax

```
ftrks partials ffr, fphs, kthresh, kminpts, kmaxgap, imaxtracks
```

## Performance

*ftrks* -- output pv stream in TRACKS format

*ffr* -- input pv stream in AMP\_FREQ format

*fphs* -- input pv stream in AMP\_PHASE format

*kthresh* -- analysis threshold factor, defined between -1 and 1. If non-negative, the analysis threshold is taken to be relative to the maximum magnitude in each analysis frame (*kthresh* \* max\_magnitude). If negative, the absolute threshold value is relative to 0dbfs (*kthresh* \* 0dbfs). Tracks below this threshold will be discarded.

*kminpoints* -- minimum number of time points for a detected peak to make a track (1 is the minimum). Since this opcode works with streaming signals, larger numbers will increase the delay between input and output, as we have to wait for the required minimum number of points.

*kmaxgap* -- maximum gap between time-points for track continuation (> 0). Tracks that have no continuation after *kmaxgap* will be discarded.

*imaxtracks* -- maximum number of analysis tracks (number of bins >= *imaxtracks*)

## Example

Here is an example of the partials opcodes. It uses the file *partials.csd* [examples/partials.csd].

### Example 602. Example of the partials opcodes.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# partikkel

*partikkel* — Granular synthesizer with "per grain" control over many of its parameters. Has a sync input to synchronize its internal grain scheduler clock to an external clock source.

## Description

*partikkel* was conceived after reading Curtis Roads' book "Microsound", and the goal was to create an opcode that was capable of all time-domain varieties of granular synthesis described in this book. The idea being that most of the techniques only differ in parameter values, and by having a single opcode that can do all varieties of granular synthesis makes it possible to interpolate between techniques. Granular synthesis is sometimes dubbed particle synthesis, and it was thought apt to name the opcode *partikkel* to distinguish it from other granular opcodes.

Some of the input parameters to *partikkel* are table numbers, pointing to tables where values for the "per grain" parameter changes are stored. *partikkel* can use single-cycle or complex (e.g. sampled sound) waveforms as source waveforms for grains. Each grain consists of a mix of 4 source waveforms. Individual tuning of the base frequency can be done for each of the 4 source waveforms. Frequency modulation inside each grain is enabled via an auxiliary audio input (*awavfm*). Trainlet synthesis is available, and trainlets can be mixed with wavetable based grains. Up to 8 separate audio outputs can be used.

## Syntax

```
a1 [, a2, a3, a4, a5, a6, a7, a8] partikkel agrainfreq, \
    kdistribution, idisttab, async, kenv2amt, ienv2tab, ienv_attack, \
    ienv_decay, ksustain_amount, ka_d_ratio, kduration, kamp, igainmasks, \
    kwavfreq, ksweepshape, iwavfreqstarttab, iwavfreqendtab, awavfm, \
    ifmamptab, kfmenv, icosine, ktraincps, knumpartials, kchroma, \
    ichannelmasks, krandommask, kwaveform1, kwaveform2, kwaveform3, \
    kwaveform4, iwaveamptab, asamplepos1, asamplepos2, asamplepos3, \
    asamplepos4, kwavekey1, kwavekey2, kwavekey3, kwavekey4, imax_grains \
    [, iopcode_id]
```

## Initialization

*idisttab* -- function table number, distribution for random grain displacements over time. The table values are interpreted as "displacement amount" scaled by 1/grainrate. This means that a value of 0.5 in the table will displace a grain by half the grainrate period. The table values are read randomly, and scaled by *kdistribution*. For realistic stochastic results, it is advisable not to use a too small table size, as this limits the amount of possible displacement values. This can also be utilized for other purposes, e.g. using quantized displacement values to work with controlled time displacement from the periodic grain rate. If *kdistribution* is negative, the table values will be read sequentially. A default table might be selected by using -1 as the ftable number, for *idisttab* the default uses a zero distribution (no displacement).

*ienv\_attack* -- function table number, attack shape of grain. Needs extended guard point. A default table might be selected by using -1 as the ftable number, for *ienv\_attack* the default uses a square window (no enveloping).

*ienv\_decay* -- function table number, decay shape of grain. Needs extended guard point. A default table might be selected by using -1 as the ftable number, for *ienv\_decay* the default uses a square window (no enveloping).

*ienv2tab* -- function table number, additional envelope applied to grain, done after attack and decay envelopes. Can be used e.g. for formant synthesis. Needs extended guard point. A default table might be selected by using -1 as the ftable number, for *ienv2tab* the default uses a square window (no envelop-

ing).

*icosine* -- function table number, must contain a cosine, used for trainlets. Table size should be at least 2048 for good quality trainlets.

*igainmasks* -- function table number, gain per grain. The sequence of values in the table is as follows: index 0 is used as a loop start point in reading the values, index 1 is used as a loop end point. Remaining indices contain gain values (normally in range 0 - 1, but other values are allowed, negative values will invert phase of waveform inside grain) for a sequence of grains, these are read at grain rate enabling exact patterns of "gain per grain". The loop start and end points are zero based with an origin at index 2, e.g. a loop start value of 0 and loop end value of 3 will read indices 2,3,4,5 in a loop at grain rate. A default table might be selected by using -1 as the ftable number, for *igainmasks* the default disables gain masking (all grains are given a gain masking value of 1).

*ichannelmasks* -- function table number, see *igainmasks* for a description of how the values in the table are read. Range is 0 to N, where N is the number of output channels minus 1. A value of zero will send the grain to audio output 1 from the opcode. Fractional values are allowed, e.g. a value of 3.5 will mix the grain equally to outputs 4 and 5. The user is responsible for keeping the values in range, no range checking is done. The opcode will crash with out of range values. A default table might be selected by using -1 as the ftable number, for *ichannelmasks* the default disables channel masking (all grains are given a channel masking value of 0 and are sent to *partikkel* audio out 1).

*iwavefreqstarttab* -- function table number, see *igainmasks* for a description of how the values in the table are read. Start frequency multiplicator for each grain. Pitch will glide from start frequency to end frequency following a line or curve as set by *ksweepshape*. A default table might be selected by using -1 as the ftable number, for *iwavefreqstarttab* the default uses a multiplicator of 1, disabling any start frequency modification.

*iwavefreqendtab* -- function table number, see *iwavefreqstarttab*. End frequency multiplicator for each grain. A default table might be selected by using -1 as the ftable number, for *iwavefreqendtab* the default uses a multiplicator of 1, disabling any end frequency modification.

*ifmamptab* -- function table number, see *igainmasks* for a description of how the values in the table are read. Frequency modulation index per grain. The signal *awavfm* will be multiplied by values read from this table. A default table might be selected by using -1 as the ftable number, for *ifmamptab* the default uses 1 as the index multiplicator, enabling fm for all grains.

*iwaveamptab* -- function table number, the indices are read in a similar way to what is used for *igainmasks*. Index 0 is used as a loop start point, and index 1 is used as a loop end point. The rest of the indices are read in groups of 5, where each value represent a gain value for each of the 4 source waveforms, and the 5th value represent trainlet amplitude. A default table might be selected by using -1 as the ftable number, for *iwaveamptab* the default uses an equal mix of all 4 source waveforms (each with an amplitude of 0.5) and setting trainlet amp to zero.

Computation of trainlets can be CPU intensive, and setting *ktrainamp* to zero will skip most of the trainlet computations. Trainlets will be normalized to peak (*ktrainamp*), compensating for amplitude variations caused by variations in *kpartials* and *kchroma*.

*imax\_grains* -- maximum number of grains per k-period. Estimating a large value should not affect performance, exceeding this value will lead to "oldest grains" being deleted.

*iopcode\_id* -- the opcode id, linking an instance of *partikkel* to an instance of *partikkelsync*, the linked *partikkelsync* will output trigger pulses synchronized to *partikkel*'s grain maker scheduler. The default value is zero, which means no connection to any *partikkelsync* instances.

## Performance

*xgrainfreq* -- number of grains per second. A value of zero is allowed, and this will defer all grain scheduling to the sync input.

*async* -- sync input. Input values are added to the phase value of the internal grain maker clock, enabling tempo synchronization with an external clock source. As this is an a-rate signal, inputs are usually pulses of length  $1/sr$ . Using such pulses, the internal phase value can be "nudged" up or down, enabling soft or hard synchronization. Negative input values decrements the internal phase, while positive values in the range 0 to 1 increments the internal phase. An input value of 1 will always make *partikkels* generate a grain. If the value remains at 1, the internal grain scheduler clock will pause but any currently playing grains will still play to end.

*kdistribution* -- periodic or stochastic distribution of grains, 0 = periodic. Stochastic grain displacement is in the range of *kdistribution/grainrate* seconds. The stochastic distribution profile (random distribution) can be set in the *idisttab* table. If *kdistribution* is negative, the result is deterministic time displacement as described by *idisttab* (sequential read of displacement values). Maximum grain displacement in all cases is limited to 10 seconds, and a grain will keep the values (duration, pitch etc) it was given when it was first generated (before time displacement). Since grain displacement is relative to the grain rate, displacement amount is undefined at 0Hz grain rate and *kdistribution* is completely disabled in this case.

*kenv2amt* -- amount of enveloping for the secondary envelope for each grain. Range 0 to 1, where 0 is no secondary enveloping (square window), a value of 0.5 will use an interpolation between a square window and the shape set by *ienv2tab*.

*ksustain\_amount* -- sustain time as fraction of grain duration. I.e. balance between enveloped time(attack+decay) and sustain level time. The sustain level is taken from the last value of the *ienv\_attack* ftable.

*ka\_d\_ratio* -- balance between attack time and decay time. For example, with *ksustain\_amount* set to 0.5 and *ka\_d\_ratio* set to 0.5, the attack envelope of each grain will take 25% of the grain duration, full amplitude (sustain) will be held for 50% of the grain duration, and the decay envelope will take the remaining 25% of the grain duration.

*kduration* -- grain duration in milliseconds.

*kamp* -- amplitude scaling of the opcode's output. Multiplied by per grain amplitude read from *igain-masks*. Source waveform playback inside grains can consume a significant amount of CPU cycles, especially if grain duration is long so that we have a lot of overlapping grains. Setting *kamp* to zero will skip waveform playback inside grains (and not generate any sound, obviously). This can be used as a "soft" bypass method if we want to keep the opcode active but silent for some periods of time.

*kwavfreq* -- transposition scaling. Multiplied with start and end transposition values read from *iwavfreqstarttab* and *iwavfreqendtab*.

*ksweepshape* -- transposition sweep shape, controls the curvature of the transposition sweep. Range 0 to 1. Low values will hold the transposition at the start value longer and then drop to the end value quickly, high values will drop to the end value quickly. A value of 0.5 will give a linear sweep. A value of exactly 0 will bypass sweep and only use the start frequency, while a value of exactly 1 will bypass sweep and only use the end frequency. The sweep generator might be slightly inaccurate in hitting the end frequency when using a steep curve and very long grains.

*awayfm* -- audio input for frequency modulation inside grain.

*kfmenv* -- function table number, envelope for FM modulator signal enabling the modulation index to change over the duration of a grain.

*ktraincps* -- trainlet fundamental frequency.

*knumpartials* -- number of partials in trainlets.

*kchroma* -- chroma of trainlets. A value of 1 give equal amplitude to each partial, higher values will reduce the amplitude of lower partials while strengthening the amplitude of the higher partials.

*krandommask* -- random masking (muting) of individual grains. Range 0 to 1, where a value of 0 will give no masking (all grains are played), and a value of 1 will mute all grains.

*kwaveform1* -- table number for source waveform 1.

*kwaveform2* -- table number for source waveform 2.

*kwaveform3* -- table number for source waveform 3.

*kwaveform4* -- table number for source waveform 4.

*asamplepos1* -- start position for reading source waveform 1 (in range 0..1).

*asamplepos2* -- start position for reading source waveform 2.

*asamplepos3* -- start position for reading source waveform 3.

*asamplepos4* -- start position for reading source waveform 4.

*kwavekey1* -- original key of source waveform 1. Can be used to transpose each source waveform independently.

*kwavekey2* -- as *kwavekey1*, but for source waveform 2.

*kwavekey3* -- as *kwavekey1*, but for source waveform 3.

*kwavekey4* -- as *kwavekey1*, but for source waveform 4.

## Examples

Here is an example of the partikkel opcode. It uses the file *partikkel.csd* [examples/partikkel.csd].

### Example 603. Example of the partikkel opcode.

# partikkelsync

**partikkelsync** — Outputs *partikkel*'s grain scheduler clock pulse and phase to synchronize several instances of the *partikkel* opcode to the same clock source.

## Description

*partikkelsync* is an opcode for outputting *partikkel*'s grain scheduler clock pulse and phase. *partikkelsync*'s output can be used to synchronize other instances of the *partikkel* opcode to the same clock.

## Syntax

```
async [,aphase] partikkelsync iopcode_id
```

## Initialization

*iopcode\_id* -- the opcode id, linking an instance of *partikkel* to an instance of *partikkelsync*.

## Performance

*async* -- trigger pulse signal. Outputs trigger pulses synchronized to a *partikkel* opcode's grain scheduler clock. One trigger pulse is generated for each grain started in the *partikkel* opcode with the same *opcode\_id*. The normal usage would be to send this signal to another *partikkel* opcode's *async* input to synchronize several instances of *partikkel*.

*aphase* -- clock phase. Outputs a linear ramping phase signal. Can be used e.g. for softsynchronization, or just as a phase generator ala *phasor*.

## Example

Here is an example of the partikkelsync opcodes. It uses the file *partikkelsync.csd* [examples/partikkelsync.csd].

### Example 605. Example with soft sync of two partikkel generators.

# passign

passign — Assigns a range of p-fields to ivariables.

## Description

Assigns a range of p-fields to ivariables.

## Syntax

```
ivar1, ... passign [istart]
```

## Initialisation

The optional argument *istart* gives the index of the first p-field to assign. The default value is 1, corresponding to the instrument number.

One of the variables can be a string variable, in which case it is assigned the only string parameter, if there is one, or an error otherwise.

## Performance

*passign* transfers the instrument p-fields to instrument variables, starting with the one identified by the *istart* argument. There should not be more variables than p-fields, but there may be fewer.

## See Also

*assign*,

## Example

Here is an example of the *passign* opcode. It uses the file *passign.csd* [examples/passign.csd].

### Example 606. A variant of toot8.csd that uses passign.

# pcauchy

pcauchy — Cauchy distribution random number generator (positive values only).

## Description

Cauchy distribution random number generator (positive values only). This is an x-class noise generator.

## Syntax

```
ares pcauchy kalpha  
  
ires pcauchy kalpha  
  
kres pcauchy kalpha
```

## Performance

*pcauchy kalpha* -- controls the spread from zero (big kalpha = big spread). Outputs positive numbers only.

For more detailed explanation of these distributions, see:

1. C. Dodge - T.A. Jerse 1985. Computer music. Schirmer books. pp.265 - 286
2. D. Lorrain. A panoply of stochastic cannons. In C. Roads, ed. 1989. Music machine . Cambridge, Massachusetts: MIT press, pp. 351 - 379.

## Examples

Here is an example of the pcauchy opcode. It uses the file *pcauchy.csd* [examples/pcauchy.csd].

### Example 607. Example of the pcauchy opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pchbend

pchbend — Get the current pitch-bend value for this channel.

## Description

Get the current pitch-bend value for this channel.

## Syntax

```
ibend pchbend [imin] [, imax]
```

```
kbend pchbend [imin] [, imax]
```

## Initialization

*imin, imax* (optional) -- set minimum and maximum limits on values obtained

## Performance

Get the current pitch-bend value for this channel. Note that this access to pitch-bend data is independent of the MIDI pitch, enabling the value here to be used for any arbitrary purpose.

## Examples

Here is an example of the pchbend opcode. It uses the file *pchbend.csd* [examples/pchbend.csd].

### Example 608. Example of the pchbend opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pchmidi

pchmidi — Get the note number of the current MIDI event, expressed in pitch-class units.

## Description

Get the note number of the current MIDI event, expressed in pitch-class units.

## Syntax

```
ipch pchmidi
```

## Performance

Get the note number of the current MIDI event, expressed in pitch-class units for local processing.

### pchmidi vs. pchmidinn

The *pchmidi* opcode only produces meaningful results in a Midi-activated note (either real-time or from a Midi score with the -F flag). With *pchmidi*, the Midi note number value is taken from the Midi event that is internally associated with the instrument instance. On the other hand, the *pchmidinn* opcode may be used in any Csound instrument instance whether it is activated from a Midi event, score event, line event, or from another instrument. The input value for *pchmidinn* might for example come from a p-field in a textual score or it may have been retrieved from the real-time Midi event that activated the current note using the *notnum* opcode.

## Examples

Here is an example of the pchmidi opcode. It uses the file *pchmidi.csd* [examples/pchmidi.csd].

### Example 609. Example of the pchmidi opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# pchmidib

pchmidib — Get the note number of the current MIDI event and modify it by the current pitch-bend value, express it in pitch-class units.

## Description

Get the note number of the current MIDI event and modify it by the current pitch-bend value, express it in pitch-class units.

## Syntax

```
ipch pchmidib [irange]
```

```
kpch pchmidib [irange]
```

## Initialization

*irange* (optional) -- the pitch bend range in semitones

## Performance

Get the note number of the current MIDI event, modify it by the current pitch-bend value, and express the result in pitch-class units. Available as an i-time value or as a continuous k-rate value.

## Examples

Here is an example of the pchmidib opcode. It uses the file *pchmidib.csd* [examples/pchmidib.csd].

### Example 610. Example of the pchmidib pchmidib.

# pchmidinn

pchmidinn — Converts a Midi note number value to octave point pitch-class units.

## Description

Converts a Midi note number value to octave point pitch-class units.

## Syntax

**pchmidinn** (MidiNoteNumber) (init- or control-rate args only)

where the argument within the parentheses may be a further expression.

## Performance

*pchmidinn* is a function that takes an i-rate or k-rate value representing a Midi note number and returns the equivalent pitch value in Csound's octave point pitch-class format. This conversion assumes that Middle C (8.00 in *pch*) is Midi note number 60. Midi note number values are typically integers in the range from 0 to 127 but fractional values or values outside of this range will be interpreted consistently.

### pchmidinn vs. pchmidi

The *pchmidinn* opcode may be used in any Csound instrument instance whether it is activated from a Midi event, score event, line event, or from another instrument. The input value for *pchmidinn* might for example come from a p-field in a textual score or it may have been retrieved from the real-time Midi event that activated the current note using the *notnum* opcode. You must specify an i-rate or k-rate expression for the Midi note number that is to be converted. On the other hand, the *pchmidi* opcode only produces meaningful results in a Midi-activated note (either real-time or from a Midi score with the -F flag). With *pchmidi*, the Midi note number value is taken from the Midi event associated with the instrument instance, and no location or expression for this value may be specified.

*pchmidinn* and its related opcodes are really *value converters* with a special function of manipulating pitch data.

Data concerning pitch and frequency can exist in any of the following forms:

**Table 19. Pitch and Frequency Values**

| Name                              | Abbreviation |
|-----------------------------------|--------------|
| octave point pitch-class (8ve.pc) | pch          |
| octave point decimal              | oct          |
| cycles per second                 | cps          |
| Midi note number (0-127)          | midinn       |

The first two forms consist of a whole number, representing octave registration, followed by a specially interpreted fractional part. For *pch*, the fraction is read as two decimal digits representing the 12 equal-

tempered pitch classes from .00 for C to .11 for B. For *oct*, the fraction is interpreted as a true decimal fractional part of an octave. The two fractional forms are thus related by the factor 100/12. In both forms, the fraction is preceded by a whole number octave index such that 8.00 represents Middle C, 9.00 the C above, etc. Midi note number values range between 0 and 127 (inclusively) with 60 representing Middle C, and are usually whole numbers. Thus A440 can be represented alternatively by 440 (*cps*), 69 (*midinn*), 8.09 (*pch*), or 8.75 (*oct*). Microtonal divisions of the *pch* semitone can be encoded by using more than two decimal places.

The mnemonics of the pitch conversion units are derived from morphemes of the forms involved, the second morpheme describing the source and the first morpheme the object (result). Thus *cpspch*(8.09) will convert the pitch argument 8.09 to its *cps* (or Hertz) equivalent, giving the value of 440. Since the argument is constant over the duration of the note, this conversion will take place at i-time, before any samples for the current note are produced.

By contrast, the conversion *cpsoct*(8.75 + *k1*) which gives the value of A440 transposed by the octave interval *k1*. The calculation will be repeated every *k*-period since that is the rate at which *k1* varies.

## Note

The conversion from *pch*, *oct*, or *midinn* into *cps* is not a linear operation but involves an exponential process that could be time-consuming when executed repeatedly. Csound now uses a built-in table lookup to do this efficiently, even at audio rates. Because the table index is truncated without interpolation, pitch resolution when using one of these opcodes is limited to 8192 discrete and equal divisions of the octave, and some pitches of the standard 12-tone equally-tempered scale are very slightly mistuned (by at most 0.15 cents).

# Examples

Here is an example of the *pchmidinn* opcode. It uses the file *cpsmidinn.csd* [examples/cpsmidinn.csd].

### Example 611. Example of the *pchmidinn* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pchoct

pchoct — Converts an octave-point-decimal value to pitch-class.

## Description

Converts an octave-point-decimal value to pitch-class.

## Syntax

**pchoct** (oct) (init- or control-rate args only)

where the argument within the parentheses may be a further expression.

## Performance

*pchoct* and its related opcodes are really *value converters* with a special function of manipulating pitch data.

Data concerning pitch and frequency can exist in any of the following forms:

**Table 20. Pitch and Frequency Values**

| Name                              | Abbreviation |
|-----------------------------------|--------------|
| octave point pitch-class (8ve.pc) | pch          |
| octave point decimal              | oct          |
| cycles per second                 | cps          |
| Midi note number (0-127)          | midinn       |

The first two forms consist of a whole number, representing octave registration, followed by a specially interpreted fractional part. For *pch*, the fraction is read as two decimal digits representing the 12 equal-tempered pitch classes from .00 for C to .11 for B. For *oct*, the fraction is interpreted as a true decimal fractional part of an octave. The two fractional forms are thus related by the factor 100/12. In both forms, the fraction is preceded by a whole number octave index such that 8.00 represents Middle C, 9.00 the C above, etc. Midi note number values range between 0 and 127 (inclusively) with 60 representing Middle C, and are usually whole numbers. Thus A440 can be represented alternatively by 440 (*cps*), 69 (*midinn*), 8.09 (*pch*), or 8.75 (*oct*). Microtonal divisions of the *pch* semitone can be encoded by using more than two decimal places.

The mnemonics of the pitch conversion units are derived from morphemes of the forms involved, the second morpheme describing the source and the first morpheme the object (result). Thus *cspch*(8.09) will convert the pitch argument 8.09 to its *cps* (or Hertz) equivalent, giving the value of 440. Since the argument is constant over the duration of the note, this conversion will take place at i-time, before any samples for the current note are produced.

By contrast, the conversion *csoct*(8.75 + *k1*) which gives the value of A440 transposed by the octave interval *k1*. The calculation will be repeated every k-period since that is the rate at which *k1* varies.

## Note

The conversion from *pch*, *oct*, or *midinn* into *cps* is not a linear operation but involves an exponential process that could be time-consuming when executed repeatedly. Csound now uses a built-in table lookup to do this efficiently, even at audio rates. Because the table index is truncated without interpolation, pitch resolution when using one of these opcodes is limited to 8192 discrete and equal divisions of the octave, and some pitches of the standard 12-tone equally-tempered scale are very slightly mistuned (by at most 0.15 cents).

## Examples

Here is an example of the *pchoct* opcode. It uses the file *pchoct.csd* [examples/pchoct.csd].

### Example 612. Example of the *pchoct* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>

# pconvolve

convolve — Convolution based on a uniformly partitioned overlap-save algorithm

## Description

Convolution based on a uniformly partitioned overlap-save algorithm. Compared to the *convolve* opcode, *pconvolve* has these benefits:

- small delay
- possible to run in real-time for shorter impulse files
- no pre-process analysis pass
- can often render faster than *convolve*

## Syntax

```
ar1 [, ar2] [, ar3] [, ar4] pconvolve ain, ifilcod [, ipartitionsiz, ichannel]
```

## Initialization

*ofilcod* -- integer or character-string denoting an impulse response soundfile. Multichannel files are supported, the file must have the same sample-rate as the orc. [Note: *cval* files cannot be used!] Keep in mind that longer files require more calculation time [and probably larger partition sizes and more latency]. At current processor speeds, files longer than a few seconds may not render in real-time.

*ipartitionsiz* (optional, defaults to the output buffersize [-b]) -- the size in samples of each partition of the impulse file. This is the parameter that needs tweaking for best performance depending on the impulse file size. Generally, a small size means smaller latency but more computation time. If you specify a value that is not a power-of-2 the opcode will find the next power-of-2 greater and use that as the actual partition size.

*ichannel* (optional) -- which channel to use from the impulse response data file.

## Performance

*ain* -- input audio signal.

The overall latency of the opcode can be calculated as such [assuming *ipartitionsiz* is a power of 2]

```
i latency = (ksmps < ipartitionsiz ? ipartitionsiz + ksmpls : ipartitionsiz)/sr
```

## Examples

Instrument 1 shows an example of real-time convolution.

Instrument 2 shows how to do file-based convolution with a 'look ahead' method to remove all delay.

## NOTE

You can download impulse response files from noisevault.com or replace the filenames with your own impulse files.

Here is an example of the pconvolve opcode. It uses the file *pconvolve.csd* [examples/pconvolve.csd].

### Example 613. Example of the pconvolve opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pcount

pcount — Returns the number of pfields belonging to a note event.

## Description

*pcount* returns the number of pfields belonging to a note event.

## Syntax

```
icount pcount
```

## Initialization

*icount* - stores the number of pfields for the current note event.

### Note

Note that the reported number of pfields is not necessarily what's explicitly written in the score, but the pfields available to the instrument through mechanisms like *pfield carry*.

## Examples

Here is an example of the pcount opcode. It uses the file *pcount.csd* [examples/pcount.csd].

### Example 614. Example of the pcount opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pdclip

`pdclip` — Performs linear clipping on an audio signal or a phasor.

## Description

The `pdclip` opcode allows a percentage of the input range of a signal to be clipped to fullscale. It is similar to simply multiplying the signal and limiting the range of the result, but `pdclip` allows you to think about how much of the signal range is being distorted instead of the scalar factor and has a offset parameter for assymetric clipping of the signal range. `pdclip` is also useful for remapping phasors for phase distortion synthesis.

## Syntax

```
aout pdclip ain, kWidth, kCenter [, ibipolar [, ifullscale]]
```

## Initialization

`ibipolar` -- an optional parameter specifying either unipolar (0) or bipolar (1) mode. Defaults to unipolar mode.

`ifullscale` -- an optional parameter specifying the range of input and output values. The maximum will be `ifullscale`. The minimum depends on the mode of operation: zero for unipolar or `-ifullscale` for bipolar. Defaults to 1.0 -- you should set this parameter to the maximum expected input value.

## Performance

`ain` -- the input signal to be clipped.

`aout` -- the output signal.

`kWidth` -- the percentage of the signal range that is clipped (must be between 0 and 1).

`kCenter` -- an offset for shifting the unclipped window of the signal higher or lower in the range (essentially a DC offset). Values should be in the range [-1, 1] with a value of zero representing no shift (regardless of whether bipolar or unipolar mode is used).

The `pdclip` opcode performs linear clipping on the input signal `ain`. `kWidth` specifies the percentage of the signal range that is clipped. The rest of the input range is mapped linearly from zero to `ifullscale` in unipolar mode and from `-ifullscale` to `ifullscale` in bipolar mode. When `kCenter` is zero, equal amounts of the top and bottom of the signal range are clipped. A negative value shifts the unclipped range more towards the bottom of the input range and a positive value shifts it more towards the top. `ibipolar` should be 1 for bipolar operation and 0 for unipolar mode. The default is unipolar mode (`ibipolar = 0`). `ifullscale` sets the maximum amplitude of the input and output signals (defaults to 1.0).

This amounts to waveshaping the input with the following transfer function (normalized to `ifullscale=1.0` in bipolar mode):

1| \_\_\_\_\_ x-axis is input range, y-axis is output  
| /  
| / width of clipped region is  $2*kWidth$

```
-1    /|   1    width of unclipped region is 2*(1 - kWidth)
-----  kCenter shifts the unclipped region
      /|   left or right (up to kWidth)
      /|
      /|
----- |-1
```

Bipolar mode can be used for direct, linear distortion of an audio signal. Alternatively, unipolar mode is useful for modifying the output of a phasor before it is used to index a function table, effectively making this a phase distortion technique.

# pdhalf

`pdhalf` — Distorts a phasor for reading the two halves of a table at different rates.

## Description

The `pdhalf` opcode is designed to emulate the "classic" phase distortion synthesis method of the Casio CZ-series of synthesizers from the mid-1980's. This technique reads the first and second halves of a function table at different rates in order to warp the waveform. For example, `pdhalf` can smoothly transform a sine wave into something approximating the shape of a saw wave.

## Syntax

```
aout pdhalf ain, kShapeAmount [, ibipolar [, ifullsclae]]
```

## Initialization

*ibipolar* -- an optional parameter specifying either unipolar (0) or bipolar (1) mode. Defaults to unipolar mode.

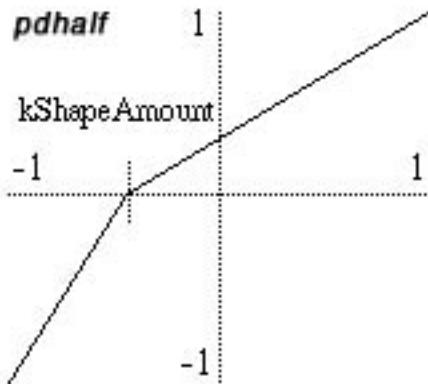

*ifullsclae* -- an optional parameter specifying the range of input and output values. The maximum will be *ifullsclae*. The minimum depends on the mode of operation: zero for unipolar or *-ifullsclae* for bipolar. Defaults to 1.0 -- you should set this parameter to the maximum expected input value.

## Performance

*ain* -- the input signal to be distorted.

*aout* -- the output signal.

*kShapeAmount* -- the amount of distortion applied to the input. Must be between negative one and one (-1 to 1). An amount of zero means no distortion.

Transfer function created by `pdhalf` and a negative *kShapeAmount*.

The `pdhalf` opcode calculates a transfer function that is composed of two linear segments (see the graph). These segments meet at a "pivot point" which always lies on the same horizontal axis. (In unipolar mode, the axis is  $y = 0.5$ , and for bipolar mode it is the  $x$  axis). The *kShapeAmount* parameter spe-

cifies where on the horizontal axis this point falls. When *kShapeAmount* is zero, the pivot point is in the middle of the input range, forming a straight line for the transfer function and thus causing no change in the input signal. As *kShapeAmount* changes from zero (0) to negative one (-1), the pivot point moves towards the left side of the graph, producing a phase distortion pattern like the Casio CZ's "sawtooth waveform". As it changes from zero (0) to positive one (1), the pivot point moves toward the right, producing an inverted pattern.

If the input to *pdhalf* is a phasor and the output is used to index a table, values for *kShapeAmount* that are less than zero will cause the first half of the table to be read more quickly than the second half. The reverse is true for values of *kShapeAmount* greater than zero. The rates at which the halves are read are calculated so that the frequency of the phasor is unchanged. Thus, this method of phase distortion can only produce higher partials in a harmonic series. It cannot produce inharmonic sidebands in the way that frequency modulation does.

*pdhalf* can work in either unipolar or bipolar modes. Unipolar mode is appropriate for signals like phasors that range between zero and some maximum value (selectable with *ifullscale*). Bipolar mode is appropriate for signals that range above and below zero by roughly equal amounts such as most audio signals. Applying *pdhalf* directly to an audio signal in this way results in a crude but adjustable sort of waveshaping/distortion.

A typical example of the use of *pdhalf* is

```
aphase    phasor      ifreq
apd       pdhalf      aphase, kamount
aout      tablei     apd, 1, 1
```

## Examples

Here is an example of the *pdhalf* opcode. It uses the file *pdhalf.csd* [examples/pdhalf.csd].

# pdhalfy

**pdhalfy** — Distorts a phasor for reading two unequal portions of a table in equal periods.

## Description

The *pdhalfy* opcode is a variation on the phase distortion synthesis method of the *pdhalf* opcode. It is useful for distorting a phasor in order to read two unequal portions of a table in the same number of samples.

## Syntax

```
aout pdhalfy ain, kShapeAmount [, ibipolar [, ifullsclae]]
```

## Initialization

*ibipolar* -- an optional parameter specifying either unipolar (0) or bipolar (1) mode. Defaults to unipolar mode.

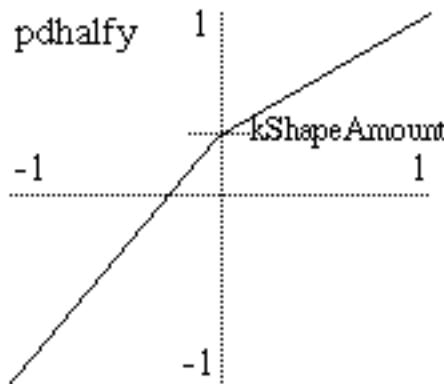

*ifullsclae* -- an optional parameter specifying the range of input and output values. The maximum will be *ifullsclae*. The minimum depends on the mode of operation: zero for unipolar or *-ifullsclae* for bipolar. Defaults to 1.0 -- you should set this parameter to the maximum expected input value.

## Performance

*ain* -- the input signal to be distorted.

*aout* -- the output signal.

*kShapeAmount* -- the amount of distortion applied to the input. Must be between negative one and one (-1 to 1). An amount of zero means no distortion.

Transfer function created by pdhalfy and a negative kShapeAmount.

The *pdhalfy* opcode calculates a transfer function that is composed of two linear segments (see the graph). These segments meet at a "pivot point" which always lies on the same vertical axis. (In unipolar mode, the axis is x = 0.5, and for bipolar mode it is the y axis). So, *pdhalfy* is a variation of the *pdhalf*

opcode that places the pivot point of the phase distortion pattern on a vertical axis instead of a horizontal axis.

The *kShapeAmount* parameter specifies where on the vertical axis this point falls. When *kShapeAmount* is zero, the pivot point is in the middle of the output range, forming a straight line for the transfer function and thus causing no change in the input signal. As *kShapeAmount* changes from zero (0) to negative one (-1), the pivot point downward towards the bottom of the graph. As it changes from zero (0) to positive one (1), the pivot point moves upward, producing an inverted pattern.

If the input to *pdhalfy* is a phasor and the output is used to index a table, the use of *pdhalfy* will divide the table into two segments of different sizes with each segment being mapped to half of the oscillator period. Values for *kShapeAmount* that are less than zero will cause less than half of the table to be read in the first half of the period of oscillation. The rest of the table will be read in the second half of the period. The reverse is true for values of *kShapeAmount* greater than zero. Note that the frequency of the phasor is always unchanged. Thus, this method of phase distortion can only produce higher partials in a harmonic series. It cannot produce inharmonic sidebands in the way that frequency modulation does. *pdhalfy* tends to have a milder quality to its distortion than *pdhalf*.

*pdhalfy* can work in either unipolar or bipolar modes. Unipolar mode is appropriate for signals like phasors that range between zero and some maximum value (selectable with *ifullscale*). Bipolar mode is appropriate for signals that range above and below zero by roughly equal amounts such as most audio signals. Applying *pdhalfy* directly to an audio signal in this way results in a crude but adjustable sort of waveshaping/distortion.

A typical example of the use of *pdhalfy* is

```
aphase    phasor      ifreq

# peak

`peak` — Maintains the output equal to the highest absolute value received.

## Description

These opcodes maintain the output k-rate variable as the peak absolute level so far received.

## Syntax

```
kres peak asig  
  
kres peak ksig
```

## Performance

*kres* -- Output equal to the highest absolute value received so far. This is effectively an input to the opcode as well, since it reads *kres* in order to decide whether to write something higher into it.

*ksig* -- k-rate input signal.

*asig* -- a-rate input signal.

## Examples

Here is an example of the `peak` opcode. It uses the file `peak.csd` [examples/peak.csd], and `beats.wav` [examples/beats.wav].

### Example 618. Example of the peak opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pgmassign

pgmassign — Assigns an instrument number to a specified MIDI program.

## Description

Assigns an instrument number to a specified (or all) MIDI program(s).

By default, the instrument is the same as the program number. If the selected instrument is zero or negative or does not exist, the program change is ignored. This opcode is normally used in the orchestra header. Although, like *massign*, it also works in instruments.

## Syntax

```
pgmassign ipgm, inst[, ichn]  
  
pgmassign ipgm, "insname"[, ichn]
```

## Initialization

*ipgm* -- MIDI program number (1 to 128). A value of zero selects all programs.

*inst* -- instrument number. If set to zero, or negative, MIDI program changes to *ipgm* are ignored. Currently, assignment to an instrument that does not exist has the same effect. This may be changed in a later release to print an error message.

“*insname*” -- A string (in double-quotes) representing a named instrument.

“*ichn*” (optional, defaults to zero) -- channel number. If zero, program changes are assigned on all channels.

You can disable the turning on of any instruments by using the following in the header:

```
massign 0, 0  
pgmassign 0, 0
```

## Examples

Here is an example of the pgmassign opcode. It uses the file *pgmassign.csd* [examples/pgmassign.csd].

### Example 619. Example of the pgmassign opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# phaser1

phaser1 — First-order allpass filters arranged in a series.

## Description

An implementation of *iord* number of first-order allpass filters in series.

## Syntax

```
ares phaser1 asig, kfreq, kord, kfeedback [, iskip]
```

## Initialization

*iskip* (optional, default=0) -- used to control initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*kfreq* -- frequency (in Hz) of the filter(s). This is the frequency at which each filter in the series shifts its input by 90 degrees.

*kord* -- the number of allpass stages in series. These are first-order filters and can range from 1 to 4999.

### Note

Although *kord* is listed as k-rate, it is in fact accessed only at init-time. So if you are using a k-rate argument, it must be assigned with *init*.

*kfeedback* -- amount of the output which is fed back into the input of the allpass chain. With larger amounts of feedback, more prominent notches appear in the spectrum of the output. *kfeedback* must be between -1 and +1. for stability.

*phaser1* implements *iord* number of first-order allpass sections, serially connected, all sharing the same coefficient. Each allpass section can be represented by the following difference equation:

$$y(n) = C * x(n) + x(n-1) - C * y(n-1)$$

where *x(n)* is the input, *x(n-1)* is the previous input, *y(n)* is the output, *y(n-1)* is the previous output, and *C* is a coefficient which is calculated from the value of *kfreq*, using the bilinear z-transform.

By slowly varying *kfreq*, and mixing the output of the allpass chain with the input, the classic "phase shifter" effect is created, with notches moving up and down in frequency. This works best with *iord* between 4 and 16. When the input to the allpass chain is mixed with the output, 1 notch is generated for every 2 allpass stages, so that with *iord* = 6, there will be 3 notches in the output. With higher values for *iord*, modulating *kfreq* will result in a form of nonlinear pitch modulation.

# Examples

Here is an example of the phaser1 opcode. It uses the file *phaser1.csd* [examples/phaser1.csd].

## Technical History

A general description of the differences between flanging and phasing can be found in Hartmann [1]. An early implementation of first-order allpass filters connected in series can be found in Beigel [2], where the bilinear z-transform is used for determining the phase shift frequency of each stage. Cronin [3] presents a similar implementation for a four-stage phase shifting network. Chamberlin [4] and Smith [5] both discuss using second-order allpass sections for greater control over notch depth, width, and frequency.

# phaser2

phaser2 — Second-order allpass filters arranged in a series.

## Description

An implementation of *iord* number of second-order allpass filters in series.

## Syntax

```
ares phaser2 asig, kfreq, kq, kord, kmode, ksep, kfeedback
```

## Performance

*kfreq* -- frequency (in Hz) of the filter(s). This is the center frequency of the notch of the first allpass filter in the series. This frequency is used as the base frequency from which the frequencies of the other notches are derived.

*kq* -- Q of each notch. Higher Q values result in narrow notches. A Q between 0.5 and 1 results in the strongest "phasing" effect, but higher Q values can be used for special effects.

*kord* -- the number of allpass stages in series. These are second-order filters, and *iord* can range from 1 to 2499. With higher orders, the computation time increases.

*kfeedback* -- amount of the output which is fed back into the input of the allpass chain. With larger amounts of feedback, more prominent notches appear in the spectrum of the output. *kfeedback* must be between -1 and +1, for stability.

*kmode* -- used in calculation of notch frequencies.

### Note

Although *kord* and *kmode* are listed as k-rate, they are in fact accessed only at init-time. So if you are using k-rate arguments, they must be assigned with *init*.

*ksep* -- scaling factor used, in conjunction with *imode*, to determine the frequencies of the additional notches in the output spectrum.

*phaser2* implements *iord* number of second-order allpass sections, connected in series. The use of second-order allpass sections allows for the precise placement of the frequency, width, and depth of notches in the frequency spectrum. *iord* is used to directly determine the number of notches in the spectrum; e.g. for *iord* = 6, there will be 6 notches in the output spectrum.

There are two possible modes for determining the notch frequencies. When *imode* = 1, the notch frequencies are determined by the following function:

$$\text{frequency of notch } N = \text{kbf} + (\text{ksep} * \text{kbf} * N - 1)$$

For example, with *imode* = 1 and *ksep* = 1, the notches will be in harmonic relationship with the notch frequency determined by *kfreq* (i.e. if there are 8 notches, with the first at 100 Hz, the next notches will be at 200, 300, 400, 500, 600, 700, and 800 Hz). This is useful for generating a "comb filtering" effect,

with the number of notches determined by *iord*. Different values of *ksep* allow for inharmonic notch frequencies and other special effects. *ksep* can be swept to create an expansion or contraction of the notch frequencies. A useful visual analogy for the effect of sweeping *ksep* would be the bellows of an accordio on as it is being played - the notches will be separated, then compressed together, as *ksep* changes.

When *imode* = 2, the subsequent notches are powers of the input parameter *ksep* times the initial notch frequency specified by *kfreq*. This can be used to set the notch frequencies to octaves and other musical intervals. For example, the following lines will generate 8 notches in the output spectrum, with the notches spaced at octaves of *kfreq*:

```
aphs  phaser2  ain, kfreq, 0.5, 8, 2, 2, 0  
aout  =      ain + aphs
```

When *imode* = 2, the value of *ksep* must be greater than 0. *ksep* can be swept to create a compression and expansion of notch frequencies (with more dramatic effects than when *imode* = 1).

## Examples

Here is an example of the phaser2 opcode. It uses the file *phaser2.csd* [examples/phaser2.csd].

# phasor

phasor — Produce a normalized moving phase value.

## Description

Produce a normalized moving phase value.

## Syntax

```
ares phasor xcps [, iphs]
```

```
kres phasor kcps [, iphs]
```

## Initialization

*iphs* (optional) -- initial phase, expressed as a fraction of a cycle (0 to 1). A negative value will cause phase initialization to be skipped. The default value is zero.

## Performance

An internal phase is successively accumulated in accordance with the *kcps* or *xcps* frequency to produce a moving phase value, normalized to lie in the range  $0 \leq \text{phs} < 1$ .

When used as the index to a *table* unit, this phase (multiplied by the desired function table length) will cause it to behave like an oscillator.

Note that *phasor* is a special kind of integrator, accumulating phase increments that represent frequency settings.

## Examples

Here is an example of the phasor opcode. It uses the file *phasor.csd* [examples/phasor.csd].

### Example 624. Example of the phasor opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-o dac      ;;;realtime audio out
;-iadc     ;;;uncomment -iadc if real audio input is needed too
; For Non-realtime output leave only the line below:
; -o phasor.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1
```

```

The *Table Access* opcodes like: *table*, *tablei*, *table3* and *tab*.

Also: *phasorbnk*.

# phasorbnk

phasorbnk — Produce an arbitrary number of normalized moving phase values.

## Description

Produce an arbitrary number of normalized moving phase values, accessable by an index.

## Syntax

```
ares phasorbnk xcps, kndx, icnt [, iphs]  
  
kres phasorbnk kcps, kndx, icnt [, iphs]
```

## Initialization

*icnt* -- maximum number of phasors to be used.

*iphs* -- initial phase, expressed as a fraction of a cycle (0 to 1). If -1 initialization is skipped. If *iphs*>1 each phasor will be initialized with a random value.

## Performance

*kndx* -- index value to access individual phasors

For each independent phasor, an internal phase is successively accumulated in accordance with the *kcps* or *xcps* frequency to produce a moving phase value, normalized to lie in the range  $0 \leq \text{phs} < 1$ . Each individual phasor is accessed by index *kndx*.

This phasor bank can be used inside a k-rate loop to generate multiple independent voices, or together with the *adsynt* opcode to change parameters in the tables used by *adsynt*.

## Examples

Here is an example of the phasorbnk opcode. It uses the file *phasorbnk.csd* [examples/phasorbnk.csd].

### Example 625. Example of the phasorbnk opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# phs

phs — Obtains the phases of a complex-number array

## Description

This opcode returns the phases of a complex-number array, as a real-valued array with half the size of its input plus one. The reason for the extra point is to keep the array size equivalent to the output of the mags opcode (which is often used alongside this one).

## Syntax

```
kout[] phs kin[]
```

## Performance

*kout[]* -- output array containing the phases. It will be created if it does not exist.

*kin[]* -- input array containing the complex-valued real-imaginary input.

## Examples

Here is an example of the phs opcode. It uses the file *phs.csd* [examples/phs.csd].

### Example 626. Example of the phs opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pindex

`pindex` — Returns the value of a specified pfield.

## Description

`pindex` returns the value of a specified pfield.

## Syntax

```
ivalue pindex ipfieldIndex
```

## Initialization

*ipfieldIndex* - pfield number to query.

*ivalue* - value of the pfield.

## Examples

Here is an example of the `pindex` opcode. It uses the file `pindex.csd` [examples/pindex.csd].

### Example 627. Example of the pindex opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# pinker

pinker — Generates pink noise.

## Description

Generates pink noise (-3dB/oct response) by the *New Shade of Pink* algorithm of Stefan Stenzel.

## Syntax

```
ares pinker
```

## Performance

*pinker* generates pink noise (i.e., noise with equal energy in each octave), by the algorithm of Stefan Stenzel. For details of the algorithm look at <http://stenzel.waldorfmusic.de/post/pink/>.

## Examples

Here is an example of the *pinker* opcode. It uses the file *pinker.csd* [examples/pinker.csd].

### Example 629. Example of the pinker opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pinkish

`pinkish` — Generates approximate pink noise.

## Description

Generates approximate pink noise (-3dB/oct response) by one of two different methods:

- a multirate noise generator after Moore, coded by Martin Gardner
- a filter bank designed by Paul Kellet

## Syntax

```
ares pinkish xin [, imethod] [, inumbands] [, iseeds] [, iskip]
```

## Initialization

*imethod* (optional, default=0) -- selects filter method:

- 0 = Gardner method (default).
- 1 = Kellet filter bank.
- 2 = A somewhat faster filter bank by Kellet, with less accurate response.

*inumbands* (optional) -- only effective with Gardner method. The number of noise bands to generate. Maximum is 32, minimum is 4. Higher levels give smoother spectrum, but above 20 bands there will be almost DC-like slow fluctuations. Default value is 20.

*iseed* (optional, default=0) -- only effective with Gardner method. If non-zero, seeds the random generator. If zero, the generator will be seeded from current time. Default is 0.

*iskip* (optional, default=0) -- if non-zero, skip (re)initialization of internal state (useful for tied notes). Default is 0.

## Performance

*xin* -- for Gardner method: k- or a-rate amplitude. For Kellet filters: normally a-rate uniform random noise from rand (31-bit) or unirand, but can be any a-rate signal. The output peak value varies widely ( $\pm 15\%$ ) even over long runs, and will usually be well below the input amplitude. Peak values may also occasionally overshoot input amplitude or noise.

*pinkish* attempts to generate pink noise (i.e., noise with equal energy in each octave), by one of two different methods.

The first method, by Moore & Gardner, adds several (up to 32) signals of white noise, generated at octave rates (sr, sr/2, sr/4 etc). It obtains pseudo-random values from an internal 32-bit generator. This random generator is local to each opcode instance and seedable (similar to *rand*).

The second method is a lowpass filter with a response approximating -3dB/oct. If the input is uniform white noise, it outputs pink noise. Any signal may be used as input for this method. The high quality filter is slower, but has less ripple and a slightly wider operating frequency range than less computationally intense versions. With the Kellet filters, seeding is not used.

The Gardner method output has some frequency response anomalies in the low-mid and high-mid frequency ranges. More low-frequency energy can be generated by increasing the number of bands. It is also a bit faster. The refined Kellet filter has very smooth spectrum, but a more limited effective range. The level increases slightly at the high end of the spectrum.

## Examples

Here is an example of the pinkish opcode. It uses the file *pinkish.csd* [examples/pinkish.csd].

### Example 630. Example of the pinkish opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

University of Bath/Codemist Ltd.  
Bath, UK  
May 2000

New in Csound Version 4.07

Adapted for Csound by Rasmus Ekman

The noise bands method is due to F. R. Moore (or R. F. Voss), and was presented by Martin Gardner in an oft-cited article in Scientific American. The present version was coded by Phil Burk as the result of discussion on the music-dsp mailing list, with significant optimizations suggested by James McCartney.

The filter bank was designed by Paul Kellet, posted to the music-dsp mailing list.

The whole pink noise discussion was collected on a HTML page by Robin Whittle, which is currently available at <http://www.firstpr.com.au/dsp/pink-noise/>.

Added notes by Rasmus Ekman on September 2002.

# **pitch**

`pitch` — Tracks the pitch of a signal.

## **Description**

Using the same techniques as *spectrum* and *specptrk*, pitch tracks the pitch of the signal in octave point decimal form, and amplitude in dB.

## **Syntax**

```
koct, kamp pitch asig, iupdte, ilo, ihi, idbthresh [, ifrqs] [, iconf] \
[, istrt] [, iocts] [, iq] [, inptls] [, irolloff] [, iskip]
```

## **Initialization**

*iupdte* -- length of period, in seconds, that outputs are updated

*ilo, ihi* -- range in which pitch is detected, expressed in octave point decimal

*idbthresh* -- amplitude, expressed in decibels, necessary for the pitch to be detected. Once started it continues until it is 6 dB down.

*ifrqs* (optional) -- number of divisons of an octave. Default is 12 and is limited to 120.

*iconf* (optional) -- the number of conformations needed for an octave jump. Default is 10.

*istrt* (optional) -- starting pitch for tracker. Default value is  $(ilo + ihi)/2$ .

*iocts* (optional) -- number of octave decimations in spectrum. Default is 6.

*iq* (optional) -- Q of analysis filters. Default is 10.

*inptls* (optional) -- number of harmonics, used in matching. Computation time increases with the number of harmonics. Default is 4.

*iroloff* (optional) -- amplitude rolloff for the set of filters expressed as fraction per octave. Values must be positive. Default is 0.6.

*iskip* (optional) -- if non-zero, skips initialization. Default is 0.

## **Performance**

*koct* -- The pitch output, given in the octave point decimal format.

*kamp* -- The amplitude output.

*pitch* analyzes the input signal, *asig*, to give a pitch/amplitude pair of outputs, for the strongest frequency in the signal. The value is updated every *iupdte* seconds.

The number of partials and rolloff fraction can effect the pitch tracking, so some experimentation may be necessary. Suggested values are 4 or 5 harmonics, with rolloff 0.6, up to 10 or 12 harmonics with rolloff 0.75 for complex timbres, with a weak fundamental.

# Examples

Here is an example of the pitch opcode. It uses the file *pitch.csd* [examples/pitch.csd].

## Example 631. Example of the pitch opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# **pitchamdf**

**pitchamdf** — Follows the pitch of a signal based on the AMDF method.

## **Description**

Follows the pitch of a signal based on the AMDF method (Average Magnitude Difference Function). Outputs pitch and amplitude tracking signals. The method is quite fast and should run in realtime. This technique usually works best for monophonic signals.

## **Syntax**

```
kcps, krms pitchamdf asig, imincps, imaxcps [, icps] [, imedi] \
[, idowns] [, iexcps] [, irrmsmedi]
```

## **Initialization**

*imincps* -- estimated minimum frequency (expressed in Hz) present in the signal

*imaxcps* -- estimated maximum frequency present in the signal

*icps* (optional, default=0) -- estimated initial frequency of the signal. If 0, *icps* = (*imincps*+*imaxcps*) / 2. The default is 0.

*imedi* (optional, default=1) -- size of median filter applied to the output *k cps*. The size of the filter will be *imedi*\*2+1. If 0, no median filtering will be applied. The default is 1.

*idowns* (optional, default=1) -- downsampling factor for *asig*. Must be an integer. A factor of *idowns* > 1 results in faster performance, but may result in worse pitch detection. Useful range is 1 - 4. The default is 1.

*iexcps* (optional, default=0) -- how frequently pitch analysis is executed, expressed in Hz. If 0, *iexcps* is set to *imincps*. This is usually reasonable, but experimentation with other values may lead to better results. Default is 0.

*irmsmedi* (optional, default=0) -- size of median filter applied to the output *krms*. The size of the filter will be *irmsmedi*\*2+1. If 0, no median filtering will be applied. The default is 0.

## **Performance**

*k cps* -- pitch tracking output

*krms* -- amplitude tracking output

*pitchamdf* usually works best for monophonic signals, and is quite reliable if appropriate initial values are chosen. Setting *imincps* and *imaxcps* as narrow as possible to the range of the signal's pitch, results in better detection and performance.

Because this process can only detect pitch after an initial delay, setting *icps* close to the signal's real initial pitch prevents spurious data at the beginning.

The median filter prevents *k cps* from jumping. Experiment to determine the optimum value for *imedi* for a given signal.

Other initial values can usually be left at the default settings. Lowpass filtering of *asig* before passing it to *pitchamdf*, can improve performance, especially with complex waveforms.

## Examples

Here is an example of the *pitchamdf* opcode. It uses the file *pitchamdf.csd* [examples/pitchamdf.csd].

### Example 632. Example of the *pitchamdf* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# planet

`planet` — Simulates a planet orbiting in a binary star system.

## Description

`planet` simulates a planet orbiting in a binary star system. The outputs are the x, y and z coordinates of the orbiting planet. It is possible for the planet to achieve escape velocity by a close encounter with a star. This makes this system somewhat unstable.

## Syntax

```
ax, ay, az planet kmass1, kmass2, ksep, ix, iy, iz, ivx, ivy, ivz, idelta \
[, ifriction] [, iskip]
```

## Initialization

*ix, iy, iz* -- the initial x, y and z coordinates of the planet

*ivx, ivy, ivz* -- the initial velocity vector components for the planet.

*idelta* -- the step size used to approximate the differential equation.

*ifriction* (optional, default=0) -- a value for friction, which can be used to keep the system from blowing up

*iskip* (optional, default=0) -- if non zero skip the initialisation of the filter. (New in Csound version 4.23f13 and 5.0)

## Performance

*ax, ay, az* -- the output x, y, and z coordinates of the planet

*kmass1* -- the mass of the first star

*kmass2* -- the mass of the second star

## Examples

Here is an example of the `planet` opcode. It uses the file `planet.csd` [examples/planet.csd].

### Example 633. Example of the planet opcode.

# platerev

platerev — Models the reverberation of a metal plate.

## Description

Models the reverberation of a rectangular metal plate with settable physical characteristics when excited by audio signal(s).

## Syntax

```
a1[, a2, ...] platerev itabexcite. itabouts, kbndry, iaspect, istiff, idecay, iloss, aexcite1[, aexcite2]
```

## Initialization

*itabexcite* -- number of a table that contains triplets for each excitation signal, (frequency, radius, initial phase in radians). The radius should be less than 1. These control where the excitation happens. The values in the table for frequency and radius may be changed in performance, with the proviso about clicking if the changes are too large.

*itabouts* -- number of a table that contains triplets for each output signal, (frequency, radius, initial phase in radians). See *itabexcite* description.

*kbndry* -- boundary condition of the plate; 0 = free, 1 = clamped, 2 = pivoting. Other values are undefined. Thus parameter may be changed at k-rate but that might give rise to clicks.

*iaspect* -- plate aspect ratio which should be less than or equal to 1.

*istiff* -- plate stiffness parameter (set around 1 or less for plate reverb).

*idecay* -- time taken for 30 dB decay

*iloss* -- loss parameter for high-frequency damping (value about 0.001 suggested).

## Performance

A metal plate is excited by a stereo signal and the resulting reverberation captured.

*aexcite1* -- excitation signal to be inserted into the plate.

## Examples

Here is an example of the *platerev* opcode. It uses the file *plate.csd* [examples/plate.csd].

### Example 634. Example of the *platerev* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# plltrack

`plltrack` — Tracks the pitch of a signal.

## Description

`plltrack`, a pitch tracker based on a phase-locked loop algorithm, described in Zolzer, U, Sankarababu, S.V. and Moller, S, "PLL-based Pitch Detection and Tracking for Audio Signals. Proc. of IIH-MSP 2012".

## Syntax

```
acps, alock plltrack asig, kd [, kloopf, kloopq, klf, khf, kthresh]
```

## Performance

`acps` -- estimated pitch in Hz.

`alock` -- phase lock indicator, a phase error indicating the quality of the tracking, with values between 0 and 1. Higher values indicate good tracking

`kd` -- PLL feedback gain, controls frequency range of PLL (between 0 and 1). Higher values increase the range of the tracking.

`kloopf` -- PLL LP filter cf, controls frequency range of PLL (opt, defaults to 20Hz).

`kloopq` -- PLL LP filter Q, controls rise time of FO step (opt, defaults to 1/3)

`klf` -- lowest tracking freq (opt, defaults to 20Hz)

`khf` -- highest tracking freq (opt, defaults to 1500Hz)

`kthresh` -- tracking signal level threshold (optional, defaults to 0.001, equiv to -60dBfs)

`plltrack` analyzes the input signal, `asig`, estimating the fundamental of a monophonic signal. Its output is updated every sample.

## Examples

Here is an example of the `plltrack` operator. It uses the file `plltrack.csd` [examples/plltrack.csd].

### Example 635. Example of the `plltrack` operator.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pluck

`pluck` — Produces a naturally decaying plucked string or drum sound.

## Description

Audio output is a naturally decaying plucked string or drum sound based on the Karplus-Strong algorithms.

## Syntax

```
ares pluck kamp, kcps, icps, ifn, imeth [, iparm1] [, iparm2]
```

## Initialization

*icps* -- intended pitch value in Hz, used to set up a buffer of 1 cycle of audio samples which will be smoothed over time by a chosen decay method. *icps* normally anticipates the value of *kcps*, but may be set artificially high or low to influence the size of the sample buffer.

*ifn* -- table number of a stored function used to initialize the cyclic decay buffer. If *ifn* = 0, a random sequence will be used instead.

*imeth* -- method of natural decay. There are six, some of which use parameters values that follow.

1. simple averaging. A simple smoothing process, uninfluenced by parameter values.
2. stretched averaging. As above, with smoothing time stretched by a factor of *iparm1* ( $\geq 1$ ).
3. simple drum. The range from pitch to noise is controlled by a 'roughness factor' in *iparm1* (0 to 1). Zero gives the plucked string effect, while 1 reverses the polarity of every sample (octave down, odd harmonics). The setting .5 gives an optimum snare drum.
4. stretched drum. Combines both roughness and stretch factors. *iparm1* is roughness (0 to 1), and *iparm2* the stretch factor ( $\geq 1$ ).
5. weighted averaging. As method 1, with *iparm1* weighting the current sample (the status quo) and *iparm2* weighting the previous adjacent one. *iparm1* + *iparm2* must be  $\leq 1$ .
6. 1st order recursive filter, with coeffs .5. Unaffected by parameter values.

*iparm1*, *iparm2* (optional) -- parameter values for use by the smoothing algorithms (above). The default values are both 0.

## Performance

*kamp* -- the output amplitude.

*kcps* -- the resampling frequency in cycles-per-second.

An internal audio buffer, filled at i-time according to *ifn*, is continually resampled with periodicity *kcps* and the resulting output is multiplied by *kamp*. Parallel with the sampling, the buffer is smoothed to sim-

ulate the effect of natural decay.

Plucked strings (1, 2, 5, 6) are best realized by starting with a random noise source, which is rich in initial harmonics. Drum sounds (methods 3, 4) work best with a flat source (wide pulse), which produces a deep noise attack and sharp decay.

The original Karplus-Strong algorithm used a fixed number of samples per cycle, which caused serious quantization of the pitches available and their intonation. This implementation resamples a buffer at the exact pitch given by *kcps*, which can be varied for vibrato and glissando effects. For low values of the orch sampling rate (e.g. *sr* = 10000), high frequencies will store only very few samples (*sr / icps*). Since this may cause noticeable noise in the resampling process, the internal buffer has a minimum size of 64 samples. This can be further enlarged by setting *icps* to some artificially lower pitch.

## Examples

Here is an example of the pluck opcode. It uses the file *pluck.csd* [examples/pluck.csd].

### Example 636. Example of the pluck opcode.

# poisson

`poisson` — Poisson distribution random number generator (positive values only).

## Description

Poisson distribution random number generator (positive values only). This is an x-class noise generator.

## Syntax

```
ares poisson klambda  
  
ires poisson klambda  
  
kres poisson klambda
```

## Performance

`ares`, `kres`, `ires` - number of events occurring (always an integer).

`klambda` - the expected number of occurrences that occur during the rate interval.

## Adapted from Wikipedia:

In probability theory and statistics, the Poisson distribution is a discrete probability distribution. It expresses the probability of a number of events occurring in a fixed period of time if these events occur with a known average rate, and are independent of the time since the last event.

The Poisson distribution describing the probability that there are exactly  $k$  occurrences ( $k$  being a non-negative integer,  $k = 0, 1, 2, \dots$ ) is:

$$f(k; \lambda) = \frac{e^{-\lambda} \lambda^k}{k!},$$

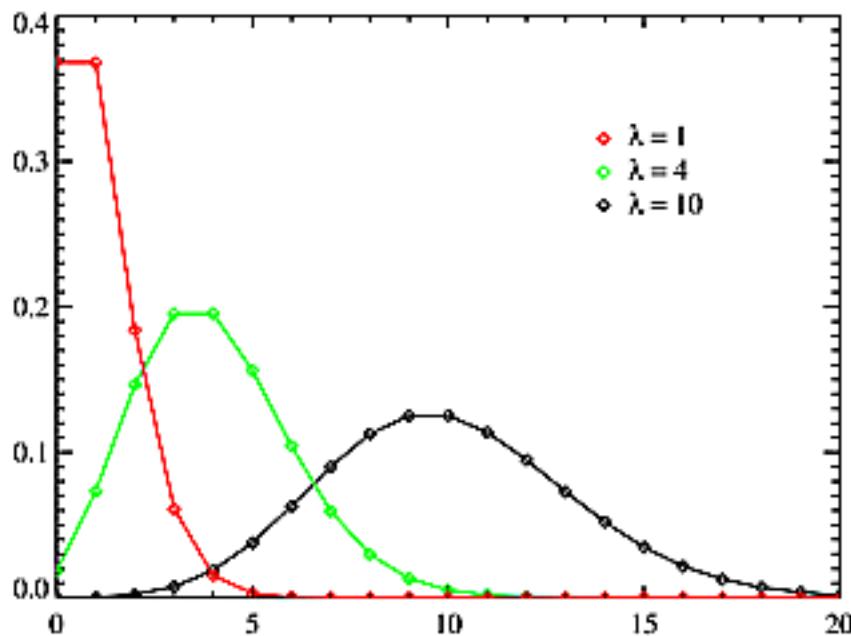

where:

- $\lambda$  is a positive real number, equal to the expected number of occurrences that occur during the given interval. For instance, if the events occur on average every 4 minutes, and you are interested in the number of events occurring in a 10 minute interval, you would use as model a Poisson distribution with  $\lambda = 10/4 = 2.5$ . This parameter is called *klambda* on the *poisson* opcodes.
- $k$  refers to the number of i-, k- or a- periods elapsed.

The Poisson distribution arises in connection with Poisson processes. It applies to various phenomena of discrete nature (that is, those that may happen 0, 1, 2, 3, ... times during a given period of time or in a given area) whenever the probability of the phenomenon happening is constant in time or space. Examples of events that can be modelled as Poisson distributions include:

- The number of cars that pass through a certain point on a road (sufficiently distant from traffic lights) during a given period of time.

- The number of spelling mistakes one makes while typing a single page.
- The number of phone calls at a call center per minute.
- The number of times a web server is accessed per minute.
- The number of roadkill (animals killed) found per unit length of road.
- The number of mutations in a given stretch of DNA after a certain amount of radiation.
- The number of unstable nuclei that decayed within a given period of time in a piece of radioactive substance. The radioactivity of the substance will weaken with time, so the total time interval used in the model should be significantly less than the mean lifetime of the substance.
- The number of pine trees per unit area of mixed forest.
- The number of stars in a given volume of space.
- The distribution of visual receptor cells in the retina of the human eye.
- The number of viruses that can infect a cell in cell culture.

A diagram showing the Poisson distribution.

For more detailed explanation of these distributions, see:

1. C. Dodge - T.A. Jerse 1985. Computer music. Schirmer books. pp.265 - 286
2. D. Lorrain. A panoply of stochastic cannons. In C. Roads, ed. 1989. Music machine . Cambridge, Massachusetts: MIT press, pp. 351 - 379.

## Examples

Here is an example of the poisson opcode. It uses the file *poisson.csd* [examples/poisson.csd]. It is written for \*NIX systems, and will generate errors on Windows.

# pol2rect

pol2rect — Polar to rectangular format conversion.

## Description

Converts an input array in magnitude-phase format to real-imaginary format.

## Syntax

```
kout[] pol2rect kin[]  
  
kout[] pol2rect kmags[], kphs[]
```

## Performance

*kout[]* -- output array containing the complex-valued real-imaginary output. It will be created if it does not exist.

*kin[]* -- input array containing the complex-valued magnitude-phase input.

*kmags[]* -- input array containing the real-valued magnitude input.

*kphs[]* -- input array containing the real-valued phase input.

## Examples

Here is an example of the pol2rect opcode. It uses the file *pol2rect.csd* [examples/pol2rect.csd].

# polyaft

`polyaft` — Returns the polyphonic after-touch pressure of the selected note number.

## Description

`polyaft` returns the polyphonic pressure of the selected note number, optionally mapped to an user-specified range.

## Syntax

```
ires polyaft inote [, ilow] [, ihigh]
```

```
kres polyaft inote [, ilow] [, ihigh]
```

## Initialization

*inote* -- note number. Normally set to the value returned by *notnum*

*ilow* (optional, default: 0) -- lowest output value

*ihigh* (optional, default: 127) -- highest output value

## Performance

*kres* -- polyphonic pressure (aftertouch).

## Examples

Here is an example of the `polyaft` opcode. It uses the file `polyaft.csd` [examples/polyaft.csd].

Don't forget that you must include the `-F` flag when using an external MIDI file like "polyaft.mid".

### Example 639. Example of the `polyaft` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# polynomial

`polynomial` — Efficiently evaluates a polynomial of arbitrary order.

## Description

The `polynomial` opcode calculates a polynomial with a single a-rate input variable. The polynomial is a sum of any number of terms in the form  $kn*x^n$  where  $kn$  is the nth coefficient of the expression. These coefficients are k-rate values.

## Syntax

```
aout polynomial ain, k0 [, k1 [, k2 [...]]]
```

## Performance

*ain* -- the input signal used as the independent variable of the polynomial ("x").

*aout* -- the output signal ("y").

*k0, k1, k2, ...* -- the coefficients for each term of the polynomial.

If we consider the input parameter *ain* to be "x" and the output *aout* to be "y", then the `polynomial` opcode calculates the following equation:

$$y = k0 + k1*x + k2*x^2 + k3*x^3 + \dots$$

## Examples

Here is an example of the polynomial opcode. It uses the file `polynomial.csd` [examples/polynomial.csd].

### Example 640. Example of the polynomial opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# port

`port` — Applies portamento to a step-valued control signal.

## Description

Applies portamento to a step-valued control signal.

## Syntax

```
kres port ksig, ihtim [, isig]
```

## Initialization

*ihtim* -- half-time of the function, in seconds.

*isig* (optional, default=0) -- initial (i.e. previous) value for internal feedback. The default value is 0. Negative value will cause initialization to be skipped and last value from previous instance to be used as initial value for note.

## Performance

*kres* -- the output signal at control-rate.

*ksig* -- the input signal at control-rate.

*port* applies portamento to a step-valued control signal. At each new step value, *ksig* is low-pass filtered to move towards that value at a rate determined by *ihtim*. *ihtim* is the “half-time” of the function (in seconds), during which the curve will traverse half the distance towards the new value, then half as much again, etc., theoretically never reaching its asymptote. With *portk*, the half-time can be varied at the control rate.

## Examples

Here is an example of the *port* opcode. It uses the file *port.csd* [examples/port.csd].

### Example 641. Example of the port opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# portk

portk — Applies portamento to a step-valued control signal.

## Description

Applies portamento to a step-valued control signal.

## Syntax

```
kres portk ksig, khtim [, isig]
```

## Initialization

*isig* (optional, default=0) -- initial (i.e. previous) value for internal feedback. The default value is 0.

## Performance

*kres* -- the output signal at control-rate.

*ksig* -- the input signal at control-rate.

*khtim* -- half-time of the function in seconds.

*portk* is like *port* except the half-time can be varied at the control rate.

## Examples

Here is an example of the portk opcode. It uses the file *portk.csd* [examples/portk.csd].

### Example 642. Example of the portk opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# poscil3

poscil3 — High precision oscillator with cubic interpolation.

## Description

High precision oscillator with cubic interpolation.

## Syntax

```
ares poscil3 aamp, acps [, ifn, iphs]  
  
ares poscil3 aamp, kcps [, ifn, iphs]  
  
ares poscil3 kamp, acps [, ifn, iphs]  
  
ares poscil3 kamp, kcps [, ifn, iphs]  
  
ires poscil3 kamp, kcps [, ifn, iphs]  
  
kres poscil3 kamp, kcps [, ifn, iphs]
```

## Initialization

*ifn* -- (optional) function table number. This defaults to -1 which indicates a sinewave.

*iphs* (optional, default=0) -- initial phase (normalized table index 0-1). If a negative value is given initialisation of the phase is skipped.

## Performance

*ares* -- output signal

*kamp, aamp* -- the amplitude of the output signal.

*kcps, acps* -- the frequency of the output signal in cycles per second.

*poscil3* works like *poscil*, but uses cubic interpolation.

Note that *poscil3* can use defered (non-power of two) length tables.

## Examples

Here is an example of the poscil3 opcode. It uses the file *poscil3.csd* [examples/poscil3.csd].

### Example 643. Example of the poscil3 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# poscil

*poscil* — High precision oscillator.

## Description

High precision oscillator.

## Syntax

```
ares poscil aamp, acps [, ifn, iphs]  
  
ares poscil aamp, kcps [, ifn, iphs]  
  
ares poscil kamp, acps [, ifn, iphs]  
  
ares poscil kamp, kcps [, ifn, iphs]  
  
ires poscil kamp, kcps [, ifn, iphs]  
  
kres poscil kamp, kcps [, ifn, iphs]
```

## Initialization

*ifn* -- (optional) function table number. This defaults to -1 which indicates a sinewave.

*iphs* (optional, default=0) -- initial phase (normalized table index 0-1). If a negative value is given initialisation of the phase is skipped.

## Performance

*ares* -- output signal

*kamp, aamp* -- the amplitude of the output signal.

*kcps, acps* -- the frequency of the output signal in cycles per second.

*poscil* (precise oscillator) is the same as *oscili*, but allows much more precise frequency control, especially when using long tables and low frequency values. It uses floating-point table indexing, instead of integer math, like *oscil* and *oscili*. It is only a bit slower than *oscili*.

Since Csound 4.22, *poscil* can accept also negative frequency values and use a-rate values both for amplitude and frequency. So both AM and FM are allowed using this opcode.

The opcode *poscil3* is the same as *poscil*, but uses cubic interpolation.

Note that *poscil* can use deffered (non-power of two) length tables.

## Examples

Here is an example of the *poscil* opcode. It uses the file *poscil.csd* [examples/poscil.csd].

### Example 645. Example of the poscil opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pow

`pow` — Computes one argument to the power of another argument.

## Description

Computes *xarg* to the power of *kpow* (or *ipow*) and scales the result by *inorm*.

## Syntax

```
ares pow aarg, kpow [, inorm]  
  
ires pow iarg, ipow [, inorm]  
  
kres pow karg, kpow [, inorm]
```

## Initialization

*inorm* (optional, default=1) -- The number to divide the result (default to 1). This is especially useful if you are doing powers of a- or k- signals where samples out of range are extremely common!

## Performance

*aarg*, *iarg*, *karg* -- the base.

*ipow*, *kpow* -- the exponent.

### Note

Use ^ with caution in arithmetical statements, as the precedence may not be correct. New in Csound version 3.493.

## Examples

Here is an example of the `pow` opcode. It uses the file `pow.csd` [examples/pow.csd].

# powershape

`powershape` — Waveshapes a signal by raising it to a variable exponent.

## Description

The `powershape` opcode raises an input signal to a power with pre- and post-scaling of the signal so that the output will be in a predictable range. It also processes negative inputs in a symmetrical way to positive inputs, calculating a dynamic transfer function that is useful for waveshaping.

## Syntax

```
aout powershape ain, kShapeAmount [, ifullscale]
```

## Initialization

*ifullscale* -- optional parameter specifying the range of input values from *-ifullscale* to *ifullscale*. Defaults to 1.0 -- you should set this parameter to the maximum expected input value.

## Performance

*ain* -- the input signal to be shaped.

*aout* -- the output signal.

*kShapeAmount* -- the amount of the shaping effect applied to the input; equal to the power that the input signal is raised.

The `powershape` opcode is very similar to the `pow` unit generators for calculating the mathematical "power of" operation. However, it introduces a couple of twists that can make it much more useful for waveshaping audio-rate signals. The *kShapeAmount* parameter is the exponent to which the input signal is raised.

To avoid discontinuities, the `powershape` opcode treats all input values as positive (by taking their absolute value) but preserves their original sign in the output signal. This allows for smooth shaping of any input signal while varying the exponent over any range. (`powershape` also (hopefully) deals intelligently with discontinuities that could arise when the exponent and input are both zero. Note though that negative exponents will usually cause the signal to exceed the maximum amplitude specified by the *ifullscale* parameter and should normally be avoided).

The other adaptation involves the *ifullscale* parameter. The input signal is divided by *ifullscale* before being raised to *kShapeAmount* and then multiplied by *ifullscale* before being output. This normalizes the input signal to the interval [-1,1], guaranteeing that the output (before final scaling) will also be within this range for positive shaping amounts and providing a smoothly evolving transfer function while varying the amount of shaping. Values of *kShapeAmount* between (0,1) will make the signal more "convex" while values greater than 1 will make it more "concave". A value of exactly 1.0 will produce no change in the input signal.

# powoftwo

powoftwo — Performs a power-of-two calculation.

## Description

Performs a power-of-two calculation.

## Syntax

```
powoftwo(x)  (init-rate or control-rate args only)
```

## Performance

*powoftwo()* function returns  $2^x$  and allows positive and negative numbers as argument. The range of values admitted in *powoftwo()* is -5 to +5 allowing a precision more fine than one cent in a range of ten octaves. If a greater range of values is required, use the slower opcode *pow*.

These functions are fast, because they read values stored in tables. Also they are very useful when working with tuning ratios. They work at i- and k-rate.

## Examples

Here is an example of the powoftwo opcode. It uses the file *powoftwo.csd* [examples/powoftwo.csd].

### Example 648. Example of the powoftwo opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# prealloc

prealloc — Creates space for instruments but does not run them.

## Description

Creates space for instruments but does not run them.

## Syntax

```
prealloc insnum, ictcount  
prealloc "insname", ictcount
```

## Initialization

*insnum* -- instrument number

*ictcount* -- number of instrument allocations

“*insname*” -- A string (in double-quotes) representing a named instrument.

## Performance

All instances of *prealloc* must be defined in the header section, not in the instrument body.

## Examples

Here is an example of the prealloc opcode. It uses the file *prealloc.csd* [examples/prealloc.csd].

### Example 649. Example of the prealloc opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# prepiano

prepiano — Creates a tone similar to a piano string prepared in a Cageian fashion.

## Description

Audio output is a tone similar to a piano string, prepared with a number of rubbers and rattles. The method uses a physical model developed from solving the partial differential equation.

## Syntax

```
ares prepiano ifreq, iNS, iD, iK, \
      iT30,ib, kbcl, kbcr, imass, ihvfreq, iinit, ipos, ivel, isfreq, \
      isspread[, irattles, irubbers]

al,ar prepiano ifreq, iNS, iD, iK, \
      iT30,ib, kbcl, kbcr, imass, ihvfreq, iinit, ipos, ivel, isfreq, \
      isspread[, irattles, irubbers]
```

## Initialization

*ifreq* -- The base frequency of the string.

*iNS* -- the number of strings involved. In a real piano 1, 2 or 3 strings are found in different frequency regions.

*iD* -- the amount each string other than the first is detuned from the main frequency, measured in cents.

*iK* -- dimensionless stiffness parameter.

*iT30* -- 30 db decay time in seconds.

*ib* -- high-frequency loss parameter (keep this small).

*imass* -- the mass of the piano hammer.

*ihvfreq* -- the frequency of the natural vibrations of the hammer.

*iinit* -- the initial position of the hammer.

*ipos* -- position along the string that the strike occurs.

*ivel* -- normalized strike velocity.

*isfreq* -- scanning frequency of the reading place.

*isspread* -- scanning frequency spread.

*irattles* -- table number giving locations of any rattle(s).

*irubbers* -- table number giving locations of any rubbers(s).

The rattles and rubbers tables are collections of four values, preceded by a count. In the case of a rattle the four are position, mass density ratio of rattle/string, frequency of rattle and vertical length of the rattle. For the rubber the fours are position, mass density ratio of rubber/string, frequency of rubber and

the loss parameter.

## Performance

A note is played on a piano string, with the arguments as below.

*kbcL* -- Boundary condition at left end of string (1 is clamped, 2 pivoting and 3 free).

*kbcR* -- Boundary condition at right end of string (1 is clamped, 2 pivoting and 3 free).

Note that changing the boundary conditions during playing may lead to glitches and is made available as an experiment.

## Examples

Here is an example of the prepiano opcode. It uses the file *prepiano.csd* [examples/prepiano.csd].

### Example 650. Example of the prepiano opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# print

print — Displays the values init (i-rate) variables.

## Description

These units will print orchestra init-values.

## Syntax

```
print iarg [, iarg1] [, iarg2] [...]
```

## Initialization

*iarg, iarg2, ...* -- i-rate arguments.

## Performance

*print* -- print the current value of the i-time arguments (or expressions) *iarg* at every i-pass through the instrument.

### Note

The *print* opcode will truncate decimal places and may not show the complete value. Csound's precision depends on whether it is the floats (32-bit) or double (64-bit) *version*, since most internal calculations use one of these formats. If you need more resolution in the console output, you can try *printf*.

## Examples

Here is an example of the print opcode. It uses the file *print.csd* [examples/print.csd].

### Example 651. Example of the print opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# printf

printf — printf-style formatted output

## Description

**printf** and **printf\_i** write formatted output, similarly to the C function printf(). **printf\_i** runs at i-time only, while **printf** runs both at initialization and performance time.

## Syntax

```
printf_i Sfmt, itrig, [iarg1[, iarg2[, ... ]]]
```

```
printf Sfmt, ktrig, [xarg1[, xarg2[, ... ]]]
```

## Initialization

*Sfmt* -- format string, has the same format as in printf() and other similar C functions, except length modifiers (l, ll, h, etc.) are not supported. The following conversion specifiers are allowed:

- d, i, o, u, x, X, e, E, f, F, g, G, c, s

*iarg1*, *iarg2*, ... -- input arguments (max. 30) for format. Integer formats like %d round the input values to the nearest integer.

*itrig* -- if greater than zero the opcode performs the printing; otherwise it is an null operation.

## Performance

*ktrig* -- if greater than zero and different from the value on the previous control cycle the opcode performs the requested printing. Initially this previous value is taken as zero.

*xarg1*, *xarg2*, ... -- input arguments (max. 30) for format. Integer formats like %d round the input values to the nearest integer. Note that only k-rate and i-rate arguments are valid (no a-rate printing)

## Examples

Here is an example of the printf opcode. It uses the file *printf.csd* [examples/printf.csd].

### Example 652. Example of the printf opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>

# printf2

printf2 — Prints a new value every time a control variable changes.

## Description

Prints a new value every time a control variable changes.

## Syntax

```
printf2 kvar [, inumspaces]
```

## Initialization

*inumspaces* (optional, default=0) -- number of space characters printed before the value of *kvar*

## Performance

*kvar* -- signal to be printed

Derived from Robin Whittle's *printf*, prints a new value of *kvar* each time *kvar* changes. Useful for monitoring MIDI control changes when using sliders.

### Warning

*WARNING!* Don't use this opcode with normal, continuously variant k-signals, because it can hang the computer, as the rate of printing is too fast.

## Examples

Here is an example of the printf2 opcode. It uses the file *printf2.csd* [examples/printf2.csd].

### Example 653. Example of the printf2 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# printk

printk — Prints one k-rate value at specified intervals.

## Description

Prints one k-rate value at specified intervals.

## Syntax

```
printk itime, kval [, ispace]
```

## Initialization

*itime* -- time in seconds between printings.

*ispace* (optional, default=0) -- number of spaces to insert before printing. (default: 0, max: 130)

## Performance

*kval* -- The k-rate values to be printed.

*printk* prints one k-rate value on every k-cycle, every second or at intervals specified. First the instrument number is printed, then the absolute time in seconds, then a specified number of spaces, then the *kval* value. The variable number of spaces enables different values to be spaced out across the screen - so they are easier to view.

This opcode can be run on every k-cycle it is run in the instrument. To every accomplish this, set *itime* to 0.

When *itime* is not 0, the opcode print on the first k-cycle it is called, and subsequently when every *itime* period has elapsed. The time cycles start from the time the opcode is initialized - typically the initialization of the instrument.

## Examples

Here is an example of the *printk* opcode. It uses the file *printk.csd* [examples/printk.csd].

### Example 654. Example of the *printk* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# printks

printks — Prints at k-rate using a printf() style syntax.

## Description

Prints at k-rate using a printf() style syntax.

## Syntax

```
printks "string", itime [, kval1] [, kval2] [...]
```

## Initialization

"*string*" -- the text string to be printed. Can be up to 8192 characters and must be in double quotes.

*itime* -- time in seconds between printings.

## Performance

*kval1*, *kval2*, ... (optional) -- The k-rate values to be printed. These are specified in "*string*" with the standard C value specifier (%f, %d, etc.) in the order given.

In Csound version 4.23, you can use as many *kval* variables as you like. In versions prior to 4.23, you must specify 4 and only 4 kvals (using 0 for unused kvals).

*printks* prints numbers and text which can be i-time or k-rate values. *printks* is highly flexible, and if used together with cursor positioning codes, could be used to write specific values to locations in the screen as the Csound processing proceeds.

A special mode of operation allows this *printks* to convert *kval1* input parameter into a 0 to 255 value and to use it as the first character to be printed. This enables a Csound program to send arbitrary characters to the console. To achieve this, make the first character of the string a # and then, if desired continue with normal text and format specifiers.

This opcode can be run on every k-cycle it is run in the instrument. To every accomplish this, set *itime* to 0.

When *itime* is not 0, the opcode print on the first k-cycle it is called, and subsequently when every *itime* period has elapsed. The time cycles start from the time the opcode is initialized - typically the initialization of the instrument.

## Print Output Formatting

All standard C language printf() control characters may be used. For example, if *kval1* = 153.26789 then some common formatting options are:

1. %f prints with full precision: 153.26789
2. %5.2f prints: 153.26
3. %d prints integers-only: 153

4. %c treats *kval1* as an ascii character code.

In addition to all the printf() codes, printk supports these useful character codes:

| printks Code      | Character Code  |
|-------------------|---|
| \r, \R, %r, or %R | return character (\r)   |
| \n, \N, %n, %N    | newline character (\n)  |
| \t, \T, %t, or %T | tab character (\t)  |
| %!                | semicolon character (;) This was needed because a “;” is interpreted as an comment. |
| ^                 | escape character (0x1B)   |
| ^ ^               | caret character (^)   |
| ~                 | ESC[ (escape+[ is the escape sequence for ANSI consoles)                            |
| ~                 | tilde (~)   |

For more information about printf() formatting, consult any C language documentation.

## Note

Prior to version 4.23, only the %f format code was supported.

# Examples

Here is an example of the printk opcode. It uses the file *printks.csd* [examples/printks.csd].

Thanks goes to Luis Jure for pointing out a mistake with the *itime* parameter.

Thanks to Matt Ingalls, updated the documentation for version 4.23.

# printks2

printks2 — Prints a new value every time a control variable changes using a printf() style syntax.

## Description

Prints a new value every time a control variable changes using a printf() style syntax.

## Syntax

```
printks2 "string", kval
```

## Initialization

"*string*" -- the text string to be used as a format.

## Performance

*kval* -- signal to be printed. The style of printing is specified in "*string*" with the standard C value specifier (%f, %d, etc.).

## Print Output Formatting

All standard C language printf() control characters may be used. For example, if *kval1* = 153.26789 then some common formatting options are:

1. %f prints with full precision: 153.26789
2. %5.2f prints: 153.26
3. %d prints integers-only: 153
4. %c treats *kval1* as an ascii character code.

In addition to all the printf() codes, printks2 supports these useful character codes:

| printks2 Code      | Character Code  |
|--------------------|---|
| \\r, \R, %r, or %R | return character (\r)   |
| \\n, \N, %n, %N    | newline character (\n)  |
| \\t, \T, %t, or %T | tab character (\t)  |
| %!                 | semicolon character (;) This was needed because a ";" is interpreted as an comment. |
| ^                  | escape character (0x1B)   |
| ^ ^                | caret character (^)   |
| ~                  | ESC[ (escape+[ is the escape sequence for ANSI consoles)                            |
| ~~                 | tilde (~)   |

For more information about printf() formatting, consult any C language documentation.

## Examples

Here is an example of the printks2 opcode. It uses the file *printks2.csd* [examples/printks2.csd].

### Example 656. Example of the printks2 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# prints

`prints` — Prints at init-time using a printf() style syntax.

## Description

Prints at init-time using a printf() style syntax.

## Syntax

```
prints "string" [, kval1] [, kval2] [...]
```

## Initialization

`"string"` -- the text string to be printed. Can be up to 8192 characters and must be in double quotes.

## Performance

`kval1, kval2, ...` (optional) -- The k-rate values to be printed. These are specified in `"string"` with the standard C value specifier (%f, %d, etc.) in the order given. Use 0 for those which are not used.

`prints` is similar to the `printks` opcode except it operates at init-time instead of k-rate. For more information about output formatting, please look at `printks`'s documentation.

## Examples

Here is an example of the `prints` opcode. It uses the file `prints.csd` [examples/prints.csd].

### Example 657. Example of the prints opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>

# pset

pset — Defines and initializes numeric arrays at orchestra load time.

## Description

Defines and initializes numeric arrays at orchestra load time.

## Syntax

```
pset icon1 [, icon2] [...]
```

## Initialization

*icon1, icon2, ...* -- preset values for a MIDI instrument

*pset* (optional) defines and initializes numeric arrays at orchestra load time. It may be used as an orchestra header statement (i.e. instrument 0) or within an instrument. When defined within an instrument, it is not part of its i-time or performance operation, and only one statement is allowed per instrument. These values are available as i-time defaults. When an instrument is triggered from MIDI it only gets p1 and p2 from the event, and p3, p4, etc. will receive the actual preset values.

## Examples

Here is an example of the pset opcode. It uses the file *pset.csd* [examples/pset.csd]

### Example 659. Example of the pset opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# ptable

ptable — Accesses table values by direct indexing.

## Description

Accesses table values by direct indexing.

## Syntax

```
ares ptable andx, ifn [, ixmode] [, ixoff] [, iwrap]  
  
ires ptable indx, ifn [, ixmode] [, ixoff] [, iwrap]  
  
kres ptable kndx, ifn [, ixmode] [, ixoff] [, iwrap]
```

## Initialization

*ifn* -- function table number.

*ixmode* (optional) -- index data mode. The default value is 0.

- 0 = raw index
- 1 = normalized (0 to 1)

*ixoff* (optional) -- amount by which index is to be offset. For a table with origin at center, use tablesiz/2 (raw) or .5 (normalized). The default value is 0.

*iwrap* (optional) -- wraparound index flag. The default value is 0.

- 0 = nowrap (index < 0 treated as index=0; index > tablesiz sticks at index=siz)
- 1 = wraparound.

## Performance

*ptable* invokes table lookup on behalf of init, control or audio indices. These indices can be raw entry numbers (0, 1, 2,... size - 1) or scaled values (0 to 1). Indices are first modified by the offset value then checked for range before table lookup (see *iwrap*). If index is likely to be full scale, or if interpolation is being used, the table should have an extended guard point. *table* indexed by a periodic phasor ( see *phasor*) will simulate an oscillator.

## Examples

Here is an example of the ptable opcode. It uses the file *ptable.csd* [examples/ptable.csd].

### Example 661. Example of the ptable opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# ptablei

*ptablei* — Accesses table values by direct indexing with linear interpolation.

## Description

Accesses table values by direct indexing with linear interpolation.

## Syntax

```
ares ptablei andx, ifn [, ixmode] [, ixoff] [, iwrap]  
  
ires ptablei indx, ifn [, ixmode] [, ixoff] [, iwrap]  
  
kres ptablei kndx, ifn [, ixmode] [, ixoff] [, iwrap]
```

## Initialization

*ifn* -- function table number. The table need not be a power of 2 long.

*ixmode* (optional) -- index data mode. The default value is 0.

- 0 = raw index
- 1 = normalized (0 to 1)

*ixoff* (optional) -- amount by which index is to be offset. For a table with origin at center, use tablesiz/2 (raw) or .5 (normalized). The default value is 0.

*iwrap* (optional) -- wraparound index flag. The default value is 0.

- 0 = nowrap (index < 0 treated as index=0; index > tablesiz sticks at index=siz)
- 1 = wraparound.

## Performance

*ptablei* is a interpolating unit in which the fractional part of index is used to interpolate between adjacent table entries. The smoothness gained by interpolation is at some small cost in execution time (see also *oscili*, etc.), but the interpolating and non-interpolating units are otherwise interchangeable.

## Examples

Here is an example of the *ptablei* opcode. It uses the file *ptablei.csd* [examples/ptablei.csd].

### Example 662. Example of the *ptablei* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# ptable3

`ptable3` — Accesses table values by direct indexing with cubic interpolation.

## Description

Accesses table values by direct indexing with cubic interpolation.

## Syntax

```
ares ptable3 andx, ifn [, ixmode] [, ixoff] [, iwrap]  
  
ires ptable3 indx, ifn [, ixmode] [, ixoff] [, iwrap]  
  
kres ptable3 kndx, ifn [, ixmode] [, ixoff] [, iwrap]
```

## Initialization

*ifn* -- function table number.

*ixmode* (optional) -- index data mode. The default value is 0.

- 0 = raw index
- 1 = normalized (0 to 1)

*ixoff* (optional) -- amount by which index is to be offset. For a table with origin at center, use `tablesize/2` (raw) or `.5` (normalized). The default value is 0.

*iwrap* (optional) -- wraparound index flag. The default value is 0.

- 0 = nowrap (index < 0 treated as index=0; index > `tablesize` sticks at index=`size`)
- 1 = wraparound.

## Performance

`ptable3` is identical to `table3`, except that it uses does not require the table to have a power of two size.

# ptablew

**ptablew** — Change the contents of existing function tables of any length.

## Description

This opcode operates on existing function tables, changing their contents. *ptablew* is for writing at k- or at a-rates, with the table number being specified at init time. Using *ptablew* with i-rate signal and index values is allowed, but the specified data will always be written to the function table at k-rate, not during the initialization pass. The valid combinations of variable types are shown by the first letter of the variable names.

## Syntax

```
ptablew asig, andx, ifn [, ixmode] [, ixoff] [, iwgmode]  
  
ptablew isig, indx, ifn [, ixmode] [, ixoff] [, iwgmode]  
  
ptablew ksig, kndx, ifn [, ixmode] [, ixoff] [, iwgmode]
```

## Initialization

*asig, isig, ksig* -- The value to be written into the table.

*andx, indx, kndx* -- Index into table, either a positive number range matching the table length (*ixmode* = 0) or a 0 to 1 range (*ixmode* != 0)

*ifn* -- Table number. Must be  $\geq 1$ . Floats are rounded down to an integer. If a table number does not point to a valid table, or the table has not yet been loaded (*GEN01*) then an error will result and the instrument will be de-activated.

*ixmode* (optional, default=0) -- index mode.

- 0 = *xndx* and *ixoff* ranges match the length of the table.
- !=0 = *xndx* and *ixoff* have a 0 to 1 range.

*ixoff* (optional, default=0) -- index offset.

- 0 = Total index is controlled directly by *xndx*, i.e. the indexing starts from the start of the table.
- !=0 = Start indexing from somewhere else in the table. Value must be positive and less than the table length (*ixmode* = 0) or less than 1 (*ixmode* != 0).

*iwgmode* (optional, default=0) -- Wrap and guardpoint mode.

- 0 = Limit mode.
- 1 = Wrap mode.

- 2 = Guardpoint mode.

## Performance

### Limit mode (0)

Limit the total index ( $ndx + ixoff$ ) to between 0 and the guard point. For a table of length 5, this means that locations 0 to 3 and location 4 (the guard point) can be written. A negative total index writes to location 0.

### Wrap mode (1)

Wrap total index value into locations 0 to E, where E is one less than the table length. For example, wrap into a 0 to 3 range - so that total index 6 writes to location 2.

### Guardpoint mode (2)

The guardpoint is written at the same time as location 0 is written - with the same value.

This facilitates writing to tables which are intended to be read with interpolation for producing smooth cyclic waveforms. In addition, before it is used, the total index is incremented by half the range between one location and the next, before being rounded down to the integer address of a table location.

Normally ( $igemode = 0$  or  $1$ ) for a table of length 5 - which has locations 0 to 3 as the main table and location 4 as the guard point, a total index in the range of 0 to 0.999 will write to location 0. ("0.999" means just less than 1.0.) 1.0 to 1.999 will write to location 1 etc. A similar pattern holds for all total indexes 0 to 4.999 ( $igemode = 0$ ) or to 3.999 ( $igemode = 1$ ).  $igemode = 0$  enables locations 0 to 4 to be written - with the guardpoint (4) being written with a potentially different value from location 0.

With a table of length 5 and the  $iwemode = 2$ , then when the total index is in the range 0 to 0.499, it will write to locations 0 and 4. Range 0.5 to 1.499 will write to location 1 etc. 3.5 to 4.0 will also write to locations 0 and 4.

This way, the writing operation most closely approximates the results of interpolated reading. Guard point mode should only be used with tables that have a guardpoint.

Guardpoint mode is accomplished by adding 0.5 to the total index, rounding to the next lowest integer, wrapping it modulo the factor of two which is one less than the table length, writing the table (locations 0 to 3 in our example) and then writing to the guard point if index = 0.

*ptablew* has no output value. The last three parameters are optional and have default values of 0.

## Caution with k-rate table numbers

At k-rate or a-rate, if a table number of < 1 is given, or the table number points to a non-existent table, or to one which has a length of 0 (it is to be loaded from a file later) then an error will result and the instrument will be deactivated. *kfn* and *afn* must be initialized at the appropriate rate using *init*. Attempting to load an i-rate value into *kfn* or *afn* will result in an error.

### Warning

 Note that *ptablew* is always a k-rate opcode. This means that even its i-rate version runs at k-rate and will write the value of the i-rate variable. For this reason, the following code will not work as expected:

```
<CsoundSynthesizer>
<CsOptions>
</CsOptions>
<CsInstruments>
giFt ftgen 1, 0, 8, 2, 0
instr 1
indx = 0
    ptablew 10, indx, giFt
ival tab_i indx, giFt
    print ival
endin
</CsInstruments>
<CsScore>
i 1 0 1
</CsScore>
</CsoundSynthesizer>
```

Although it may seem this program should print a 10 to the console. It will print 0, because *tab\_i* will read the value at the initialization of the note, before the first performance pass, when *ptablew* writes its value.

# ptrack

ptrack — Tracks the pitch of a signal.

## Description

*ptrack* takes an input signal, splits it into *ihopsize* blocks and using a STFT method, extracts an estimated pitch for its fundamental frequency as well as estimating the total amplitude of the signal in dB, relative to full-scale (0dB). The method implies an analysis window size of  $2 * \text{ihopsize}$  samples (overlapping by 1/2 window), which has to be a power-of-two, between 128 and 8192 (hopsizes between 64 and 4096). Smaller windows will give better time precision, but worse frequency accuracy (esp. in low fundamentals). This opcode is based on an original algorithm by M. Puckette.

## Syntax

```
kcps, kamp ptrack asig, ihopsize[,ipeaks]
```

## Initialization

*ihopsize* -- size of the analysis 'hop', in samples, required to be power-of-two (min 64, max 4096). This is the period between measurements.

*ipeaks*, *ihi* -- number of spectral peaks to use in the analysis, defaults to 20 (optional)

## Performance

*kcps* -- estimated pitch in Hz.

*kamp* -- estimated amplitude in dB relative to full-scale (0dB) (ie. always  $\leq 0$ ).

*ptrack* analyzes the input signal, *asig*, to give a pitch/amplitude pair of outputs, for the fundamental of a monophonic signal. The output is updated every  $sr/ihopsize$  seconds.

## Examples

Here is an example of the *ptrack* opcode. This example uses the files *ptrack.csd* [examples/ptrack.csd].

### Example 663. Example of the ptrack opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# puts

puts — Print a string constant or variable

## Description

puts prints a string with an optional newline at the end whenever the trigger signal is positive and changes.

## Syntax

```
puts Sstr, ktrig[, inonl]
```

## Initialization

*Sstr* -- string to be printed

*inonl* (optional, defaults to 0) -- if non-zero, disables the default printing of a newline character at the end of the string

## Performance

*ktrig* -- trigger signal, should be valid at i-time. The string is printed at initialization time if *ktrig* is positive, and at performance time whenever *ktrig* is both positive and different from the previous value. Use a constant value of 1 to print once at note initialization.

## Examples

Here is an example of the puts opcode. It uses the file *puts.csd* [examples/puts.csd].

### Example 664. Example of the puts opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac    ;;;realtime audio out

# pvadd

`pvadd` — Reads from a *pvoc* file and uses the data to perform additive synthesis.

## Description

*pvadd* reads from a *pvoc* file and uses the data to perform additive synthesis using an internal array of interpolating oscillators. The user supplies the wave table (usually one period of a sine wave), and can choose which analysis bins will be used in the re-synthesis.

## Syntax

```
ares pvadd ktmpnt, kfmod, ifilcod, ifn, ibins [, ibinoffset] \
[, ibinincr] [, iextractmode] [, ifreqlim] [, igatefn]
```

## Initialization

*ofilcod* -- integer or character-string denoting a control-file derived from *pvanal* analysis of an audio signal. An integer denotes the suffix of a file *pvoc.m*; a character-string (in double quotes) gives a filename, optionally a full pathname. If not fullpath, the file is sought first in the current directory, then in the one given by the environment variable *SADIR* (if defined). *pvoc* control files contain data organized for fft resynthesis. Memory usage depends on the size of the files involved, which are read and held entirely in memory during computation but are shared by multiple calls (see also *lspread*).

*ifn* -- table number of a stored function containing a sine wave.

*ibins* -- number of bins that will be used in the resynthesis (each bin counts as one oscillator in the re-synthesis)

*ibinoffset* (optional) -- is the first bin used (it is optional and defaults to 0).

*ibinincr* (optional) -- sets an increment by which *pvadd* counts up from *ibinoffset* for *ibins* components in the re-synthesis (see below for a further explanation).

*iextractmode* (optional) -- determines if spectral extraction will be carried out and if so whether components that have changes in frequency below *ifreqlim* or above *ifreqlim* will be discarded. A value for *iextractmode* of 1 will cause *pvadd* to synthesize only those components where the frequency difference between analysis frames is greater than *ifreqlim*. A value of 2 for *iextractmode* will cause *pvadd* to synthesize only those components where the frequency difference between frames is less than *ifreqlim*. The default values for *iextractmode* and *ifreqlim* are 0, in which case a simple resynthesis will be done. See examples below.

*igatefn* (optional) -- is the number of a stored function which will be applied to the amplitudes of the analysis bins before resynthesis takes place. If *igatefn* is greater than 0 the amplitudes of each bin will be scaled by *igatefn* through a simple mapping process. First, the amplitudes of all of the bins in all of the frames in the entire analysis file are compared to determine the maximum amplitude value. This value is then used to create normalized amplitudes as indices into the stored function *igatefn*. The maximum amplitude will map to the last point in the function. An amplitude of 0 will map to the first point in the function. Values between 0 and 1 will map accordingly to points along the function table. This will be made clearer in the examples below.

## Performance

*ktmpnt* and *kfmod* are used in the same way as in *pvoc*.

## Examples

```
ktyme line 0, p3, p3  
asig pvadd ktime, 1, "oboe.pvoc", 1, 100, 2
```

In the above, *ibins* is 100 and *ibinoffset* is 2. Using these settings the resynthesis will contain 100 components beginning with bin #2 (bins are counted starting with 0). That is, resynthesis will be done using bins 2-101 inclusive. It is usually a good idea to begin with bin 1 or 2 since the 0th and often 1st bin have data that is neither necessary nor even helpful for creating good clean resynthesis.

```
ktyme line 0, p3, p3  
asig pvadd ktime, 1, "oboe.pvoc", 1, 100, 2, 2
```

The above is the same as the previous example with the addition of the value 2 used for the optional *ibinincr* argument. This result will still result in 100 components in the resynthesis, but *pvadd* will count through the bins by 2 instead of by 1. It will use bins 2, 4, 6, 8, 10, and so on. For *ibins*=10, *ibinoffset*=10, and *ibinincr*=10, *pvadd* would use bins 10, 20, 30, 40, up to and including 100.

Below is an example using spectral extraction. In this example *iextractmode* is 1 and *ifreqlim* is 9. This will cause *pvadd* to synthesize only those bins where the frequency deviation, averaged over 6 frames, is greater than 9.

```
ktyme line 0, p3, p3  
asig pvadd ktime, 1, "oboe.pvoc", 1, 100, 2, 2, 1, 9
```

If *iextractmode* were 2 in the above, then only those bins with an average frequency deviation of less than 9 would be synthesized. If tuned correctly, this technique can be used to separate the pitched parts of the spectrum from the noisy parts. In practice this depends greatly on the type of sound, the quality of the recording and digitization, and also on the analysis window size and frame increment.

Next is an example using amplitude gating. The last 2 in the argument list stands for f2 in the score.

```
asig pvadd ktime, 1, "oboe.pvoc", 1, 100, 2, 2, 0, 0, 2
```

Suppose the score for the above were to contain:

```
f2 0 512 7 0 256 1 256 1
```

Then those bins with amplitudes of 50% of the maximum or greater would be left unchanged, while those with amplitudes less than 50% of the maximum would be scaled down. In this case the lower the amplitude the more severe the scaling down would be. But suppose the score contains:

```
f2 0 512 5 1 512 .001
```

In this case lower amplitudes will be left unchanged and greater ones will be scaled down, turning the sound “upside-down” in terms of the amplitude spectrum! Functions can be arbitrarily complex. Just remember that the normalized amplitude values of the analysis are themselves the indeces into the function.

Finally, both spectral extraction and amplitude gating can be used together. The example below will synthesize only those components that with a frequency deviation of less than 5Hz per frame and it will scale the amplitudes according to f2.

```
asig  pvadd ktime, 1, "oboe.pvoc", 1, 100, 1, 1, 2, 5, 2
```

## USEFUL HINTS

By using several *pvadd* units together, one can gradually fade in different parts of the re-synthesis, creating various “filtering” effects. The author uses *pvadd* to synthesis one bin at a time to have control over each separate component of the re-synthesis.

If any combination of *ibins*, *ibinoffset*, and *ibinincr*, creates a situation where *pvadd* is asked to used a bin number greater than the number of bins in the analysis, it will just use all of the available bins, and give no complaint. So to use every bin just make *ibins* a big number (ie. 2000).

Expect to have to scale up the amplitudes by factors of 10-100, by the way.

Here is a complete example of the *pvadd* opcode. It uses the file *pvadd.csd* [examples/pvadd.csd]

# pbufread

pbufread — Reads from a phase vocoder analysis file and makes the retrieved data available.

## Description

*pbufread* reads from a *pvoc* file and makes the retrieved data available to any following *pvinterp* and *pvcross* units that appear in an instrument before a subsequent *pbufread* (just as *lpread* and *lpreson* work together). The data is passed internally and the unit has no output of its own.

## Syntax

```
pbufread ktmpnt, ifile
```

## Initialization

*ifile* -- the *pvoc* number (n in *pvoc.n*) or the name in quotes of the analysis file made using *pvalan*. (See *pvoc*.)

## Performance

*ktmpnt* -- the passage of time, in seconds, through this file. *ktmpnt* must always be positive, but can move forwards or backwards in time, be stationary or discontinuous, as a pointer into the analysis file.

## Examples

The example below shows an example using *pbufread* with *pvinterp* to interpolate between the sound of an oboe and the sound of a clarinet. The value of *kinterp* returned by a *linseg* is used to determine the timing of the transitions between the two sounds. The interpolation of frequencies and amplitudes are controlled by the same factor in this example, but for other effects it might be interesting to not have them synchronized in this way. In this example the sound will begin as a clarinet, transform into the oboe and then return again to the clarinet sound. The value of *kfreqscale2* is 1.065 because the oboe in this case is a semitone higher in pitch than the clarinet and this brings them approximately to the same pitch. The value of *kampscale2* is 0.75 because the analyzed clarinet was somewhat louder than the analyzed oboe. The setting of these two parameters make the transition quite smooth in this case, but such adjustments are by no means necessary or even advocated.

```
ktimel  line      0, p3, 3.5 ; used as index in the "oboe.pvoc" file
ktime2  line      0, p3, 4.5 ; used as index in the "clar.pvoc" file
kinterp linseg    1, p3*0.15, 1, p3*0.35, 0, p3*0.25, 0, p3*0.15, 1, p3*0.1, 1
          pbufread ktime1, "oboe.pvoc"
apv     pvinterp  ktime2,1,"clar.pvoc", 1, 1.065, 1, 0.75, 1-kinterp, 1-kinterp
```

Below is an example using *pbufread* with *pvcross*. In this example the amplitudes used in the resynthesis gradually change from those of the oboe to those of the clarinet. The frequencies, of course, remain those of the clarinet throughout the process since *pvcross* does not use the frequency data from the file read by *pbufread*.

```
ktimel  line      0, p3, 3.5 ; used as index in the "oboe.pvoc" file
ktime2  line      0, p3, 4.5 ; used as index in the "clar.pvoc" file
kcross   expon    0.001, p3, 1
          pbufread ktimel, "oboe.pvoc"
apv     pvcross   ktime2, 1, "clar.pvoc", 1-kcross, kcross
```

Here is a complete example of the `pbufread` opcode. It uses the file `pbufread.csd` [examples/pbufread.csd]

### Example 666. Example of the `pbufread` opcode.

## pvcross

`pvcross` — Applies the amplitudes from one phase vocoder analysis file to the data from a second file.

## Description

`pvcross` applies the amplitudes from one phase vocoder analysis file to the data from a second file and then performs the resynthesis. The data is passed, as described above, from a previously called `pbufread` unit. The two k-rate amplitude arguments are used to scale the amplitudes of each files separately before they are added together and used in the resynthesis (see below for further explanation). The frequencies of the first file are not used at all in this process. This unit simply allows for cross-synthesis through the application of the amplitudes of the spectra of one signal to the frequencies of a second signal. Unlike `pvinterp`, `pvcross` does allow for the use of the `ispecwp` as in `pvoc` and `vpvoc`.

## Syntax

```
ares pvcross ktimpnt, kfmod, ifile, kampscale1, kampscale2 [, ispecwp]
```

## Initialization

*ifile* -- the `pvoc` number (n in `pvoc.n`) or the name in quotes of the analysis file made using `pvalan`. (See `pvoc`.)

*ispecwp* (optional, default=0) -- if non-zero, attempts to preserve the spectral envelope while its frequency content is varied by *kfmod*. The default value is zero.

## Performance

*ktimpnt* -- the passage of time, in seconds, through this file. *ktimpnt* must always be positive, but can move forwards or backwards in time, be stationary or discontinuous, as a pointer into the analysis file.

*kfmod* -- a control-rate transposition factor: a value of 1 incurs no transposition, 1.5 transposes up a perfect fifth, and 0.5 down an octave.

*kampscale1*, *kampscale2* -- used to scale the amplitudes stored in each frame of the phase vocoder analysis file. *kampscale1* scale the amplitudes of the data from the file read by the previously called `pbufread`. *kampscale2* scale the amplitudes of the file named by *ifile*.

By using these arguments, it is possible to adjust these values before applying the interpolation. For example, if file1 is much louder than file2, it might be desirable to scale down the amplitudes of file1 or scale up those of file2 before interpolating. Likewise one can adjust the frequencies of each to bring them more in accord with one another (or just the opposite, of course!) before the interpolation is performed.

## Examples

Below is an example using `pbufread` with `pvcross`. In this example the amplitudes used in the resynthesis gradually change from those of the oboe to those of the clarinet. The frequencies, of course, remain those of the clarinet throughout the process since `pvcross` does not use the frequency data from the file read by `pbufread`.

```
ktimed1 line      0, p3, 3.5 ; used as index in the "oboe.pvoc" file
ktimed2 line      0, p3, 4.5 ; used as index in the "clar.pvoc" file
kcross expon    0.001, p3, 1
apv      pbufread ktime1, "oboe.pvoc"
          pvcross   ktime2, 1, "clar.pvoc", 1-kcross, kcross
```

Here is a complete example of the pvcross opcode. It uses the file *pvcross.csd* [examples/pvcross.csd]

# pvinterp

**pvinterp** — Interpolates between the amplitudes and frequencies of two phase vocoder analysis files.

## Description

*pvinterp* interpolates between the amplitudes and frequencies, on a bin by bin basis, of two phase vocoder analysis files (one from a previously called *pbufread* unit and the other from within its own argument list), allowing for user defined transitions between analyzed sounds. It also allows for general scaling of the amplitudes and frequencies of each file separately before the interpolated values are calculated and sent to the resynthesis routines. The *kfmod* argument in *pvinterp* performs its frequency scaling on the frequency values after their derivation from the separate scaling and subsequent interpolation is performed so that this acts as an overall scaling value of the new frequency components.

## Syntax

```
ares pvinterp ktimpnt, kfmod, ifile, kfreqscale1, kfreqscale2, \
      kampscale1, kampscale2, kfreqinterp, kampinterp
```

## Initialization

*ifile* -- the *pvoc* number (n in *pvoc.n*) or the name in quotes of the analysis file made using *pvaln*. (See *pvoc*.)

## Performance

*ktimpnt* -- the passage of time, in seconds, through this file. *ktimpnt* must always be positive, but can move forwards or backwards in time, be stationary or discontinuous, as a pointer into the analysis file.

*kfmod* -- a control-rate transposition factor: a value of 1 incurs no transposition, 1.5 transposes up a perfect fifth, and .5 down an octave.

*kfreqscale1*, *kfreqscale2*, *kampscale1*, *kampscale2* -- used in *pvinterp* to scale the frequencies and amplitudes stored in each frame of the phase vocoder analysis file. *kfreqscale1* and *kampscale1* scale the frequencies and amplitudes of the data from the file read by the previously called *pbufread* (this data is passed internally to the *pvinterp* unit). *kfreqscale2* and *kampscale2* scale the frequencies and amplitudes of the file named by *ifile* in the *pvinterp* argument list and read within the *pvinterp* unit.

By using these arguments, it is possible to adjust these values before applying the interpolation. For example, if file1 is much louder than file2, it might be desirable to scale down the amplitudes of file1 or scale up those of file2 before interpolating. Likewise one can adjust the frequencies of each to bring them more in accord with one another (or just the opposite, of course!) before the interpolation is performed.

*kfreqinterp*, *kampinterp* -- used in *pvinterp*, determine the interpolation distance between the values of one phase vocoder file and the values of a second file. When the value of *kfreqinterp* is 1, the frequency values will be entirely those from the first file (read by the *pbufread*), post scaling by the *kfreqscale1* argument. When the value of *kfreqinterp* is 0 the frequency values will be those of the second file (read by the *pvinterp* unit itself), post scaling by *kfreqscale2*. When *kfreqinterp* is between 0 and 1 the frequency values will be calculated, on a bin, by bin basis, as the percentage between each pair of frequencies (in other words, *kfreqinterp*=0.5 will cause the frequencies values to be half way between the values in the set of data from the first file and the set of data from the second file).

*kampinterp* works in the same way upon the amplitudes of the two files. Since these are k-rate arguments, the percentages can change over time making it possible to create many kinds of transitions between sounds.

## Examples

The example below shows an example using *pbufread* with *pvinterp* to interpolate between the sound of an oboe and the sound of a clarinet. The value of *kinterp* returned by a *linseg* is used to determine the timing of the transitions between the two sounds. The interpolation of frequencies and amplitudes are controlled by the same factor in this example, but for other effects it might be interesting to not have them synchronized in this way. In this example the sound will begin as a clarinet, transform into the oboe and then return again to the clarinet sound. The value of *kfreqscale2* is 1.065 because the oboe in this case is a semitone higher in pitch than the clarinet and this brings them approximately to the same pitch. The value of *kampscale2* is 0.75 because the analyzed clarinet was somewhat louder than the analyzed oboe. The setting of these two parameters make the transition quite smooth in this case, but such adjustments are by no means necessary or even advocated.

```
ktimel  line      0, p3, 3.5 ; used as index in the "oboe.pvoc" file
ktime2  line      0, p3, 4.5 ; used as index in the "clar.pvoc" file
kinterp linseg    1, p3*0.15, 1, p3*0.35, 0, p3*0.25, 0, p3*0.15, 1, p3*0.1, 1
        pbufread  ktimel, "oboe.pvoc"
apv     pvinterp  ktime2,1,"clar.pvoc", 1, 1.065, 1, 0.75, 1-kinterp, 1-kinterp
```

Here is a complete example of the *pvinterp* opcode. It uses the file *pvinterp.csd* [examples/pvinterp.csd]

# **pvoc**

**pvoc** — Implements signal reconstruction using an fft-based phase vocoder.

## **Description**

Implements signal reconstruction using an fft-based phase vocoder.

## **Syntax**

```
ares pvoc ktimpnt, kfmod, ifilcod [, ispecwp] [, iextractmode] \
[, ifreqlim] [, igatefn]
```

## **Initialization**

*ofilcod* -- integer or character-string denoting a control-file derived from analysis of an audio signal. An integer denotes the suffix of a file *pvoc.m*; a character-string (in double quotes) gives a filename, optionally a full pathname. If not fullpath, the file is sought first in the current directory, then in the one given by the environment variable *SADIR* (if defined). *pvoc* control contains breakpoint amplitude and frequency envelope values organized for fft resynthesis. Memory usage depends on the size of the files involved, which are read and held entirely in memory during computation but are shared by multiple calls (see also *lspread*).

*ispecwp* (optional) -- if non-zero, attempts to preserve the spectral envelope while its frequency content is varied by *kfmod*. The default value is zero.

*iextractmode* (optional) -- determines if spectral extraction will be carried out and if so whether components that have changes in frequency below *ifreqlim* or above *ifreqlim* will be discarded. A value for *iextractmode* of 1 will cause *pvoc* to synthesize only those components where the frequency difference between analysis frames is greater than *ifreqlim*. A value of 2 for *iextractmode* will cause *pvoc* to synthesize only those components where the frequency difference between frames is less than *ifreqlim*. The default values for *iextractmode* and *ifreqlim* are 0, in which case a simple resynthesis will be done. See examples under *pvadd* for how to use spectral extraction.

*igatefn* (optional) -- the number of a stored function which will be applied to the amplitudes of the analysis bins before resynthesis takes place. If *igatefn* is greater than 0 the amplitudes of each bin will be scaled by *igatefn* through a simple mapping process. First, the amplitudes of all of the bins in all of the frames in the entire analysis file are compared to determine the maximum amplitude value. This value is then used to create normalized amplitudes as indices into the stored function *igatefn*. The maximum amplitude will map to the last point in the function. An amplitude of 0 will map to the first point in the function. Values between 0 and 1 will map accordingly to points along the function table. See examples under *pvadd* for how to use amplitude gating.

## **Performance**

*ktimpnt* -- The passage of time, in seconds, through the analysis file. *ktimpnt* must always be positive, but can move forwards or backwards in time, be stationary or discontinuous, as a pointer into the analysis file.

*kfmod* -- a control-rate transposition factor: a value of 1 incurs no transposition, 1.5 transposes up a perfect fifth, and .5 down an octave.

*pvoc* implements signal reconstruction using an fft-based phase vocoder. The control data stems from a

precomputed analysis file with a known frame rate.

This implementation of *pvoc* was originally written by Dan Ellis. It is based in part on the system of Mark Dolson, but the pre-analysis concept is new. The spectral extraction and amplitude gating (new in Csound version 3.56) were added by Richard Karpen based on functions in SoundHack by Tom Erbe.

## Examples

Here is an example of the *pvoc* opcode. It uses the file *pvoc.csd* [examples/pvoc.csd].

### Example 669. Example of the *pvoc* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pvread

**pvread** — Reads from a phase vocoder analysis file and returns the frequency and amplitude from a single analysis channel or bin.

## Description

**pvread** reads from a *pvoc* file and returns the frequency and amplitude from a single analysis channel or bin. The returned values can be used anywhere else in the Csound instrument. For example, one can use them as arguments to an oscillator to synthesize a single component from an analyzed signal or a bank of *pvreads* can be used to resynthesize the analyzed sound using additive synthesis by passing the frequency and magnitude values to a bank of oscillators.

## Syntax

```
kfreq, kamp pvread ktimpnt, ifile, ibin
```

## Initialization

*ifile* -- the *pvoc* number (n in *pvoc.n*) or the name in quotes of the analysis file made using *pvanal*. (See *pvoc*.)

*ibin* -- the number of the analysis channel from which to return frequency in Hz and magnitude.

## Performance

*kfreq*, *kamp* -- outputs of the *pvread* unit. These values, retrieved from a phase vocoder analysis file, represent the values of frequency and amplitude from a single analysis channel specified in the *ibin* argument. Interpolation between analysis frames is performed at k-rate resolution and dependent of course upon the rate and direction of *ktimpnt*.

*ktimpnt* -- the passage of time, in seconds, through this file. *ktimpnt* must always be positive, but can move forwards or backwards in time, be stationary or discontinuous, as a pointer into the analysis file.

## Examples

The example below shows the use *pvread* to synthesize a single component at a time from a phase vocoder analysis file. It should be noted that the *kfreq* and *kamp* outputs can be used for any kind of synthesis, filtering, processing, and so on.

### Example 670. Example of the *pvread* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pvsadsyn

pvsadsyn — Resynthesize using a fast oscillator-bank.

## Description

Resynthesize using a fast oscillator-bank.

## Syntax

```
ares pvsadsyn fsrc, inoscs, kfmod [, ibinoffset] [, ibinincr] [, iinit]
```

## Initialization

*inoscs* -- The number of analysis bins to synthesize. Cannot be larger than the size of fsrc (see *pvsinfo*), e.g. as created by *pvsanal*. Processing time is directly proportional to inoscs.

*ibinoffset* (optional, default=0) -- The first (lowest) bin to resynthesize, counting from 0 (default = 0).

*ibinincr* (optional) -- Starting from bin *ibinoffset*, resynthesize bins *ibinincr* apart.

*iinit* (optional) -- Skip reinitialization. This is not currently implemented for any of these opcodes, and it remains to be seen if it is even practical.

## Performance

*kfmod* -- Scale all frequencies by factor *kfmod*. 1.0 = no change, 2 = up one octave.

*pvsadsyn* is experimental, and implements the oscillator bank using a fast direct calculation method, rather than a lookup table. This takes advantage of the fact, empirically arrived at, that for the analysis rates generally used, (and presuming analysis using *pvsanal*, where frequencies in a bin change only slightly between frames) it is not necessary to interpolate frequencies between frames, only amplitudes. Accurate resynthesis is often contingent on the use of *pvsanal* with *iwinsize* = *ifftsize*\*2.

This opcode is the most likely to change, or be much extended, according to feedback and advice from users. It is likely that a full interpolating table-based method will be added, via a further optional *iarg*. The parameter list to *pvsadsyn* mimics that for *pvadd*, but excludes spectral extraction.

## Examples

Here is an example of the *pvsadsyn* opcode. It uses the file *pvsadsyn.csd* [examples/pvsadsyn.csd].

### Example 671. Example of the pvsadsyn opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pvsanal

pvsanal — Generate an fsig from a mono audio source ain, using phase vocoder overlap-add analysis.

## Description

Generate an fsig from a mono audio source ain, using phase vocoder overlap-add analysis.

## Syntax

```
fsig pvsanal ain, ifftsize, ioverlap, iwinsize, iwintype [, iformat] [, iinit]
```

## Initialization

*ifftsize* -- The FFT size in samples. Need not be a power of two (though these are especially efficient), but must be even. Odd numbers are rounded up internally. *ifftsize* determines the number of analysis bins in *fsig*, as *ifftsize*/2 + 1. For example, where *ifftsize* = 1024, *fsig* will contain 513 analysis bins, ordered linearly from the fundamental to Nyquist. The fundamental of analysis (which in principle gives the lowest resolvable frequency) is determined as *sr/ifftsize*. Thus, for the example just given and assuming *sr* = 44100, the fundamental of analysis is 43.07Hz. In practice, due to the phase-preserving nature of the phase vocoder, the frequency of any bin can deviate bilaterally, so that DC components are recorded. Given a strongly pitched signal, frequencies in adjacent bins can bunch very closely together, around partials in the source, and the lowest bins may even have negative frequencies.

As a rule, the only reason to use a non power-of-two value for *ifftsize* would be to match the known fundamental frequency of a strongly pitched source. Values with many small factors can be almost as efficient as power-of-two sizes; for example: 384, for a source pitched at around low A=110Hz.

*ioverlap* -- The distance in samples (“hop size”) between overlapping analysis frames. As a rule, this needs to be at least *ifftsize*/4, e.g. 256 for the example above. *ioverlap* determines the underlying analysis rate, as *sr/overlap*. *ioverlap* does not require to be a simple factor of *ifftsize*; for example a value of 160 would be legal. The choice of *ioverlap* may be dictated by the degree of pitch modification applied to the *fsig*, if any. As a rule of thumb, the more extreme the pitch shift, the higher the analysis rate needs to be, and hence the smaller the value for *ioverlap*. A higher analysis rate can also be advantageous with broadband transient sounds, such as drums (where a small analysis window gives less smearing, but more frequency-related errors).

Note that it is possible, and reasonable, to have distinct fsigs in an orchestra (even in the same instrument), running at different analysis rates. Interactions between such fsigs is currently unsupported, and the fsig assignment opcode does not allow copying between fsigs with different properties, even if the only difference is in *ioverlap*. However, this is not a closed issue, as it is possible in theory to achieve crude rate conversion (especially with regard to in-memory analysis files) in ways analogous to time-domain techniques.

*iwinsize* -- The size in samples of the analysis window filter (as set by *iwintype*). This must be at least *ifftsize*, and can usefully be larger. Though other proportions are permitted, it is recommended that *iwinsize* always be an integral multiple of *ifftsize*, e.g. 2048 for the example above. Internally, the analysis window (Hamming, von Hann) is multiplied by a sinc function, so that amplitudes are zero at the boundaries between frames. The larger analysis window size has been found to be especially important for oscillator bank resynthesis (e.g. using *pvsadsyn*), as it has the effect of increasing the frequency resolution of the analysis, and hence the accuracy of the resynthesis. As noted above, *iwinsize* determines the overall latency of the analysis/resynthesis system. In many cases, and especially in the absence of pitch modifications, it will be found that setting *iwinsize*=*ifftsize* works very well, and offers the lowest

latency.

*iwintype* -- The shape of the analysis window. Currently only two choices are implemented:

- 0 = Hamming window
- 1 = von Hann window

Both are also supported by the PVOC-EX file format. The window type is stored as an internal attribute of the fsig, together with the other parameters (see *pvsinfo*). Other types may be implemented later on (e.g. the Kaiser window, also supported by PVOC-EX), though an obvious alternative is to enable windows to be defined via a function table. The main issue here is the constraint of f-tables to power-of-two sizes, so this method does not offer a complete solution. Most users will find the Hamming window meets all normal needs, and can be regarded as the default choice.

*iformat* -- (optional) The analysis format. Currently only one format is implemented by this opcode:

- 0 = amplitude + frequency

This is the classic phase vocoder format; easy to process, and a natural format for oscillator-bank resynthesis. It would be very easy (tempting, one might say) to treat an fsig frame not purely as a phase vocoder frame but as a generic additive synthesis frame. It is indeed possible to use an fsig this way, but it is important to bear in mind that the two are not, strictly speaking, directly equivalent.

Other important formats (supported by PVOC-EX) are:

- 1 = amplitude + phase
- 2 = complex (real + imaginary)

*iformat* is provided in case it proves useful later to add support for these other formats. Formats 0 and 1 are very closely related (as the phase is “wrapped” in both cases - it is a trivial matter to convert from one to the other), but the complex format might warrant a second explicit signal type (a “csig”) specifically for convolution-based processes, and other processes where the full complement of arithmetic operators may be useful.

*iinit* -- (optional) Skip reinitialization. This is not currently implemented for any of these opcodes, and it remains to be seen if it is even practical.

## Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

Here is an example of the pvsanal opcode. It uses the file *pvsanal.csd* [examples/pvsanal.csd].

# pvsarp

pvsarp — Arpeggiate the spectral components of a streaming pv signal.

## Description

This opcode arpeggiates spectral components, by amplifying one bin and attenuating all the others around it. Used with an LFO it will provide a spectral arpeggiator similar to Trevor Wishart's CDP program specarp.

## Syntax

```
fsig pvsarp fsigin, kbin, kdepth, kgain
```

## Performance

*fsig* -- output pv stream

*fsigin* -- input pv stream

*kbin* -- target bin, normalised 0 - 1 (0Hz - Nyquist).

*kdepth* -- depth of attenuation of surrounding bins

*kgain* -- gain boost applied to target bin

### Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

Here is an example of the pvsarp opcode. It uses the file *pvsarp.csd* [examples/pvsarp.csd]

# pvsbandp

pvsbandp — A band pass filter working in the spectral domain.

## Description

Filter the pvoc frames, passing bins whose frequency is within a band, and with linear interpolation for transitional bands.

## Syntax

```
fsig pvsbandp fsigin, xlowcut, xlowfull, \
      xhighfull, xhighcut[, ktype]
```

## Performance

*fsig* -- output pv stream

*fsigin* -- input pv stream.

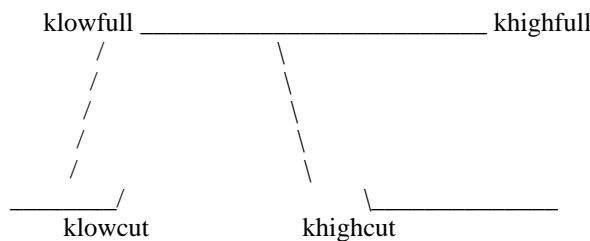

*xlowcut*, *xlowfull*, *xhighfull*, *xhighcut* -- define a trapezium shape for the band that is passed. The a-rate versions only apply to the sliding case.

*ktype* -- specifies the shape of the transitional band. If at the default value of zero the shape is as below, with linear transition in amplitude. Other values yield and exponential shape:

$$(1 - \exp(r * type)) / (1 - \exp(type))$$

This includes a linear dB shape when *ktype* is *log(10)* or about 2.30.

The opcode performs a band-pass filter with a spectral envelope shaped like

## Examples

# pvsbandr

pvsbandr — A band reject filter working in the spectral domain.

## Description

Filter the pvoc frames, rejecting bins whose frequency is within a band, and with linear interpolation for transitional bands.

## Syntax

```
fsig pvsbandr fsigin, xlowcut, xlowfull, \
      xhighfull, xhighcut[, ktype]
```

## Performance

*fsig* -- output pv stream

*fsigin* -- input pv stream.

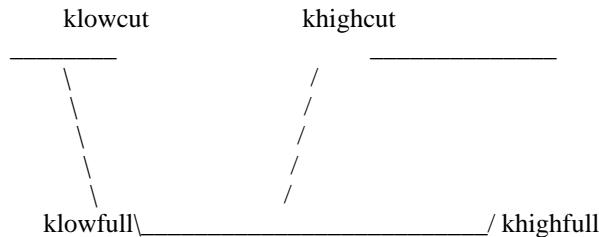

*xlowcut*, *xlowfull*, *xhighfull*, *xhighcut* -- define a trapezium shape for the band that is rejected. The a-rate versions only apply to the sliding case.

*ktype* -- specifies the shape of the transitional band. If at the default value of zero the shape is as below, with linear transition in amplitude. Other values give an exponential curve

$$(1 - \exp(-r * type)) / (1 - \exp(type))$$

This includes a linear dB shape when *ktype* is *log(10)* or about 2.30.

The opcode performs a band-reject filter with a spectral envelope shaped like

## Examples

Here is an example of the pvsbandr opcode. It uses the file *pvsbandr.csd* [examples/pvsbandr.csd].

### Example 676. Example of the pvsbandr opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pvsbin

pvsbin — Obtain the amp and freq values off a PVS signal bin.

## Description

Obtain the amp and freq values off a PVS signal bin as k-rate variables.

## Syntax

```
kamp, kfr pvsbin fsig, kbin
```

## Performance

*kamp* -- bin amplitude

*kfr* -- bin frequency

*fsig* -- an input pv stream

*kbin* -- bin number

## Examples

Here is an example of the pvsbin opcode. It uses the file *pvsbin.csd* [examples/pvsbin.csd]. This example uses realtime input, but you can also use it for soundfile input.

### Example 677. Example of the pvsbin opcode

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pvsblur

pvsblur — Average the amp/freq time functions of each analysis channel for a specified time.

## Description

Average the amp/freq time functions of each analysis channel for a specified time (truncated to number of frames). As a side-effect the input pvoc stream will be delayed by that amount.

## Syntax

```
fsig pvsblur fsigin, kblurttime, imaxdel
```

## Performance

*fsig* -- output pv stream

*fsigin* -- input pv stream.

*kblurttime* -- time in secs during which windows will be averaged .

*imaxdel* -- maximum delay time, used for allocating memory used in the averaging operation.

This opcode will blur a pvstream by smoothing the amplitude and frequency time functions (a type of low-pass filtering); the amount of blur will depend on the length of the averaging period, larger blur-times will result in a more pronounced effect.

### Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

Here is an example of the use of the *pvsblur* opcode. It uses the file *pvsblur.csd* [examples/pvsblur.csd].

### Example 678. Example of the *pvsblur* opcode.

# pvsbuffer

*pvsbuffer* — This opcode creates and writes to a circular buffer for f-signals (streaming PV signals).

## Description

This opcode sets up and writes to a circular buffer of length *ilen* (secs), giving a handle for the buffer and a time pointer, which holds the current write position (also in seconds). It can be used with one or more *pvsbufread* opcodes. Writing is circular, wrapping around at the end of the buffer.

## Syntax

```
ihandle, ktime  pvsbuffer fsig, ilen
```

## Initialisation

### Initialisation

*ihandle* -- handle identifying this particular buffer, which should be passed to a reader opcode.

*ilen* -- buffer length in seconds.

*fsig* -- an input pv stream

*ktime* -- the current time of writing in the buffer

*pvsbuffer* stores *fsig* in a buffer which can be read by *pvsbufread* using the handle *ihandle*. Different buffers will have different handles so they can be read independently by different *pvsbufread* opcodes. *pvsbuffer* gives in its output the current time (*ktime*) inside the ring buffer which has just been written.

## Examples

See *pvsbufread* for examples of the pvsbuffer opcode.

# pvsbufread

pvsbufread — This opcode reads a circular buffer of f-signals (streaming PV signals).

## Description

This opcode reads from a circular buffer of length *ilen* (secs), taking a handle for the buffer and a time pointer, which holds the current read position (also in seconds). It is used in conjunction with a *pvsbuffer* opcode. Reading is circular, wrapping around at the end of the buffer.

## Syntax

```
fsig pvsbufread ktime, khandle[, ilo, ihi, iclear]
```

## Initialisation

*ilo, ihi* -- set the lowest and highest freqs to be read from the buffer (defaults to 0, Nyquist).

*iclear* -- set to 1 to clear output *fsig* before every write (default 1), 0 tells the opcode not to clear the output *fsig*. This is relevant when writing to subsets of an *fsig* frame using *ilo, ihi*.

## Performance

*fsig* -- output pv stream

*ktime* -- time position of reading pointer (in secs).

*khandle* -- handle identifying the buffer to be read. When using k-rate handles, it is important to initialise the k-rate variable to a given existing handle. When changing buffers, *fsig* buffers need to be compatible (same *fsig* format).

With this opcode and *pvsbuffer*, it is possible to, among other things:

- time-stretch/compress a *fsig* stream, by reading it at different rates
- delay a *fsig* or portions of it.
- 'brassage' two or more *fsigs* by switching buffers, since the reading handles are k-rate. Note that, when using k-rate handles, it is important to initialise the k-rate variable to a given handle (so that the *fsig* initialisation can take place) and it is only possible to switch handles between compatible *fsig* buffers (with the same fftsize and overlap).

### Note

It is important that the handle value passed to *pvsbufread* is valid and was created by *pvsbuffer*. Csound will crash with invalid handles.

## Examples

Here is an example of the pvsbufread opcode. It does 'brassage' by switching between two buffers.

### Example 679. Example of the pvsbufread opcode

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
fsig1      pvsanal    asig1, 1024, 256, 1024, 1
fsig2      pvsanal    asig2, 1024, 256, 1024, 1

ibuf1, kt1 pvsbuffer fsig1, 10 ; 10-sec buf with fsig1
ibuf2, kt2 pvsbuffer fsig2, 7   ; 7-sec buf with fsig2

khan       init       ibuf1      ; initialise handle to buf1
if ktrig > 0 then           ; switch buffers according to trigger
khan = ibuf2
else
khan = ibuf1
endif

fsb        pvsbufread kt1, khan ; read buffer
```

Here is an example of the pvsbufread opcode. It uses the file *pvsbufread.csd* [examples/pvsbufread.csd].

### Example 680. Example of the pvsbufread opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pvsbufread2

pvsbufread2 — This opcode reads a circular buffer of f-signals (streaming PV signals), with binwise additional delays.

## Description

This opcode reads from a circular buffer of length ilen (secs), taking a handle for the buffer and a time pointer, which holds the current read position (also in seconds). It is used in conjunction with a *pvsbuffer* opcode. Reading is circular, wrapping around at the end of the buffer. Extra delay times are taken from a function table, with each point on it defining a delay time in seconds affecting the corresponding bin.

## Syntax

```
fsig pvsbufread2 ktime, khandle, ift1, ift2
```

## Initialization

*ift1* -- function table with at least fftisze/2+1 points where delays (in secs) for bin amplitudes are set (function table positions are equivalent to bin numbers)

*ift2* -- function table with at least fftisze/2+1 points where delays (in secs) for bin frequencies are set (function table positions are equivalent to bin numbers)

## Performance

*fsig* -- output pv stream

*ktime* -- time position of reading pointer (in secs).

*khandle* -- handle identifying the buffer to be read. When using k-rate handles, it is important to initialise the k-rate variable to a given existing handle. When changing buffers, fsig buffers need to be compatible (same fsig format).

With this opcode and *pvsbuffer*, it is possible to, among other things:

- time-stretch/compress a fsig stream, by reading it at different rates
- delay a fsig or portions of it.
- 'brassage' two or more fsigs by switching buffers, since the reading handles are k-rate. Note that, when using k-rate handles, it is important to initialise the k-rate variable to a given handle (so that the fsig initialisation can take place) and it is only possible to switch handles between compatible fsig buffers (with the same fftsize and overlap).

### Note

It is important that the handle value passed to *pvsbufread2* is valid and was created by *pvsbuffer*. Csound will crash with invalid handles.

## Examples

Here is an example of the pvsbufread2 opcode. It uses the file *pvsbufread2.csd* [examples/pvsbufread2.csd].

### Example 681. Example of the pvsbufread2 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pvscale

pvscale — Scale the frequency components of a pv stream.

## Description

Scale the frequency components of a pv stream, resulting in pitch shift. Output amplitudes can be optionally modified in order to attempt formant preservation.

## Syntax

```
fsig pvscale fsigin, kscal[, kkeepform, kgain, kcoefs]
```

## Performance

*fsig* -- output pv stream

*fsigin* -- input pv stream

*kscal* -- scaling ratio.

*kkeepform* -- attempt to keep input signal formants; 0: do not keep formants; 1: keep formants using a liftered cepstrum method; 2: keep formants by using a true envelope method (defaults to 0).

*kgain* -- amplitude scaling (defaults to 1).

*kcoefs* -- number of cepstrum coefs used in formant preservation (defaults to 80).

The quality of the pitch shift will be improved with the use of a Hanning window in the pvoc analysis. Formant preservation method 1 is less intensive than method 2, which might not be suited to realtime use.

## Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

### Example 682. Example

```
asig  in                               ; get the signal in
      fsig  pvsanal  asig, 1024, 256, 1024, 1 ; analyse it
      ftps  pvscale  fsig, 1.5, 1, 1        ; transpose it keeping formants
      atps  pvsynth  ftps                  ; synthesise it
      adp   delayr   0.1                   ; delay original signal
      adel  deltapn  1024                 ; by 1024 samples
      delayw  asig
```

```
out      atps + adel           ; add tranposed and original
```

The example above shows a vocal harmoniser. The delay is necessary to time-align the signals, as the analysis-synthesis process will imply a delay of 1024 samples between the analysis input and the synthesis output.

Here is an example of the use of the *pvscale* opcode. It uses the file *pvscale.csd* [examples/pvscale.csd].

### Example 683. Example of the *pvscale* opcode.

# pvscross

pvscross — Performs cross-synthesis between two source fsigs.

## Description

Performs cross-synthesis between two source fsigs.

## Syntax

```
fsig pvscross fsrc, fdest, kamp1, kamp2
```

## Performance

The operation of this opcode is identical to that of *pvcross* (q.v.), except in using *fsigs* rather than analysis files, and the absence of spectral envelope preservation. The amplitudes from *fsrc* and *fdest* (using scale factors *kamp1* for *fsrc* and *kamp2* for *fdest*) are applied to the frequencies of *fsrc*. *kamp1* and *kamp2* must not exceed the range 0 to 1.

With this opcode, cross-synthesis can be performed on real-time audio input, by using *pvsanal* to generate *fsrc* and *fdest*. These must have the same format.

### Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

Here is an example of the use of the *pvscross* opcode. It uses the file *pvscross.csd* [examples/*pvscross.csd*].

### Example 685. Example of the *pvscross* opcode.

# pvsdemix

pvsdemix — Spectral azimuth-based de-mixing of stereo sources.

## Description

Spectral azimuth-based de-mixing of stereo sources, with a reverse-panning result. This opcode implements the Azimuth Discrimination and Resynthesis (ADResS) algorithm, developed by Dan Barry (Barry et Al. "Sound Source Separation Azimuth Discrimination and Resynthesis". DAFX'04, Univ. of Napoli). The source separation, or de-mixing, is controlled by two parameters: an azimuth position (*kpos*) and a subspace width (*kwidth*). The first one is used to locate the spectral peaks of individual sources on a stereo mix, whereas the second widens the 'search space', including/excluding the peaks around *kpos*. These two parameters can be used interactively to extract source sounds from a stereo mix. The algorithm is particularly successful with studio recordings where individual instruments occupy individual panning positions; it is, in fact, a reverse-panning algorithm.

### Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Syntax

```
fsig pvsdemix fleft, fright, kpos, kwidth, ipoints
```

## Performance

*fsig* -- output pv stream

*fleft* -- left channel input pv stream.

*fright* -- right channel pv stream.

*kpos* -- the azimuth target centre position, which will be de-mixed, from left to right (-1 <= *kpos* <= 1). This is the reverse pan-pot control.

*kwidth* -- the azimuth subspace width, which will determine the number of points around *kpos* which will be used in the de-mixing process. (1 <= *kwidth* <= *ipoints*)

*ipoints* -- total number of discrete points, which will divide each pan side of the stereo image. This ultimately affects the resolution of the process.

## Examples

The example below takes a stereo input and passes through a de-mixing process revealing a source located at *ipos* +/- *iwidth* points. These parameters can be controlled in realtime (e.g. using FLTK widgets or MIDI) for an interactive search of sound sources.

### Example 686. Example

```
ifftsize = 1024      /* cleaner with hanning window      */
iwtype   = 1          /* to the left of the stereo image  */
ipos     = -0.8       /* use peaks of 20 points around it */
iwidth   = 20         /* */

al,ar  soundin    "sinput.wav"

flc   pvsanal    al, ifftsize, ifftsize/4, ifftsize, iwtype
frc   pvsanal    ar, ifftsize, ifftsize/4, ifftsize, iwtype
fdm   pvsdemix   flc, frc, kpos, kwidth, 100
adm   pvsynth    fdm

# pvsdiskin

pvsdiskin — Read a selected channel from a PVOC-EX analysis file.

## Description

Create an fsig stream by reading a selected channel from a PVOC-EX analysis file, with frame interpolation.

## Syntax

```
fsig pvsdiskin SFname,ktscal,kgain[,ioffset, ichan]
```

## Initialization

*Sfname* -- Name of the analysis file. This must have the .pxv file extension.

A multi-channel PVOC-EX file can be generated using the extended *pvanal utility*.

*ichan* -- (optional) The channel to read (counting from 1). Default is 1.

*ioff* -- start offset from beginning of file (secs) (default: 0) .

## Performance

*ktscal* -- time scale, ie. the read pointer speed (1 is normal speed, negative is backwards,  $0 < \text{ktscal} < 1$  is slower and  $\text{ktscal} > 1$  is faster)

*kgain* -- gain scaling.

## Examples

Here is an example of the pvsdiskin opcode. It uses the file *pvsdiskin.csd* [examples/pvsdiskin.csd].

### Example 687. Example of the pvsdiskin opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pvsdisp

pvsdisp — Displays a PVS signal as an amplitude vs. freq graph.

## Description

This opcode will display a PVS signal fsig. Uses X11 or FLTK windows if enabled, else (or if -g flag is set) displays are approximated in ASCII characters.

## Syntax

```
pvsdisp fsig[, ibins, iwtflg]
```

## Initialization

*iprd* -- the period of pvsdisp in seconds.

*ibins* (optional, default=all bins) -- optionally, display only *ibins* bins.

*iwtflg* (optional, default=0) -- wait flag. If non-zero, each pvsdisp is held until released by the user. The default value is 0 (no wait).

## Performance

*pvsdisp* -- displays the PVS signal frame-by-frame.

## Examples

Here is an example of the pvsdisp opcode. It uses the file *pvsdisp.csd* [examples/pvsdisp.csd]. This example uses realtime input, but you can also use it for soundfile input.

### Example 688. Example of the pvsdisp opcode

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out    Audio in
-o dac          -iadc    ;;;RT audio I/O

# pvsfilter

pvsfilter — Multiply amplitudes of a pvoc stream by those of a second pvoc stream, with dynamic scaling.

## Description

Multiply amplitudes of a pvoc stream by those of a second pvoc stream, with dynamic scaling.

## Syntax

```
fsig pvsfilter fsigin, fsigfil, kdepth[, igain]
```

## Performance

*fsig* -- output pv stream

*fsigin* -- input pv stream.

*fsigfil* -- filtering pvoc stream.

*kdepth* -- controls the depth of filtering of *fsigin* by *fsigfil*.

*igain* -- amplitude scaling (optional, defaults to 1).

Here the input pvoc stream amplitudes are modified by the filtering stream, keeping its frequencies intact. As usual, both signals have to be in the same format.

### Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

### Example 689. Example

```
kfreq expon 500, p3, 4000      ; 3-octave sweep
kdepth linseg 1, p3/2, 0.5, p3/2, 1 ; varying filter depth

asig in
afil oscili 1, kfreq, 1          ; input
                                  ; filter t-domain signal

fim pvsanal asig,1024,256,1024,0 ; pvoc analysis
fil pvsanal afil,1024,256,1024,0
fou pvsfilter fim, fil, kdepth   ; filter signal
aout pvsynth fou                ; pvoc synthesis
```

In the example above the filter curve will depend on the spectral envelope of afil; in the simple case of a sinusoid, it will be equivalent to a narrowband band-pass filter.

Here is an example of the use of the *pvsfilter* opcode. It uses the file *pvsfilter.csd* [examples/pvsfilter.csd].

### Example 690. Example of the *pvsfilter* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pvsfread

pvsfread — Read a selected channel from a PVOC-EX analysis file.

## Description

Create an fsig stream by reading a selected channel from a PVOC-EX analysis file loaded into memory, with frame interpolation. Only format 0 files (amplitude+frequency) are currently supported. The operation of this opcode mirrors that of pvoc, but outputs an fsig instead of a resynthesized signal.

## Syntax

```
fsig pvsfread ktimpt, ifn [, ichan]
```

## Initialization

*ifn* -- Name of the analysis file. This must have the .pxx file extension.

A multi-channel PVOC-EX file can be generated using the extended *pvanal utility*.

*ichan* -- (optional) The channel to read (counting from 0). Default is 0.

## Performance

*ktimpt* -- Time pointer into analysis file, in seconds. See the description of the same parameter of *pvoc* for usage.

Note that analysis files can be very large, especially if multi-channel. Reading such files into memory will very likely incur breaks in the audio during real-time performance. As the file is read only once, and is then available to all other interested opcodes, it can be expedient to arrange for a dedicated instrument to preload all such analysis files at startup.

## Examples

Here is an example of the pvsfread opcode. It uses the file *pvsfread.csd* [examples/pvsfread.csd].

### Example 691. Example of the pvsfread opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>

# pvsfreeze

pvsfreeze — Freeze the amplitude and frequency time functions of a pv stream according to a control-rate trigger.

## Description

This opcodes 'freezes' the evolution of pvs stream by locking into steady amplitude and/or frequency values for each bin. The freezing is controlled, independently for amplitudes and frequencies, by a control-rate trigger, which switches the freezing 'on' if equal to or above 1 and 'off' if below 1.

## Syntax

```
fsig pvsfreeze fsigin, kfreeza, kfreezf
```

## Performance

*fsig* -- output pv stream

*fsigin* -- input pv stream.

*kfreeza* -- freezing switch for amplitudes. Freezing is on if above or equal to 1 and off if below 1.

*kfcf* -- freezing switch for frequencies. Freezing is on if above or equal to 1 and off if below 1.

### Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

### Example 692. Example

```
asig  in
ktrig oscil    1.5, 0.25, 1          ; input
fim   pvsanal  asig1, 1024, 256, 1024, 0 ; trigger
fou   pvsfreeze fim, abs(ktrig), abs(ktrig) ; pvoc analysis
aout  pvsynth  fou                   ; regular 'freeze' of spectra
                                         ; pvoc synthesis
```

In the example above the input signal will be regularly 'frozen' for a short while, as the trigger rises above 1 about every two seconds.

Here is an example of the use of the *pvsfreeze* opcode. It uses the file *pvsfreeze.csd* [examples/pvsfreeze.csd].

**Example 693. Example of the *pvsfreeze* opcode.**

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pvsftr

pvsftr — Reads amplitude and/or frequency data from function tables.

## Description

Reads amplitude and/or frequency data from function tables.

## Syntax

```
pvsftr fsrc, ifna [, ifnf]
```

## Initialization

*ifna* -- A table, at least inbins in size, that stores amplitude data. Ignored if *ifna* = 0

*ifnf* (optional) -- A table, at least inbins in size, that stores frequency data. Ignored if *ifnf* = 0

## Performance

*fsrc* -- a PVOC-EX formatted source.

Enables the contents of *fsrc* to be exchanged with function tables for custom processing. Except when the frame overlap equals *ksmps* (which will generally not be the case), the frame data is not updated each control period. The data in *ifna*, *ifnf* should only be processed when *kflag* is set to 1. To process only frequency data, set *ifna* to zero.

As the function tables are required only to store data from *fsrc*, there is no advantage in defining them in the score, and they should generally be created in the instrument, using *fgen*.

By exporting amplitude data, say, from one fsig and importing it into another, basic cross-synthesis (as in *pvcross*) can be performed, with the option to modify the data beforehand using the table manipulation opodes.

Note that the format data in the source fsig is not written to the tables. This therefore offers a means of transferring amplitude and frequency data between non-identical fsigs. Used this way, these opcodes become potentially pathological, and can be relied upon to produce unexpected results. In such cases, resynthesis using *pvsadsyn* would almost certainly be required.

To perform a straight copy from one fsig to another one of identical format, the conventional assignment syntax can be used:

```
fsig1 = fsig2
```

It is not necessary to use function tables in this case.

## Examples

Here is an example of the pvsftr opcode. It uses the file *pvsftr.csd* [examples/pvsftr.csd].

### Example 694. Example of the pvsftr opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pvsftw

pvsftw — Writes amplitude and/or frequency data to function tables.

## Description

Writes amplitude and/or frequency data to function tables.

## Syntax

```
kflag pvsftw fsrc, ifna [, ifnf]
```

## Initialization

*ifna* -- A table, at least inbins in size, that stores amplitude data. Ignored if ifna = 0

*ifnf* -- A table, at least inbins in size, that stores frequency data. Ignored if ifnf = 0

## Performance

*kflag* -- A flag that has the value of 1 when new data is available, 0 otherwise.

*fsrc* -- a PVOC-EX formatted source.

Enables the contents of *fsrc* to be exchanged with function tables, for custom processing. Except when the frame overlap equals *ksmps* (which will generally not be the case), the frame data is not updated each control period. The data in *ifna*, *ifnf* should only be processed when *kflag* is set to 1. To process only frequency data, set *ifna* to zero.

As the functions tables are required only to store data from *fsrc*, there is no advantage in defining them in the score. They should generally be created in the instrument using *ftgen*.

By exporting amplitude data, say, from one fsig and importing it into another, basic cross-synthesis (as in *pvcross*) can be performed, with the option to modify the data beforehand using the table manipulation opodes.

Note that the format data in the source fsig is not written to the tables. This therefore offers a means of transferring amplitude and frequency data between non-identical fsigs. Used this way, these opcodes become potentially pathological, and can be relied upon to produce unexpected results. In such cases, resynthesis using *pvsadsyn* would almost certainly be required.

To perform a straight copy from one fsig to another one of identical format, the conventional assignment syntax can be used:

```
fsig1 = fsig2
```

It is not necessary to use function tables in this case.

# pvsgain

`pvsgain` — Scale the amplitude of a pv stream.

## Description

Scale the amplitude of a pv stream.

## Syntax

```
fsig pvsgain fsigin, kgain
```

## Performance

*fsig* -- output pv stream

*fsigin* -- input pv stream

*kgain* -- amplitude scaling (defaults to 1).

### Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

Here is an example of the use of the `pvsgain` opcode. It uses the file `pvsgain.csd` [examples/pvsgain.csd].

### Example 697. Example of the `pvsgain` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pvshift

pvshift — Shift the frequency components of a pv stream, stretching/compressing its spectrum.

## Description

Shift the frequency components of a pv stream, stretching/compressing its spectrum.

## Syntax

```
fsig pvshift fsigin, kshift, klowest[, kkeepform, igain, kcoefs]
```

## Performance

*fsig* -- output pv stream

*fsigin* -- input pv stream

*kshift* -- shift amount (in Hz, positive or negative).

*klowest* -- lowest frequency to be shifted.

*kkeepform* -- attempt to keep input signal formants; 0: do not keep formants; 1: keep formants using a liftered cepstrum method; 2: keep formants by using a true envelope method (defaults to 0).

*kgain* -- amplitude scaling (defaults to 1).

*kcoefs* -- number of cepstrum coeffs used in formant preservation (defaults to 80).

This opcode will shift the components of a pv stream, from a certain frequency upwards, up or down a fixed amount (in Hz). It can be used to transform a harmonic spectrum into an inharmonic one. The *kkeepform* flag can be used to try and preserve formants for possibly interesting and unusual spectral modifications.

### Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

### Example 698. Example

```
asig  in                               ; get the signal in
fsig  pvsanal  asig, 1024, 256, 1024, 1 ; analyse it
ftps  pvshift   fsig, 100, 0           ; add 100 Hz to each component
atps  pvsynth  ftps                  ; synthesise it
```

Depending on the input, this will transform a pitched sound into an inharmonic, bell-like sound.

Here is an example of the use of the *pvshift* opcode. It uses the file *pvshift.csd* [examples/pvshift.csd].

### Example 699. Example of the *pvshift* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pvsifd

pvsifd — Instantaneous Frequency Distribution, magnitude and phase analysis.

## Description

The pvsifd opcode takes an input a-rate signal and performs an Instantaneous Frequency, magnitude and phase analysis, using the STFT and pvsifd (Instantaneous Frequency Distribution), as described in Lazarini et al, "Time-stretching using the Instantaneous Frequency Distribution and Partial Tracking", Proc.of ICMC05, Barcelona. It generates two PV streaming signals, one containing the amplitudes and frequencies (a similar output to pvsanal) and another containing amplitudes and unwrapped phases.

## Syntax

```
ffr,fphs pvsifd ain, ifftsize, ihopsize, iwintype[,iscal]
```

## Performance

*ffr* -- output pv stream in AMP\_FREQ format

*fphs* -- output pv stream in AMP\_PHASE format

*ifftsize* -- FFT analysis size, must be power-of-two and integer multiple of the hopsize.

*ihopsize* -- hopsize in samples

*iwintype* -- window type (0: Hamming, 1: Hanning)

*iscal* -- amplitude scaling (defaults to 1).

### Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

Here is an example of the pvsifd opcode. It uses the file *pvsifd.csd* [examples/pvsifd.csd].

### Example 700. Example of the pvsifd opcode.

# pvsinfo

pvsinfo — Get information from a PVOC-EX formatted source.

## Description

Get format information about fsrc, whether created by an opcode such as pvsanal, or obtained from a PVOCEX file by pvsread. This information is available at init time, and can be used to set parameters for other pvs opcodes, and in particular for creating function tables (e.g. for pvsftw), or setting the number of oscillators for pvsadsyn.

## Syntax

```
ioverlap, inumbins, iwinsize, iformat pvsinfo fsrc
```

## Initialization

*ioverlap* -- The stream overlap size.

*inumbins* -- The number of analysis bins (amplitude+frequency) in fsrc. The underlying FFT size is calculated as (*inumbins* -1) \* 2.

*iwinsize* -- The analysis window size. May be larger than the FFT size.

*iformat* -- The analysis frame format. If fsrc is created by an opcode, iformat will always be 0, signifying amplitude+frequency. If fsrc is defined from a PVOC-EX file, iformat may also have the value 1 or 2 (amplitude+phase, complex).

## Examples

Here is an example of the pvsinfo opcode. It uses the file *pvsinfo.csd* [examples/pvsinfo.csd].

### Example 701. Example of the pvsinfo opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>

# pvsinit

pvsinit — Initialise a spectral (f) variable to zero.

## Description

Performs the equivalent to an init operation on an f-variable.

## Syntax

```
fsig pvsinit isize[, iolap, iwinsize, iwintype, iformat]
```

## Performance

*fsig* -- output pv stream set to zero.

*isize* -- size of the DFT frame.

*iolap* -- size of the analysis overlap, defaults to *isize*/4.

*iwinsize* -- size of the analysis window, defaults to *isize*.

*iwintype* -- type of analysis window, defaults to 1, Hanning.

*iformat* -- pvsdata format, defaults to 0:PVS\_AMP\_FREQ.

## Examples

### Example 702. Example

```
fsig pvsinit 1024
```

# pvsin

pvsin — Retrieve an fsig from the input software bus; a pvs equivalent to chani.

## Description

This opcode retrieves an f-sig from the pvs in software bus, which can be used to get data from an external source, using the Csound 5 API. A channel is created if not already existing. The fsig channel is in that case initialised with the given parameters. It is important to note that the pvs input and output (pvsout opcode) busses are independent and data is not shared between them.

## Syntax

```
fsig pvsin kchan[, isize, iolap, iwinsize, iwintype, iformat]
```

## Initialization

*isize* -- initial DFT size, defaults to 1024.

*iolap* -- size of overlap, defaults to *isize*/4.

*iwinsize* -- size of analysis window, defaults to *isize*.

*iwintype* -- type of window, defaults to Hanning (1) (see *pvsanal*)

*iformat* -- data format, defaults 0 (PVS\_AMP\_FREQ). Other possible values are 1 (PVS\_AMP\_PHASE), 2 (PVS\_COMPLEX) or 3 (PVS\_TRACKS).

## Performance

*fsig* -- output fsig.

*kchan* -- channel number. If non-existent, a channel will be created.

## Examples

### Example 703. Example

```
fsig pvsin 0 ; get data from pvs in bus channel 0
```

# pvslock

pvslock — Frequency lock an input fsig

## Description

This opcode searches for spectral peaks and then locks the frequencies around those peaks. This is similar to phase-locking in non-streaming PV processing. It can be used to improve timestretching and pitch-shifting quality in PV processing.

## Syntax

```
fsig pvslock fsigin, klock
```

## Performance

*fsig* -- output pv stream

*fsigin* -- input pv stream.

*klock* -- frequency lock, 1 -> lock, 0 -> unlock (bypass).

### Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

Here is an example of the pvslock opcode. It uses the file *pvslock.csd* [examples/pvslock.csd].

### Example 704. Example of the pvslock opcode.

# pvsmaska

pvsmaska — Modify amplitudes using a function table, with dynamic scaling.

## Description

Modify amplitudes of fsrc using function table, with dynamic scaling.

## Syntax

```
fsig pvsmaska fsrc, ifn, kdepth
```

## Initialization

*ifn* -- The f-table to use. Given fsrc has N analysis bins, table ifn must be of size N or larger. The table need not be normalized, but values should lie within the range 0 to 1. It can be supplied from the score in the usual way, or from within the orchestra by using *pvsinfo* to find the size of fsrc, (returned by *pvsinfo* in inbins), which can then be passed to ftgen to create the f-table.

## Performance

*kdepth* -- Controls the degree of modification applied to fsrc, using simple linear scaling. 0 leaves amplitudes unchanged, 1 applies the full profile of ifn.

Note that power-of-two FFT sizes are particularly convenient when using table-based processing, as the number of analysis bins (inbins) is then a power-of-two plus one, for which an exactly matching f-table can be created. In this case it is important that the f-table be created with a size of inbins, rather than as a power of two, as the latter will copy the first table value to the guard point, which is inappropriate for this opcode.

### Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

Here is an example of the use of the *pvsmaska* opcode. It uses the file *pvsmaska.csd* [examples/pvsmaska.csd].

### Example 705. Example of the *pvsmaska* opcode.

# pvsmorph

pvsmorph — Performs morphing (or interpolation) between two source fsigs.

## Description

Performs morphing (or interpolation) between two source fsigs.

## Syntax

```
fsig pvsmorph fsig1, fsig2, kampint, kfrqint
```

## Performance

The operation of this opcode is similar to that of *pvinterp* (q.v.), except in using *fsigs* rather than analysis files, and the absence of spectral envelope preservation. The amplitudes and frequencies of *fsig1* are interpolated with those of *fsig2*, depending on the values of *kampint* and *kfrqint*, respectively. These range between 0 and 1, where 0 means *fsig1* and 1, *fsig2*. Anything in between will interpolate amps and/or freqs of the two fsigs.

With this opcode, morphing can be performed on real-time audio input, by using *pvsanal* to generate *fsig1* and *fsig2*. These must have the same format.

### Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

Here is an example of the *pvsmorph* opcode. It uses the file *pvsmorph.csd* [examples/pvsmorph.csd].

### Example 707. Example of the *pvsmorph* opcode.

# pvsSmooth

**pvsSmooth** — Smooth the amplitude and frequency time functions of a pv stream using parallel 1st order lowpass IIR filters with time-varying cutoff frequency.

## Description

Smooth the amplitude and frequency time functions of a pv stream using a 1st order lowpass IIR with time-varying cutoff frequency. This opcode uses the same filter as the *tone* opcode, but this time acting separately on the amplitude and frequency time functions that make up a pv stream. The cutoff frequency parameter runs at the control-rate, but unlike *tone* and *tonek*, it is not specified in Hz, but as fractions of 1/2 frame-rate (actually the pv stream sampling rate), which is easier to understand. This means that the highest cutoff frequency is 1 and the lowest 0; the lower the frequency the smoother the functions and more pronounced the effect will be.

These are filters applied to control signals so the effect is basically blurring the spectral evolution. The effects produced are more or less similar to *pvsblur*, but with two important differences: 1.smoothing of amplitudes and frequencies use separate sets of filters; and 2. there is no increase in computational cost when higher amounts of 'blurring' (smoothing) are desired.

## Syntax

```
fsig pvsSmooth fsigin, kacf, kfef
```

## Performance

*fsig* -- output pv stream

*fsigin* -- input pv stream.

*kacf* -- amount of cutoff frequency for amplitude function filtering, between 0 and 1, in fractions of 1/2 frame-rate.

*kfef* -- amount of cutoff frequency for frequency function filtering, between 0 and 1, in fractions of 1/2 frame-rate.

### Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

Here is an example of the *pvsSmooth* opcode. It uses the file *pvsSmooth.csd* [examples/pvsSmooth.csd].

### Example 709. Example of the *pvsSmooth* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

</CsScore>
</CsoundSynthesizer>
```

The formula for calculating the cutoff frequency of the filter: frame rate / hopsize = new frame starts per second (in Hz), then the percentage of half the framerate. For example, looking at the first note in the example, the frame rate is  $44100 / 256 = 172,265625$  Hz (= 172 new frame starts per second). half of the frame rate is about 86 Hz, and one percent of this is 0.86 Hz.

# pvsout

pvsout — Write a fsig to the pvs output bus.

## Description

This opcode writes a fsig to a channel of the pvs output bus. Note that the pvs out bus and the pvs in bus are separate and independent. A new channel is created if non-existent.

## Syntax

```
pvsout fsig, kchan
```

## Performance

*fsig* -- fsig input data.

*kchan* -- pvs out bus channel number.

## Examples

### Example 710. Example

```
asig      in
fsig      pvsanal asig, 1024, 256, 1024, 1 ; input
                                                ; analysis
pvsout   fsig, 0                                ; write signal to pvs out bus channel 0
```

# pvsosc

pvsosc — PVS-based oscillator simulator.

## Description

Generates periodic signal spectra in AMP-FREQ format, with the option of four wave types:

1. sawtooth-like (harmonic weight  $1/n$ , where  $n$  is partial number)
2. square-like (similar to 1., but only odd partials)
3. pulse (all harmonics with same weight)
4. cosine

Complex waveforms (ie. all types except cosine) contain all harmonics up to the Nyquist. This makes pvsosc an option for generation of band-limited periodic waves. In addition, types can be changed using a k-rate variable.

## Syntax

```
fsig pvsosc kamp, kfreq, ktype, isize [,ioverlap] [, iwinsize] [, iwinstype] [, iformat]
```

## Initialisation

*fsig* -- output pv stream set to zero.

*isize* -- size of analysis frame and window.

*ioverlap* -- (Optional) size of overlap, defaults to *isize*/4.

*iwinsize* -- (Optional) window size, defaults to *isize*.

*iwinstype* -- (Optional) window type, defaults to Hanning. The choices are currently:

- 0 = Hamming window
- 1 = von Hann window

*iformat* -- (Optional) data format, defaults to 0 which produces AMP:FREQ data. That is currently the only option.

## Performance

*kamp* -- signal amplitude. Note that the actual signal amplitude can, depending on wave type and frequency, vary slightly above or below this value. Generally the amplitude will tend to exceed *kamp* on higher frequencies ( $> 1000$  Hz) and be reduced on lower ones. Also due to the overlap-add process, when resynthesizing with pvsynth, frequency glides will cause the output amplitude to fluctuate above and below *kamp*.

*kfreq* -- fundamental frequency in Hz.

*ktype* -- wave type: 1. sawtooh-like, 2.square-like, 3.pulse and any other value for cosine.

## Examples

Here is an example of the pvsosc opcode. It uses the file *pvsosc.csd* [examples/pvsosc.csd].

### Example 711. Example of the pvsosc opcode

# **pvspitch**

**pvspitch** — Track the pitch and amplitude of a PVS signal.

## **Description**

Track the pitch and amplitude of a PVS signal as k-rate variables.

## **Syntax**

```
kfr, kamp pvspitch fsig, kthresh
```

## **Performance**

*kamp* -- Amplitude of fundamental frequency

*kfr* -- Fundamental frequency

*fsig* -- an input pv stream

*kthresh* -- analysis threshold (between 0 and 1). Higher values will eliminate low-amplitude components from the analysis.

## **Performance**

The pitch detection algorithm implemented by *pvspitch* is based upon J. F. Schouten's hypothesis of the neural processes of the brain used to determine the pitch of a sound after the frequency analysis of the basilar membrane. Except for some further considerations, *pvspitch* essentially seeks out the highest common factor of an incoming sound's spectral peaks to find the pitch that may be attributed to it.

In general, input sounds that exhibit pitch will also exhibit peaks in their spectrum according to where their harmonics lie. There are some exceptions, however. Some sounds whose spectral representation is continuous can impart a sensation of pitch. Such sounds are explained by the centroid or center of gravity of the spectrum and are beyond the scope of the method of pitch detection implemented by *pvspitch* (Using opcodes like *pvscent* might be more appropriate in these cases).

*pvspitch* is able (using a previous analysis *fsig* generated by *pvsanal*) to locate the spectral peaks of a signal. The threshold parameter (*kthresh*) is of utmost importance, as adjusting it can introduce weak yet significant harmonics into the calculation of the fundamental. However, bringing *kthresh* too low would allow harmonically unrelated partials into the analysis algorithm and this will compromise the method's accuracy. These initial steps emulate the response of the basilar membrane by identifying physical characteristics of the input sound. The choice of *kthresh* depends on the actual level of the input signal, since its range (from 0 to 1) spans the whole dynamic range of an analysis bin (from -inf to 0dBFS).

It is important to remember that the input to the *pvspitch* opcode is assumed to be characterised by strong partials within its spectrum. If this is not the case, the results outputted by the opcode may not bear any relation to the pitch of the input signal. If a spectral frame with many unrelated partials was analysed, the greatest common factor of these frequency values that allows for adjacent "harmonics" would be chosen. Thus, noisy frames can be characterised by low frequency outputs of *pvspitch*. This fact allows for a primitive type of instrumental transient detection, as the attack portion of some instrumental tones contain inharmonic components. Should the lowest frequency of the analysed melody be known, then all frequencies detected below this threshold are inaccurate readings, due to the presence of unrelated partials.

In order to facilitate efficient testing of the *pvspeech* algorithm, an amplitude value proportional to the one in the observed in the signal frame is also outputted (*kamp*). The results of *pvspeech* can then be employed to drive an oscillator whose pitch can be audibly compared with that of the original signal (In the example below, an oscillator generates a signal which appears a fifth above the detected pitch).

## Examples

Here is an example of the *pvspeech* opcode. It uses the file *pvspeech.csd* [examples/pvspeech.csd]. This example uses realtime audio input but can be used for audiofile input as well.

# **pvstanal**

**pvstanal** — Phase vocoder analysis processing with onset detection/processing.

## **Description**

*pvstanal* implements phase vocoder analysis by reading function tables containing sampled-sound sources, with *GEN01*, and *pvstanal* will accept deferred allocation tables.

This opcode allows for time and frequency-independent scaling. Time is advanced internally, but controlled by a tempo scaling parameter; when an onset is detected, timescaling is momentarily stopped to avoid smearing of attacks. The quality of the effect is generally improved with phase locking switched on.

*pvstanal* will also scale pitch, independently of frequency, using a transposition factor (k-rate).

## **Syntax**

```
fsig pvstanal ktimescal, kamp, kpitch, ktab, [kdetect, kwrap, ioffset, ifftsize, ihop, idbthresh]
```

## **Initialization**

*ifftsize* -- FFT size (power-of-two), defaults to 2048.

*ihop* -- hopsize, defaults to 512

*ioffset* -- startup read offset into table, in secs.

*idbthresh* -- threshold for onset detection, based on dB power spectrum ratio between two successive windows. A detected ratio above it will cancel timescaling momentarily, to avoid smearing (defaults to 1). By default anything more than a 1 dB inter-frame power difference will be detected as an onset.

## **Performance**

*ktimescal* -- timescaling ratio, < 1 stretch, > 1 contract.

*kamp* -- amplitude scaling

*kpitch* -- grain pitch scaling (1=normal pitch, < 1 lower, > 1 higher; negative, backwards)

*kdetect* -- 0 or 1, to switch onset detection/processing. The onset detector checks for power difference between analysis windows. If more than what has been specified in the dbthresh parameter, an onset is declared. It suspends timescaling momentarily so the onsets are not modified.

*ktab* -- source signal function table. Deferred-allocation tables (see *GEN01*) are accepted, but the opcode expects a mono source. Tables can be switched at k-rate.

*kwrap* -- 0 or 1, to switch on/off table wrap-around read (default to 1)

## **Examples**

Here is an example of the *pvstanal* opcode. It uses the file *pvstanal.csd* [examples/pvstanal.csd].

**Example 713. Example of the pvstanal opcode.**

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pvstencil

**pvstencil** — Transforms a pvoc stream according to a masking function table.

## Description

Transforms a pvoc stream according to a masking function table; if the pvoc stream amplitude falls below the value of the function for a specific pvoc channel, it applies a gain to that channel.

The pvoc stream amplitudes are compared to a masking table, if the fall below the table values, they are scaled by *kgain*. Prior to the operation, table values are scaled by *klevel*, which can be used as masking depth control.

Tables have to be at least fftsize/2 in size; for most GENS it is important to use an extended-guard point (size power-of-two plus one), however this is not necessary with GEN43.

One of the typical uses of *pvstencil* would be in noise reduction. A noise print can be analysed with *pvalan* into a PVOC-EX file and loaded in a table with *GEN43*. This then can be used as the masking table for *pvstencil* and the amount of reduction would be controlled by *kgain*. Skipping post-normalisation will keep the original noise print average amplitudes. This would provide a good starting point for a successful noise reduction (so that *klevel* can be generally set to close to 1).

Other possible transformation effects are possible, such as filtering and `inverse-masking'.

## Syntax

```
fsig pvstencil fsigin, kgain, klevel, iftable
```

## Performance

*fsig* -- output pv stream

*fsigin* -- input pv stream.

*kgain* -- `stencil' gain.

*klevel* -- masking function level (scales the ftable prior to `stenciling') .

*iftable* -- masking function table.

### Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

### Example 714. Example

```
fsig    pvsanal   asig, 1024, 256, 1024, 1
fclean pvcstencil fsig, 0, 1, 1

# pvs voc

pvs voc — Combine the spectral envelope of one fsig with the excitation (frequencies) of another.

## Description

This opcode provides support for cross-synthesis of amplitudes and frequencies. It takes the amplitudes of one input fsig and combines with frequencies from another. It is a spectral version of the well-known channel vocoder.

## Syntax

```
fsig pvs voc famp, fexc, kdepth, kgain [,kcoefs]
```

## Performance

*fsig* -- output pv stream

*famp* -- input pv stream from which the amplitudes will be extracted

*fexc* -- input pv stream from which the frequencies will be taken

*kdepth* -- depth of effect, affecting how much of the frequencies will be taken from the second fsig: 0, the output is the famp signal, 1 the output is the famp amplitudes and fexc frequencies.

*kgain* -- gain boost/attenuation applied to the output.

*kcoefs* -- number of cepstrum coefs used in spectral envelope estimation (defaults to 80).

### Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

Here is an example of the pvs voc opcode. It uses the file *pvs voc.csd* [examples/pvs voc.csd].

### Example 715. Example of the pvs voc opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# pvs warp

pvs warp — Warp the spectral envelope of a PVS signal

## Description

Warp the spectral envelope of a PVS signal by means of shifting and scaling.

## Syntax

```
fsig pvs warp fsigin, kscal, kshift[, klowest, kmeth, kgain, kcoefs]
```

## Performance

*fsig* -- output pv stream

*fsigin* -- input pv stream

*kscal* -- spectral envelope scaling ratio. Values > 1 stretch the envelope and < 1 compress it.

*kshift* -- spectral envelope shift, values > 0 shift the envelope linearly upwards and values < 1 shift it downwards.

*klowest* -- lowest frequency shifted (affects only kshift, defaults to 0).

*kmethod* -- spectral envelope extraction method 1: liftered cepstrum method; 2: true envelope method (defaults to 1).

*kgain* -- amplitude scaling (defaults to 1).

*kcoefs* -- number of cepstrum coefs used in formant preservation (defaults to 80).

## Warning

It is unsafe to use the same f-variable for both input and output of pvs opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

Here is an example of the pvs warp opcode. It uses the file *pvs warp.csd* [examples/pvs warp.csd].

### Example 718. Example of the pvs warp opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

</CsoundSynthesizer>
```

Used with vocal sounds, it will shift the formants and result in a changed vowel timbre, similar to the effect of a singer inhaling helium (the 'donald duck' effect).

# pvs2tab

pvs2tab — Copies spectral data to k-rate arrays (or t-variables). Also known as pvs2array.

## Description

Copies a pvs frame to a t-variable. Currently only AMP+FREQ and AMP+PHASE formats allowed. Since t-vars are an earlier version of k-rate arrays, the opcode also works with these. The opcode pvs2array is an alias of this one.

## Syntax

```
kframe pvs2tab tvar|kvar[], fsig
```

## Performance

*kframe* -- current copied frame number. It can be used to detect when a new frame has been copied.

*tvar/kvar[]* -- t-variable or k-rate array containing the output. It is produced at every k-period, but may not contain a new frame, pvs frames are produced at their own frame rate that is independent of kr. Generally, this vector needs to be big enough to contain the frame samples, i.e. N+2 (N is the dft size). If smaller, only a portion of the frame will be copied; if bigger, unused points will exist at higher indexes.

*fsig* -- input fsig to be copied.

## Examples

### Example 719. Example

```
karr[] init 1026
al inch 1
fsigl  pvsanal al, 1024,256,1024, 1
kframe pvs2tabkarr, fsigl
```

# pyassign Opcodes

**pyassign** — Assign the value of the given Csound variable to a Python variable possibly destroying its previous content.

## Syntax

```
pyassign "variable", kvalue  
  
pyassigni "variable", ivalue  
  
pylassign "variable", kvalue  
  
pylassigni "variable", ivalue  
  
pyassignt ktrigger, "variable", kvalue  
  
pylassignt ktrigger, "variable", kvalue
```

## Description

Assign the value of the given Csound variable to a Python variable possibly destroying its previous content. The resulting Python object will be a float.

pylcallni "callable", nresults, iresult1, ..., iresultn, iarg1, ...
```

## Description

This family of opcodes call the specified Python callable at k-time and i-time (i suffix), passing the given arguments. The call is performed in the global environment and the result (the returning value) is copied into the Csound output variables specified.

They pass any number of parameters which are cast to float inside the Python interpreter.

The *pycall/pycalli*, *pycall1/pycall1i* ... *pycall8/pycall8i* opcodes can accommodate for a number of results ranging from 0 to 8 according to their numerical prefix (0 is omitted).

The *pycalln/pycallni* opcodes can accommodate for any number of results: the callable name is followed by the number of output arguments, then come the list of Csound output variable and the list of parameters to be passed.

The returning value of the callable must be `None` for *pycall* or *pycalli*, a float for *pycall1i* or *pycall1i* and a tuple (with proper size) of floats for the *pycall2/pycall2i* ... *pycall8/pycall8i* and *pycalln/pycallni* opcodes.

## Examples

### Example 720. Calling a C or Python function

Supposing we have previously defined or imported a function named `get_number_from_pool` as:

```
from random import random, choice

# a pool of 100 numbers
pool = [i ** 1.3 for i in range(100)]

def get_number_from_pool(n, p):
    # substitute an old number with the new number?
    if random() < p:
        i = choice(range(len(pool)))
        pool[i] = n

    # return a random number from the pool
    return choice(pool)
```

then the following orchestra code

```
k2  pycall1 "get_number_from_pool", k1, p6
```

would set *k2* randomly from a pool of numbers changing in time. You can pass new pools elements and control the change rate from the orchestra.

### Example 721. Calling a Function Object

A more generic implementation of the previous example makes use of a simple function object:

```
from random import random, choice

class GetNumberFromPool:
    def __init__(self, e, begin=0, end=100, step=1):
        self.pool = [i ** e for i in range(begin, end, step)]
    def __call__(self, n, p):
        # substitute an old number with the new number?
        if random() < p:
            i = choice(range(len(pool)))
            pool[i] = n
        # return a random number from the pool
        return choice(pool)

get_number_from_pool1 = GetNumberFromPool(1.3)
get_number_from_pool2 = GetNumberFromPool(1.5, 50, 250, 2)
```

Then the following orchestra code:

```
k2  pycall1 "get_number_from_pool1", k1, p6
k4  pycall1 "get_number_from_pool2", k3, p7
```

would set *k2* and *k4* randomly from a pool of numbers changing in time. You can pass new pools elements (here *k1* and *k3*) and control the change rate (here *p6* and *p7*) from the orchestra.

As you can see in the first snippet, you can customize the initialization of the pool as well as create several pools.

## Credits

# pyeval Opcodes

pyeval — Evaluate a generic Python expression and store the result in a Csound variable at k-time or i-time (i suffix).

## Syntax

```
kresult pyeval "expression"

iresult pyevali "expression"

kresult pyleval "expression"

iresult pylevali "expression"

kresult pyevalt ktrigger, "expression"

kresult pyevalti ktrigger, "expression"
```

## Description

These opcodes evaluate a generic Python expression and store the result in a Csound variable at k-time or i-time (i suffix).

The expression must evaluate in a float or an object that can be cast to a float.

They can be used effectively to transfer data from a Python object into a Csound variable.

## Example of the pyeval Opcode Group

The code:

```
k1      pyeval      "v1 "
```

will copy the content of the Python variable *v1* into the Csound variable *k1* at each k-time.

## Credits

Copyright (c) 2002 by Maurizio Umberto Puxeddu. All rights reserved. Portions copyright (c) 2004 and 2005 by Michael Gogins. This document has been updated Sunday 25 July 2004 and 1 February 2005 by Michael Gogins.

# pyexec Opcodes

`pyexec` — Execute a script from a file at k-time or i-time (i suffix).

## Syntax

```
pyexec "filename"

pyexeci "filename"

pylexec "filename"

pylexeci "filename"

pyexec ktrigger, "filename"

plyexec ktrigger, "filename"
```

## Description

Execute a script from a file at k-time or i-time (i suffix).

This is not the same as calling the script with the `system()` call, since the code is executed by the embedded interpreter.

The code contained in the specified file is executed in the global environment for opcodes `pyexec` and `pyexeci` and in the private environment for the opcodes `pylexec` and `pylexeci`.

These opcodes perform no message passing. However, since the statement has access to the main namespace and the private namespace, it can interact with objects previously created in that environment.

The "local" version of the `pyexec` opcodes are useful when the code ran by different instances of an instrument should not interact.

## Example of the pyexec Opcode Group

### Example 722. Orchestra (pyexec.orc)

```
sr=44100
kr=4410
ksmps=10
nchnls=1

;If you're not running CsoundAC you need the following line
;to initialize the python interpreter
;pyinit

        pyruni "import random"
        pyexeci "pyexec1.py"

instr 1
```

```
    pyexec      "pyexec2.py"
    pyllexci    "pyexec3.py"
    pyllexec    "pyexec4.py"

endin
```

### Example 723. Score (pyexec.sco)

```
i1 0 0.01
i1 0 0.01
```

### Example 724. The pyexec1.py Script

```
import time, os
print
print "Welcome to Csound!"

try:
    s = ' , %s?' % os.getenv('USER')
except:
    s = '?'

print 'What sound do you want to hear today%s' % s
answer = raw_input()
```

### Example 725. The pyexec2.py script

```
print 'your answer is "%s"' % answer
```

### Example 726. The pyexec3.py script

```
message = 'a private random number: %f' % random.random()
```

### Example 727. The pyexec4.py script

```
print message
```

If I run this example on my machine I get something like:

```
Using ../../csound.xmg
Csound Version 4.19 (Mar 23 2002)
Embedded Python interpreter version 2.2
```

```
orchname: pyexec.orc
scorename: pyexec.sco
sorting score ...
    ... done
orch compiler:
11 lines read
    instr 1
Csound Version 4.19 (Mar 23 2002)
displays suppressed

Welcome to Csound!
What sound do you want to hear today, maurizio?
```

then I answer

```
a sound
```

then Csound continues with the normal performance

```
your answer is "a sound"
a private random number: 0.884006
new alloc for instr 1:
your answer is "a sound"
a private random number: 0.884006
your answer is "a sound"
a private random number: 0.889868
your answer is "a sound"
a private random number: 0.884006
your answer is "a sound"
a private random number: 0.889868
your answer is "a sound"
a private random number: 0.884006
your answer is "a sound"
...
...
```

In the same instrument a message is created in the private namespace and printed, appearing different for each instance.

# pyinit Opcodes

`pyinit` — Initialize the Python interpreter.

## Syntax

```
pyinit
```

## Description

In Csound, you must first invoke the *pyinit* opcode in the orchestra header to initialize the Python interpreter, before using any of the other Python opcodes.

But if you use the Python opcodes within CsoundAC, or from a python frontend using the csnd6 module, Csound, you need not invoke *pyinit*, because the Python interpreter will have already been initialized. In this case, CsoundAC (or the csnd6 python module) automatically creates a Python interface to the Csound API. In CsoundAC, this exists in the form a global instance of the `CsoundAC.CppSound` class named `csound`. From a python frontend which imports the csnd6 module, the name of the variable holding the Csound instance will depend on the frontend code. Therefore, Python code written in the Csound orchestra has access to the global `csound` object.

The running Csound instance in which *pyinit* has been called is stored in a global python variable called `_CSOUND_`. This holds the actual memory address of the instance and it can be used with the csnd6 module via the `csoundGetInstance(instance)` call. This python function returns an object that can be used with all the Csound API functions.

# pyrun Opcodes

`pyrun` — Run a Python statement or block of statements.

## Syntax

```
pyrun "statement"

pyruni "statement"

pylrun "statement"

pylruni "statement"

pyrunt ktrigger, "statement"

pylrunt ktrigger, "statement"
```

## Description

Execute the specified Python statement at k-time (`pyrun` and `pylrun`) or i-time (`pyruni` and `pylruni`).

The statement is executed in the global environment for `pyrun` and `pyruni` or the local environment for `pylrun` and `pylruni`.

These opcodes perform no message passing. However, since the statement have access to the main namespace and the private namespace, it can interact with objects previously created in that environment.

The "local" version of the `pyrun` opcodes are useful when the code ran by different instances of an instrument should not interact.

## Example of the pyrun Opcode Group

### Example 728. Orchestra

```
sr=44100
kr=4410
ksmps=10
nchnls=1

;If you're not running CsoundAC you need the following line
;to initialize the python interpreter
;pyinit

pyruni "import random"

instr 1
    ; This message is stored in the main namespace
    ; and is the same for every instance
    pyruni "message = 'a global random number: %f' % random.random()"
    pyrun   "print message"

    ; This message is stored in the private namespace
    ; and is different for different instances
```

```
pylruni "message = 'a private random number: %f' % random.random()"
pylrun  "print message"
endin
```

### Example 729. Score

```
i1 0 0.1
```

Running this score you should get intermixed pairs of messages from the two instances of instrument 1.

The first message of each pair is stored into the main namespace and so the second instance overwrites the message of the first instance. The result is that first message will be the same for both instances.

The second message is different for the two instances, being stored in the private namespace.

# pwd

pwd — Asks the underlying operating system for the current directory name as a string.

## Description

**pwd** call the operating system to determine the current directory (folder). **pwd** runs at i-time only.

## Syntax

*Sres* **pwd**

## Performance

*Sres* -- the returned string.

## Example

Here is an example of the pwd opcode. It uses the file *pwd.csd* [examples/pwd.csd].

### Example 730. Example of the **pwd** opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out   Audio in
-odac          ; -iadc    ;;;RT audio I/O
; For Non-realtime output leave only the line below:
; -o system.wav -W ;; for file output any platform
</CsOptions>
<CsInstruments>

; Initialize the global variables.
sr = 44100
kr = 4410
ksmps = 10
nchnls = 1

instr 1
; Waits for command to execute before continuing
Swd pwd
puts Swd, 1

# qinf

qinf — Questions whether the argument is a infinite number

## Description

Returns the number of times the argument is not a number, with the sign of the first infinity.

## Syntax

```
qinf(x) (no rate restriction)
```

## Examples

Here is an example of the qinf opcode. It uses the file *qinf.csd* [examples/qinf.csd].

### Example 731. Example of the qinf opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# r2c

r2c — Real to complex format conversion.

## Description

Converts a real-valued input array in real-imaginary interleaved complex format, setting its imaginary parts to 0. The output array will be double the size of the input. This is a utility operation to facilitate complex-value operations on real arrays.

## Syntax

```
kout[] r2c kin[]
```

## Performance

*kout[]* -- output array containing the complex-valued real-imaginary output. It will be created if it does not exist.

*kin[]* -- input array containing the real-valued input.

## Examples

Here is an example of the r2c opcode. It uses the file *r2c.csd* [examplesr2c.csd].

### Example 733. Example of the r2c opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# rand

rand — Generates a controlled random number series.

## Description

Output is a controlled random number series between  $-amp$  and  $+amp$

## Syntax

```
ares rand xamp [, iseed] [, isel] [, ioffset]
```

```
kres rand xamp [, iseed] [, isel] [, ioffset]
```

## Initialization

*iseed* (optional, default=0.5) -- a seed value for the recursive pseudo-random formula. A value between 0 and 1 will produce an initial output of  $kamp * iseed$ . A value greater than 1 will be seeded from the system clock. A negative value will cause seed re-initialization to be skipped. The default seed value is .5.

*isel* (optional, default=0) -- if zero, a 16-bit number is generated. If non-zero, a 31-bit random number is generated. Default is 0.

*ioffset* (optional, default=0) -- a base value added to the random result. New in Csound version 4.03.

## Performance

*kamp*, *xamp* -- range over which random numbers are distributed.

*ares*, *kres* -- Random number produced.

The internal pseudo-random formula produces values which are uniformly distributed over the range *kamp* to  $-kamp$ . *rand* will thus generate uniform white noise with an R.M.S value of  $kamp / \sqrt{2}$ .

The value *ares* or *kres* is within a half-closed interval which contains  $-xamp$ , but never contains  $+xamp$ .

## Examples

Here is an example of the rand opcode. It uses the file *rand.csd* [examples/rand.csd].

### Example 734. Example of the rand opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## See Also

*randh, randi*

## Credits

Thanks to a note from John ffitch, I changed the names of the parameters.

# randh

randh — Generates random numbers and holds them for a period of time.

## Description

Generates random numbers and holds them for a period of time.

## Syntax

```
ares randh xamp, xcps [, iseed] [, isize] [, ioffset]
```

```
kres randh kamp, kcps [, iseed] [, isize] [, ioffset]
```

## Initialization

*iseed* (optional, default=0.5) -- seed value for the recursive pseudo-random formula. A value between 0 and +1 will produce an initial output of *kamp* \* *iseed*. A negative value will cause seed re-initialization to be skipped. A value greater than 1 will seed from system time, this is the best option to generate a different random sequence for each run.

*isize* (optional, default=0) -- if zero, a 16 bit number is generated. If non-zero, a 31-bit random number is generated. Default is 0.

*ioffset* (optional, default=0) -- a base value added to the random result. New in Csound version 4.03.

## Performance

*kamp*, *xamp* -- range over which random numbers are distributed.

*kcps*, *xcps* -- the frequency which new random numbers are generated.

The internal pseudo-random formula produces values which are uniformly distributed over the range -*kamp* to +*kamp*. *rand* will thus generate uniform white noise with an R.M.S value of *kamp* /  $\sqrt{2}$ .

The remaining units produce band-limited noise: the *kcps* and *xcps* parameters permit the user to specify that new random numbers are to be generated at a rate less than the sampling or control frequencies. *randh* will hold each new number for the period of the specified cycle.

## Examples

Here is an example of the randh opcode. It uses the file *randh.csd* [examples/randh.csd].

### Example 735. Example of the randh opcode.

*rand, randi*

# randi

rand — Generates a controlled random number series with interpolation between each new number.

## Description

Generates a controlled random number series with interpolation between each new number.

## Syntax

```
ares randi xamp, xcps [, iseed] [, isize] [, ioffset]
```

```
kres randi kamp, kcps [, iseed] [, isize] [, ioffset]
```

## Initialization

*iseed* (optional, default=0.5) -- seed value for the recursive pseudo-random formula. A value between 0 and +1 will produce an initial output of *kamp* \* *iseed*. A negative value will cause seed re-initialization to be skipped. A value greater than 1 will seed from system time, this is the best option to generate a different random sequence for each run.

*isize* (optional, default=0) -- if zero, a 16 bit number is generated. If non-zero, a 31-bit random number is generated. Default is 0.

*ioffset* (optional, default=0) -- a base value added to the random result. New in Csound version 4.03.

## Performance

*kamp*, *xamp* -- range over which random numbers are distributed.

*kcps*, *xcps* -- the frequency which new random numbers are generated.

The internal pseudo-random formula produces values which are uniformly distributed over the range *kamp* to -*kamp*. *rand* will thus generate uniform white noise with an R.M.S value of *kamp* /  $\sqrt{2}$ .

The remaining units produce band-limited noise: the *kcps* and *xcps* parameters permit the user to specify that new random numbers are to be generated at a rate less than the sampling or control frequencies. *randi* will produce straight-line interpolation between each new number and the next.

## Examples

Here is an example of the randi opcode. It uses the file *randi.csd* [examples/randi.csd].

# randomh

randomh — Generates random numbers with a user-defined limit and holds them for a period of time.

## Description

Generates random numbers with a user-defined limit and holds them for a period of time.

## Syntax

```
ares randomh kmin, kmax, xcps [,imode] [,ifirstval]
```

```
kres randomh kmin, kmax, kcps [,imode] [,ifirstval]
```

## Initialization

*imode* (optional, default=0) -- generation mode of the first output value (see below)

*ifirstval* (optional, default=0) -- first output value

## Performance

*kmin* -- minimum range limit

*kmax* -- maximum range limit

*kcps*, *xcps* -- rate of random break-point generation

The *randomh* opcode is similar to *randh* but allows the user to set arbitrary minimum and maximum values.

When *imode* = 0 (the default), the *kmin* argument value is outputted during  $1/kcps$  (resp.  $1/xcps$ ) seconds at the beginning of the note. Then, the normal process takes place with a new random number generated and held every  $1/kcps$  (resp.  $1/xcps$ ) seconds.

When *imode* = 2, the *ifirstval* argument value is outputted during  $1/kcps$  (resp.  $1/xcps$ ) seconds at the beginning of the note. Then, the normal process takes place with a new random number generated and held every  $1/kcps$  (resp.  $1/xcps$ ) seconds.

When *imode* = 3, the generation process begins with a random value from the initialization time.

## Examples

Here is an example of the *randomh* opcode. It uses the file *randomh.csd* [examples/randomh.csd].

### Example 738. Example of the randomh opcode.

*randh, random, randomi*

## Credits

Author: Gabriel Maldonado

Arguments *imode* and *ifirstval* added by François Pinot, Jan. 2011, after a discussion with Peiman Khosravi on the csnd list.

Example written by Kevin Conder, adapted for new args by François Pinot.

# randomi

randomi — Generates a user-controlled random number series with interpolation between each new number.

## Description

Generates a user-controlled random number series with interpolation between each new number.

## Syntax

```
ares randomi kmin, kmax, xcps [,imode] [,ifirstval]
```

```
kres randomi kmin, kmax, kcps [,imode] [,ifirstval]
```

## Initialization

*imode* (optional, default=0) -- first interpolation cycle mode (see below)

*ifirstval* (optional, default=0) -- first output value

## Performance

*kmin* -- minimum range limit

*kmax* -- maximum range limit

*kcps*, *xcps* -- rate of random break-point generation

The *randomi* opcode is similar to *randi* but allows the user to set arbitrary minimum and maximum values.

When *imode* = 0 (the default), the *kmin* argument value is outputted during  $1/kcps$  (resp.  $1/xcps$ ) seconds at the beginning of the note, before the first random number is generated. Then the normal interpolation process takes place, first between *kmin* and the first random number generated, and then between successive generated random numbers, each interpolation cycle having a duration of  $1/kcps$  (resp.  $1/xcps$ ) seconds.

When *imode* = 1, a random number is generated at initialization and interpolation begins immediately between the *kmin* argument value and that random number.

When *imode* = 2, a random number is generated at initialization and interpolation begins immediately between the *ifirstval* argument value and that random number.

When *imode* = 3, two random numbers are generated at initialization as breakpoints for the first interpolation cycle.

## Examples

Here is an example of the *randomi* opcode. It uses the file *randomi.csd* [examples/randomi.csd].

**Example 739. Example of the randomi opcode.**

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# rbjeq

rbjeq — Parametric equalizer and filter opcode with 7 filter types, based on algorithm by Robert Bristow-Johnson.

## Description

Parametric equalizer and filter opcode with 7 filter types, based on algorithm by Robert Bristow-Johnson.

## Syntax

```
ar rbjeq asig, kfco, klvl, kQ, ks[, imode]
```

## Initialization

*imode* ( optional, defaults to zero) - sum of:

- 1: skip initialization (should be used in tied, or re-initialized notes only)

and exactly one of the following values to select filter type:

- 0: resonant lowpass filter. kQ controls the resonance: at the cutoff frequency (kfco), the amplitude gain is kQ (e.g. 20 dB for kQ = 10), and higher kQ values result in a narrower resonance peak. If kQ is set to sqrt(0.5) (about 0.7071), there is no resonance, and the filter has a response that is very similar to that of butterlp. If kQ is less than sqrt(0.5), there is no resonance, and the filter has a -6 dB / octave response from about kfco \* kQ to kfco. Above kfco, there is always a -12 dB / octave cutoff.

### NOTE

The rbjeq lowpass filter is basically the same as ar pareq asig, kfco, 0, kQ, 2 but is faster to calculate.

- 2: resonant highpass filter. The parameters are the same as for the lowpass filter, but the equivalent filter is butterhp if kQ is 0.7071, and "ar pareq asig, kfco, 0, kQ, 1" in other cases.
- 4: bandpass filter. kQ controls the bandwidth, which is kfco / kQ, and must be always less than sr / 2. The bandwidth is measured between -3 dB points (i.e. amplitude gain = 0.7071), beyond which there is a +/- 6 dB / octave slope. This filter type is very similar to ar butterbp asig, kfco, kfco / kQ.
- 6: band-reject filter, with the same parameters as the bandpass filter, and a response similar to that of butterbr.
- 8: peaking EQ. It has an amplitude gain of 1 (0 dB) at 0 Hz and sr / 2, and klvl at the center frequency (kfco). Thus, klvl controls the amount of boost (if it is greater than 1), or cut (if it is less than 1). Setting klvl to 1 results in a flat response. Similarly to the bandpass and band-reject filters, the bandwidth is determined by kfco / kQ (which must be less than sr / 2 again); however, this time it is between sqrt(klvl) points (or, in other words, half the boost or cut in decibels). NOTE: excessively low or high values of klvl should be avoided (especially with 32-bit floats), though the opcode was tested with klvl = 0.01 and klvl = 100. klvl = 0 is always an error, unlike in the case of pareq, which does allow a zero level.

- 10: low shelf EQ, controlled by klvl and kS (kQ is ignored by this filter type). There is an amplitude gain of klvl at zero frequency, while the level of high frequencies (around sr / 2) is not changed. At the corner frequency (kfco), the gain is  $\sqrt{klvl}$  (half the boost or cut in decibels). The kS parameter controls the steepness of the slope of the frequency response (see below).
- 12: high shelf EQ. Very similar to the low shelf EQ, but affects the high frequency range.

The default value for imode is zero (lowpass filter, initialization not skipped).

## Performance

*ar* -- the output signal.

*asig* -- the input signal

### NOTE

If the input contains silent sections, on Intel CPUs a significant slowdown can occur due to denormals. In such cases, it is recommended to process the input signal with "denorm" opcode before filtering it with rbjeq (and actually many other filters).

*kfco* -- cutoff, corner, or center frequency, depending on filter type, in Hz. It must be greater than zero, and less than sr / 2 (the range of about sr \* 0.0002 to sr \* 0.49 should be safe).

*klvl* -- level (amount of boost or cut), as amplitude gain (e.g. 1: flat response, 4: 12 dB boost, 0.1: 20 dB cut); zero or negative values are not allowed. It is recognized by the peaking and shelving EQ types (8, 10, 12) only, and is ignored by other filters.

*kQ* -- resonance (also kfco / bandwidth in many filter types). Not used by the shelving EQs (imode = 10 and 12). The exact meaning of this parameter depends on the filter type (see above), but it should be always greater than zero, and usually (*kfco* / *kQ*) less than sr / 2.

*kS* -- shelf slope parameter for shelving filters. Must be greater than zero; a higher value means a steeper slope, with resonance if *kS* > 1 (however, a too high *kS* value may make the filter unstable). If *kS* is set to exactly 1, the shelf slope is as steep as possible without a resonance. Note that the effect of *kS* - especially if it is greater than 1 - also depends on *klvl*, and it does not have any well defined unit.

## Examples

Here is an example of the *rbjeq* opcode. It uses the file *rbjeq.csd* [examples/rbjeq.csd].

### Example 740. An example of the rbjeq opcode.

# readclock

readclock — Reads the value of an internal clock.

## Description

Reads the value of an internal clock.

## Syntax

```
ir readclock inum
```

## Initialization

*inum* -- the number of a clock. There are 32 clocks numbered 0 through 31. All other values are mapped to clock number 32.

*ir* -- value at i-time, of the clock specified by *inum*

## Performance

Between a *clockon* and a *clockoff* opcode, the CPU time used is accumulated in the clock. The precision is machine dependent but is the millisecond range on UNIX and Windows systems. The *readclock* opcode reads the current value of a clock at initialization time.

## Examples

Here is an example of the *readclock* opcode. It uses the file *readclock.csd* [examples/readclock.csd].

### Example 741. Example of the readclock opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# readf

readf — Read a line of text from an external file.

## Description

Read a line of text from an external file once each k-cycle.

## Syntax

```
Sres, kline readf ifilename
```

## Initialization

*filename* -- an integer N denoting a file named "input.N" or a character string (in double quotes, spaces permitted) denoting the external file name. For a string, it may either be a full path name with directory specified or a simple filename. In the later case, the file is sought first in the current directory, then in SSDIR, and finally in SFDIR.

## Performance

*Sres* -- output of the line read from *filename*.

*kline* -- line number, or -1 when end of file has been reached.

This opcode allows a line of text to be read from a named external file. There may be any number of *readf* opcodes in an instrument or orchestra but they read separately from the same or different files.

## Examples

Here is an example of the *readf* opcode. It uses the file *readf.csd* [examples/readf.csd].

### Example 742. Example of the *readf* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# readfi

readfi — Read a line of text from an external file.

## Description

Read a line of text from an external file once on initialisation.

## Syntax

```
Sres, iline readfi ifilename
```

## Initialization

*filename* -- an integer N denoting a file named "input.N" or a character string (in double quotes, spaces permitted) denoting the external file name. For a string, it may either be a full path name with directory specified or a simple filename. In the later case, the file is sought first in the current directory, then in SSDIR, and finally in SFDIR.

*iline* -- line number, or -1 when end of file has been reached.

*Sres* -- output of the line read from *filename*.

This opcode allows a line of text to be read from a named external file. There may be any number of *readfi* opcodes in an instrument or orchestra but they read separately from the same or different files.

## Examples

Here is an example of the *readfi* opcode. It uses the file *readfi.csd* [examples/readfi.csd].

### Example 743. Example of the *readfi* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# readk

readk — Periodically reads an orchestra control-signal value from an external file.

## Description

Periodically reads an orchestra control-signal value from a named external file in a specific format.

## Syntax

```
kres readk ifilename, iformat, iprd
```

## Initialization

*filename* -- an integer N denoting a file named "readk.N" or a character string (in double quotes, spaces permitted) denoting the external file name. For a string, it may either be a full path name with directory specified or a simple filename. In the later case, the file is sought first in the current directory, then in SSDIR, and finally in SFDIR.

*iformat* -- specifies the input data format:

- 1 = 8-bit signed integers (char)
- 4 = 16-bit short integers
- 5 = 32-bit long integers
- 6 = 32-bit floats
- 7 = ASCII long integers (plain text)
- 8 = ASCII floats (plain text)

Note that A-law and U-law formats are not available, and that all formats except the last two are binary. The input file should be a "raw", headerless data file.

*iprd* -- the rate (period) in seconds, rounded to the nearest orchestra control period, at which the signal is read from the input file. A value of 0 implies one control period (the enforced minimum), which will read new values at the orchestra control rate. Longer periods will cause the same values to repeat for more than one control period.

## Performance

*kres* -- output of the signal read from *filename*.

This opcode allows a generated control signal value to be read from a named external file. The file should contain no header information but it should contain a regularly sampled time series of control values. For ASCII text formats, the values are assumed to be separated by at least one whitespace character. There may be any number of *readk* opcodes in an instrument or orchestra and they may read from the same or different files.

# Examples

Here is an example of the readk opcode. It uses the file *readk.csd* [examples/readk.csd].

## Example 744. Example of the readk opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## readk2

readk2 — Periodically reads two orchestra control-signal values from an external file.

### Description

Periodically reads two orchestra control-signal values from an external file.

### Syntax

```
kr1, kr2 readk2 ifilename, iformat, iprd
```

### Initialization

*filename* -- an integer N denoting a file named "readk.N" or a character string (in double quotes, spaces permitted) denoting the external file name. For a string, it may either be a full path name with directory specified or a simple filename. In the later case, the file is sought first in the current directory, then in *SSDIR*, and finally in *SFDIR*.

*iformat* -- specifies the input data format:

- 1 = 8-bit signed integers (char)
- 4 = 16-bit short integers
- 5 = 32-bit long integers
- 6 = 32-bit floats
- 7 = ASCII long integers (plain text)
- 8 = ASCII floats (plain text)

Note that A-law and U-law formats are not available, and that all formats except the last two are binary. The input file should be a "raw", headerless data file.

*iprd* -- the rate (period) in seconds, rounded to the nearest orchestra control period, at which the signals are read from the input file. A value of 0 implies one control period (the enforced minimum), which will read new values at the orchestra control rate. Longer periods will cause the same values to repeat for more than one control period.

### Performance

*kr1, kr2* -- output of the signals read from *filename*.

This opcode allows two generated control signal values to be read from a named external file. The file should contain no header information but it should contain a regularly sampled time series of control values. For binary formats, the individual samples of each signal are interleaved. For ASCII text formats, the values are assumed to be separated by at least one whitespace character. The two "channels" in a sample frame may be on the same line or separated by newline characters, it does not matter. There may be any number of *readk2* opcodes in an instrument or orchestra and they may read from the same or

different files.

## Examples

Here is an example of the readk2 opcode. It uses the file *readk2.csd* [examples/readk2.csd].

### Example 746. Example of the readk2 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# readk3

readk3 — Periodically reads three orchestra control-signal values from an external file.

## Description

Periodically reads three orchestra control-signal values from an external file.

## Syntax

```
kr1, kr2, kr3 readk3 ifilename, iformat, iprd
```

## Initialization

*filename* -- an integer N denoting a file named "readk.N" or a character string (in double quotes, spaces permitted) denoting the external file name. For a string, it may either be a full path name with directory specified or a simple filename. In the later case, the file is sought first in the current directory, then in *SSDIR*, and finally in *SFDIR*.

*iformat* -- specifies the input data format:

- 1 = 8-bit signed integers (char)
- 4 = 16-bit short integers
- 5 = 32-bit long integers
- 6 = 32-bit floats
- 7 = ASCII long integers (plain text)
- 8 = ASCII floats (plain text)

Note that A-law and U-law formats are not available, and that all formats except the last two are binary. The input file should be a "raw", headerless data file.

*iprd* -- the rate (period) in seconds, rounded to the nearest orchestra control period, at which the signals are read from the input file. A value of 0 implies one control period (the enforced minimum), which will read new values at the orchestra control rate. Longer periods will cause the same values to repeat for more than one control period.

## Performance

*kr1, kr2, kr3* -- output of the signals read from *filename*.

This opcode allows three generated control signal values to be read from a named external file. The file should contain no header information but it should contain a regularly sampled time series of control values. For binary formats, the individual samples of each signal are interleaved. For ASCII text formats, the values are assumed to be separated by at least one whitespace character. The three "channels" in a sample frame may be on the same line or separated by newline characters, it does not matter. There may be any number of *readk3* opcodes in an instrument or orchestra and they may read from the

same or different files.

## Examples

Here is an example of the readk3 opcode. It uses the file *readk3.csd* [examples/readk3.csd].

### Example 747. Example of the readk3 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## readk4

readk4 — Periodically reads four orchestra control-signal values from an external file.

## Description

Periodically reads four orchestra control-signal values from an external file.

## Syntax

```
kr1, kr2, kr3, kr4 readk4 ifilename, iformat, iprd
```

## Initialization

*filename* -- an integer N denoting a file named "readk.N" or a character string (in double quotes, spaces permitted) denoting the external file name. For a string, it may either be a full path name with directory specified or a simple filename. In the later case, the file is sought first in the current directory, then in *SSDIR*, and finally in *SFDIR*.

*iformat* -- specifies the input data format:

- 1 = 8-bit signed integers (char)
- 4 = 16-bit short integers
- 5 = 32-bit long integers
- 6 = 32-bit floats
- 7 = ASCII long integers (plain text)
- 8 = ASCII floats (plain text)

Note that A-law and U-law formats are not available, and that all formats except the last two are binary. The input file should be a "raw", headerless data file.

*iprd* -- the rate (period) in seconds, rounded to the nearest orchestra control period, at which the signals are read from the input file. A value of 0 implies one control period (the enforced minimum), which will read new values at the orchestra control rate. Longer periods will cause the same values to repeat for more than one control period.

## Performance

*kr1, kr2, kr3, kr4* -- output of the signals read from *filename*.

This opcode allows four generated control signal values to be read from a named external file. The file should contain no header information but it should contain a regularly sampled time series of control values. For binary formats, the individual samples of each signal are interleaved. For ASCII text formats, the values are assumed to be separated by at least one whitespace character. The four "channels" in a sample frame may be on the same line or separated by newline characters, it does not matter. There may be any number of *readk4* opcodes in an instrument or orchestra and they may read from the

same or different files.

## Examples

Here is an example of the readk4 opcode. It uses the file *readk4.csd* [examples/readk4.csd].

### Example 748. Example of the readk4 opcode.

# readscore

readscore — Read, preprocess and schedule a score from an input string.

## Description

Readscore will issue one or more score events. It can handle strings in the same conditions as the standard score, including preprocessing (carry, sort, ramp, etc). Multi-line strings are accepted, using {{ }} to enclose the string.

## Syntax

```
readscore Sin
```

## Initialization

“*Sin*” -- a string (in double-quotes or enclosed by {{ }}) containing one or more score events.

## Examples

Here is an example of the readscore opcode. It uses the file *readscore.csd* [examples/readscore.csd].

### Example 749. Example of the readscore opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
-d -o dac
</CsOptions>
<CsInstruments>

instr 1
a1 flooper2 1000,p4,2,5,0.1,1
    out a1
endin

instr 2
ires readscore {{
{12 COUNT
i1 $COUNT 1 [1 + $COUNT/12]
}
}}
endin

</CsInstruments>
<CsScore>
f0 12
f 1 0 0 1 "fox.wav" 0 0 1
i2 0 1

</CsScore>
</CsoundSynthesizer>
```

You can use string opcodes like *sprintfk* to produce strings to be passed to *readscore* like this:

```
Sfil = "/Volumes/Bla/file.aif"
String sprintfk {{i 2 0 %f "%s" %f %f %f %f}}, idur, Sfil, p5, p6, knorm, iskip
readscore String
```

# readscratch

readscratch — returns a value stored in the instance of an instrument.

## Description

The *readscratch* opcode returns one of four scalar values stored in the instance of an instrument.

## Syntax

```
ival readscratch[index]
```

## Initialisation

*ival* -- variable for result.

*index* -- which value to read, defaulting to zero.

## Examples

Here is an example of the *readscratch* opcode. It uses the file *readscratch.csd* [examples/readscratch.csd].

### Example 750. Example of the readscratch opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# rect2pol

rect2pol — Rectangular to polar format conversion.

## Description

Converts an input array in real-imaginary format to magnitude-phase format.

## Syntax

```
kout[] rect2pol kin[]
```

## Performance

*kout[]* -- output array containing the complex-valued magnitude-phase output. It will be created if it does not exist.

*kin[]* -- input array containing the complex-valued real-imaginary input.

## Examples

Here is an example of the rect2pol opcode. It uses the file *rect2pol.csd* [examples/rect2pol.csd].

### Example 751. Example of the rect2pol opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# reinit

reinit — Suspends a performance while a special initialization pass is executed.

## Description

Suspends a performance while a special initialization pass is executed.

Whenever this statement is encountered during a p-time pass, performance is temporarily suspended while a special Initialization pass, beginning at *label* and continuing to *rireturn* or *endin*, is executed. Performance will then be resumed from where it left off.

## Syntax

```
reinit label
```

## Examples

The following statements will generate an exponential control signal whose value moves from 440 to 880 exactly ten times over the duration p3. They use the file *reinit.csd* [examples/reinit.csd].

### Example 752. Example of the reinit opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# release

*release* — Indicates whether a note is in its “release” stage.

## Description

Provides a way of knowing when a note off message for the current note is received. Only a noteoff message with the same MIDI note number as the one which triggered the note will be reported by *release*.

## Syntax

```
kflag release
```

## Performance

*kflag* -- indicates whether the note is in its “release” stage. (1 if a note off is received, otherwise 0)

*release* outputs current note state. If current note is in the “release” stage (i.e. if its duration has been extended with *xtratim* opcode and if it has only just deactivated), then the *kflag* output argument is set to 1. Otherwise (in sustain stage of current note), *kflag* is set to 0.

This opcode is useful for implementing complex release-oriented envelopes. When used in conjunction with *xtratim* it can provide an alternative to the hard-coded behaviour of the "r" opcodes (*linsegr*, *expseg* et al), where release time is set to the longest time specified in the active instrument.

## Examples

See the examples for *xtratim*.

# remoteport

remoteport — Defines the port for use with the remote system.

## Description

Defines the port for use with the *insremot*, *midremot*, *insglobal* and *midglobal* opcodes.

## Syntax

```
remoteport iportnum
```

## Initialization

*iportnum* -- number of the port to be used. If zero or negative the default port 40002 is selected.

## Credits

Author: John ffitch  
University of Bath/Codemist Ltd.  
Bath, UK  
November, 2006

New in Csound version 5.05

## remove

`remove` — Removes the definition of an instrument.

## Description

Removes the definition of an instrument as long as it is not in use.

## Syntax

```
remove insnum
```

## Initialization

*insnum* -- number or name of the instrument to be deleted

## Performance

As long as the indicated instrument is not active, *remove* deletes the instrument and memory associated with it. It should be treated with care as it is possible that in some cases its use may lead to a crash.

# repluck

repluck — Physical model of the plucked string.

## Description

*repluck* is an implementation of the physical model of the plucked string. A user can control the pluck point, the pickup point, the filter, and an additional audio signal, *axcite*. *axcite* is used to excite the 'string'. Based on the Karplus-Strong algorithm.

## Syntax

```
ares repluck iplk, kamp, icps, kpick, krefl, axcite
```

## Initialization

*iplk* -- The point of pluck is *iplk*, which is a fraction of the way up the string (0 to 1). A pluck point of zero means no initial pluck.

*icps* -- The string plays at *icps* pitch.

## Performance

*kamp* -- Amplitude of note.

*kpick* -- Proportion of the way along the string to sample the output.

*krefl* -- the coefficient of reflection, indicating the lossiness and the rate of decay. It must be strictly between 0 and 1 (it will complain about both 0 and 1).

## Performance

*axcite* -- A signal which excites the string.

## Examples

Here is an example of the repluck opcode. It uses the file *repluck.csd* [examples/repluck.csd].

### Example 753. Example of the repluck opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# reson

reson — A second-order resonant filter.

## Description

A second-order resonant filter.

## Syntax

```
ares reson asig, xcf, xbw [, iscl] [, iskip]
```

## Initialization

*iscl* (optional, default=0) -- coded scaling factor for resonators. A value of 1 signifies a peak response factor of 1, i.e. all frequencies other than *kcf* are attenuated in accordance with the (normalized) response curve. A value of 2 raises the response factor so that its overall RMS value equals 1. (This intended equalization of input and output power assumes all frequencies are physically present; hence it is most applicable to white noise.) A zero value signifies no scaling of the signal, leaving that to some later adjustment (see *balance*). The default value is 0.

*iskip* (optional, default=0) -- initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*ares* -- the output signal at audio rate.

*asig* -- the input signal at audio rate.

*xcf* -- the center frequency of the filter, or frequency position of the peak response.

*xbw* -- bandwidth of the filter (the Hz difference between the upper and lower half-power points).

*reson* is a second-order filter in which *kcf* controls the center frequency, or frequency position of the peak response, and *kbw* controls its bandwidth (the frequency difference between the upper and lower half-power points).

## Examples

Here is an example of the reson opcode. It uses the file *reson.csd* [examples/reson.csd].

### Example 754. Example of the reson opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# resonk

resonk — A second-order resonant filter.

## Description

A second-order resonant filter.

## Syntax

```
kres resonk ksig, kcf, kbw [, iscl] [, iskip]
```

## Initialization

*iscl* (optional, default=0) -- coded scaling factor for resonators. A value of 1 signifies a peak response factor of 1, i.e. all frequencies other than *kcf* are attenuated in accordance with the (normalized) response curve. A value of 2 raises the response factor so that its overall RMS value equals 1. (This intended equalization of input and output power assumes all frequencies are physically present; hence it is most applicable to white noise.) A zero value signifies no scaling of the signal, leaving that to some later adjustment (see *balance*). The default value is 0.

*iskip* (optional, default=0) -- initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*kres* -- the output signal at control-rate.

*ksig* -- the input signal at control-rate.

*kcf* -- the center frequency of the filter, or frequency position of the peak response.

*kbw* -- bandwidth of the filter (the Hz difference between the upper and lower half-power points).

*resonk* is like *reson* except its output is at control-rate rather than audio rate.

## Examples

Here is an example of the resonk opcode. It uses the file *resonk.csd* [examples/resonk.csd].

### Example 755. Example of the resonk opcode.

# resonr

resonr — A bandpass filter with variable frequency response.

## Description

Implementations of a second-order, two-pole two-zero bandpass filter with variable frequency response.

## Syntax

```
ares resonr asig, xcf, xbw [, iscl] [, iskip]
```

## Initialization

The optional initialization variables for *resonr* are identical to the i-time variables for *reson*.

*iscl* (optional, default=0) -- coded scaling factor for resonators. A value of 1 signifies a peak response factor of 1, i.e. all frequencies other than *kcf* are attenuated in accordance with the (normalized) response curve. A value of 2 raises the response factor so that its overall RMS value equals 1. This intended equalization of input and output power assumes all frequencies are physically present; hence it is most applicable to white noise. A zero value signifies no scaling of the signal, leaving that to some later adjustment (see *balance*). The default value is 0.

*iskip* (optional, default=0) -- initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*asig* -- input signal to be filtered

*xcf* -- cutoff or resonant frequency of the filter, measured in Hz

*xbw* -- bandwidth of the filter (the Hz difference between the upper and lower half-power points)

*resonr* and *resonz* are variations of the classic two-pole bandpass resonator (*reson*). Both filters have two zeroes in their transfer functions, in addition to the two poles. *resonz* has its zeroes located at  $z = 1$  and  $z = -1$ . *resonr* has its zeroes located at  $+\sqrt{R}$  and  $-\sqrt{R}$ , where  $R$  is the radius of the poles in the complex  $z$ -plane. The addition of zeroes to *resonr* and *resonz* results in the improved selectivity of the magnitude response of these filters at cutoff frequencies close to 0, at the expense of less selectivity of frequencies above the cutoff peak.

*resonr* and *resonz* are very close to constant-gain as the center frequency is swept, resulting in a more efficient control of the magnitude response than with traditional two-pole resonators such as *reson*.

*resonr* and *resonz* produce a sound that is considerably different from *reson*, especially for lower center frequencies; trial and error is the best way of determining which resonator is best suited for a particular application.

## Examples

Here is an example of the resonr and resonz opcodes. It uses the file *resonr.csd* [examples/resonr.csd].

**Example 756. Example of the resonr and resonz opcodes.**

## Technical History

*resonr* and *resonz* were originally described in an article by Julius O. Smith and James B. Angell.<sup>1</sup> Smith and Angell recommended the *resonz* form (zeros at +1 and -1) when computational efficiency was the main concern, as it has one less multiply per sample, while *resonr* (zeroes at + and - the square root of the pole radius R) was recommended for situations when a perfectly constant-gain center peak was required.

Ken Steiglitz, in a later article<sup>2</sup>, demonstrated that *resonz* had constant gain at the true peak of the filter, as opposed to *resonr*, which displayed constant gain at the pole angle. Steiglitz also recommended *resonz* for its sharper notches in the gain curve at zero and Nyquist frequency. Steiglitz's recent book<sup>3</sup> features a thorough technical discussion of *reson* and *resonz*, while Dodge and Jerse's textbook<sup>4</sup> illustrates the differences in the response curves of *reson* and *resonz*.

# resonx

resonx — Emulates a stack of filters using the reson opcode.

## Description

*resonx* is equivalent to a filters consisting of more layers of *reson* with the same arguments, serially connected. Using a stack of a larger number of filters allows a sharper cutoff. They are faster than using a larger number instances in a Csound orchestra of the old opcodes, because only one initialization and k-cycle are needed at time and the audio loop falls entirely inside the cache memory of processor.

## Syntax

```
ares resonx asig, xcf, xbw [, inumlayer] [, iscl] [, iskip]
```

## Initialization

*inumlayer* (optional) -- number of elements in the filter stack. Default value is 4.

*iscl* (optional, default=0) -- coded scaling factor for resonators. A value of 1 signifies a peak response factor of 1, i.e. all frequencies other than kcf are attenuated in accordance with the (normalized) response curve. A value of 2 raises the response factor so that its overall RMS value equals 1. (This intended equalization of input and output power assumes all frequencies are physically present; hence it is most applicable to white noise.) A zero value signifies no scaling of the signal, leaving that to some later adjustment (see *balance*). The default value is 0.

*iskip* (optional, default=0) -- initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*asig* -- input signal

*xcf* -- the center frequency of the filter, or frequency position of the peak response.

*xbw* -- bandwidth of the filter (the Hz difference between the upper and lower half-power points)

## Examples

Here is an example of the resonx opcodes. It uses the file *resonx.csd* [examples/resonx.csd].

# resonxk

`resonxk` — Control signal resonant filter stack.

## Description

`resonxk` is equivalent to a group of resonk filters, with the same arguments, serially connected. Using a stack of a larger number of filters allows a sharper cutoff.

## Syntax

```
kres resonxk ksig, kcf, kbw[, inumlayer, iscl, istor]
```

## Initialization

*inumlayer* - number of elements of filter stack. Default value is 4. Maximum value is 10

*iscl* (optional, default=0) - coded scaling factor for resonators. A value of 1 signifies a peak response factor of 1, i.e. all frequencies other than kcf are attenuated in accordance with the (normalized) response curve. A value of 2 raises the response factor so that its overall RMS value equals 1. (This intended equalization of input and output power assumes all frequencies are physically present; hence it is most applicable to white noise.) A zero value signifies no scaling of the signal, leaving that to some later adjustment (see balance). The default value is 0.

*istor* (optional, default=0) -- initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*kres* - output signal

*ksig* - input signal

*kcf* - the center frequency of the filter, or frequency position of the peak response.

*kbw* - bandwidth of the filter (the Hz difference between the upper and lower half-power points)

`resonxk` is a lot faster than using individual instances in Csound orchestra of the old opcodes, because only one initialization and 'k' cycle are needed at a time, and the audio loop falls entirely inside the cache memory of processor.

## Examples

Here is an example of the `resonxk` opcode. It uses the file `resonxk.csd` [examples/resonxk.csd].

### Example 758. Example of the `resonxk` opcode.

# resony

resony — A bank of second-order bandpass filters, connected in parallel.

## Description

A bank of second-order bandpass filters, connected in parallel.

## Syntax

```
ares resony asig, kbf, kbw, inum, ksep [, isepmode] [, iscl] [, iskip]
```

## Initialization

*inum* -- number of filters

*isepmode* (optional, default=0) -- if *isepmode* = 0, the separation of center frequencies of each filter is generated logarithmically (using octave as unit of measure). If *isepmode* not equal to 0, the separation of center frequencies of each filter is generated linearly (using Hertz). Default value is 0.

*iscl* (optional, default=0) -- coded scaling factor for resonators. A value of 1 signifies a peak response factor of 1, i.e. all frequencies other than *kcf* are attenuated in accordance with the (normalized) response curve. A value of 2 raises the response factor so that its overall RMS value equals 1. (This intended equalization of input and output power assumes all frequencies are physically present; hence it is most applicable to white noise.) A zero value signifies no scaling of the signal, leaving that to some later adjustment (e.g. *balance*). The default value is 0.

*iskip* (optional, default=0) -- initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*asig* -- audio input signal

*kbf* -- base frequency, i.e. center frequency of lowest filter in Hz

*kbw* -- bandwidth in Hz

*ksep* -- separation of the center frequency of filters in octaves

*resony* is a bank of second-order bandpass filters, with k-rate variant frequency separation, base frequency and bandwidth, connected in parallel (i.e. the resulting signal is a mix of the output of each filter). The center frequency of each filter depends of *kbf* and *ksep* variables. The maximum number of filters is set to 100.

## Examples

Here is an example of the resony opcode. It uses the file *resony.csd* [examples/resony.csd].

## resonz

*resonz* — A bandpass filter with variable frequency response.

## Description

Implementations of a second-order, two-pole two-zero bandpass filter with variable frequency response.

## Syntax

```
ares resonz asig, xcf, xbw [, iscl] [, iskip]
```

## Initialization

The optional initialization variables for *resonr* and *resonz* are identical to the i-time variables for *reson*.

*iskip* -- initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

*iscl* -- coded scaling factor for resonators. A value of 1 signifies a peak response factor of 1, i.e. all frequencies other than *kcf* are attenuated in accordance with the (normalized) response curve. A value of 2 raises the response factor so that its overall RMS value equals 1. This intended equalization of input and output power assumes all frequencies are physically present; hence it is most applicable to white noise. A zero value signifies no scaling of the signal, leaving that to some later adjustment (see *balance*). The default value is 0.

## Performance

*resonr* and *resonz* are variations of the classic two-pole bandpass resonator (*reson*). Both filters have two zeroes in their transfer functions, in addition to the two poles. *resonz* has its zeroes located at  $z = 1$  and  $z = -1$ . *resonr* has its zeroes located at  $+\sqrt{R}$  and  $-\sqrt{R}$ , where  $R$  is the radius of the poles in the complex z-plane. The addition of zeroes to *resonr* and *resonz* results in the improved selectivity of the magnitude response of these filters at cutoff frequencies close to 0, at the expense of less selectivity of frequencies above the cutoff peak.

*resonr* and *resonz* are very close to constant-gain as the center frequency is swept, resulting in a more efficient control of the magnitude response than with traditional two-pole resonators such as *reson*.

*resonr* and *resonz* produce a sound that is considerably different from *reson*, especially for lower center frequencies; trial and error is the best way of determining which resonator is best suited for a particular application.

*asig* -- input signal to be filtered

*xcf* -- cutoff or resonant frequency of the filter, measured in Hz

*xbw* -- bandwidth of the filter (the Hz difference between the upper and lower half-power points)

## Technical History

*resonr* and *resonz* were originally described in an article by Julius O. Smith and James B. Angell.<sup>1</sup>

Smith and Angell recommended the *resonz* form (zeros at +1 and -1) when computational efficiency was the main concern, as it has one less multiply per sample, while *resonr* (zeroes at + and - the square root of the pole radius R) was recommended for situations when a perfectly constant-gain center peak was required.

Ken Steiglitz, in a later article<sup>2</sup>, demonstrated that *resonz* had constant gain at the true peak of the filter, as opposed to *resonr*, which displayed constant gain at the pole angle. Steiglitz also recommended *resonz* for its sharper notches in the gain curve at zero and Nyquist frequency. Steiglitz's recent book<sup>3</sup> features a thorough technical discussion of *reson* and *resonz*, while Dodge and Jerse's textbook<sup>4</sup> illustrates the differences in the response curves of *reson* and *resonz*.

## Examples

Here is an example of the *resonr* and *resonz* opcodes. It uses the file *resonr.csd* [examples/resonr.csd].

# resyn

resyn — Streaming partial track additive synthesis with cubic phase interpolation with pitch control and support for timescale-modified input

## Description

The resyn opcode takes an input containing a TRACKS pv streaming signal (as generated, for instance by partials). It resynthesises the signal using linear amplitude and cubic phase interpolation to drive a bank of interpolating oscillators with amplitude and pitch scaling controls. Resyn is a modified version of sinsyn, allowing for the resynthesis of data with pitch and timescale changes.

## Syntax

```
asig resyn fin, kscal, kpitch, kmaxtracks, ifn
```

## Performance

*asig* -- output audio rate signal

*fin* -- input pv stream in TRACKS format

*kscal* -- amplitude scaling

*kpitch* -- pitch scaling

*kmaxtracks* -- max number of tracks in resynthesis. Limiting this will cause a non-linear filtering effect, by discarding newer and higher-frequency tracks (tracks are ordered by start time and ascending frequency, respectively)

*ifn* -- function table containing one cycle of a sinusoid (sine or cosine)

## Examples

Here is an example of the resyn opcode. It uses the file *resyn.csd* [examples/resyn.csd].

### Example 761. Example of the resyn opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# return

`return` — Returns a value from an instrument.

## Description

`Return` will return a value from an instrument at i-time. The value of a global instrument (instrument 0) can be retrieved after compilation by the `evalstr` opcode. The retrieval of values returned by other instruments is not yet implemented.

## Syntax

```
return ival
```

## Initialization

“*ival*” -- a value to be returned by instrument.

## Examples

Here is an example of the `return` opcode in conjunction with `evalcode`:

### Example 762.

```
ival evalstr "return 2 + 2"  
print ival
```

## Credits

Author: Victor Lazzarini, 2013

# reverb

reverb — Reverberates an input signal with a “natural room” frequency response.

## Description

Reverberates an input signal with a “natural room” frequency response.

## Syntax

```
ares reverb asig, krvt [, iskip]
```

## Initialization

*iskip* (optional, default=0) -- initial disposition of delay-loop data space (cf. *reson*). The default value is 0.

## Performance

*krvt* -- the reverberation time (defined as the time in seconds for a signal to decay to 1/1000, or 60dB down from its original amplitude).

A standard *reverb* unit is composed of four *comb* filters in parallel followed by two *alpass* units in series. Loop times are set for optimal “natural room response.” Core storage requirements for this unit are proportional only to the sampling rate, each unit requiring approximately 3K words for every 10KC. The *comb*, *alpass*, *delay*, *tone* and other Csound units provide the means for experimenting with alternate reverberator designs.

Since output from the standard *reverb* will begin to appear only after 1/20 second or so of delay, and often with less than three-fourths of the original power, it is normal to output both the source and the reverberated signal. If *krvt* is inadvertently set to a non-positive number, *krvt* will be reset automatically to 0.01. (New in Csound version 4.07.) Also, since the reverberated sound will persist long after the cessation of source events, it is normal to put *reverb* in a separate instrument to which sound is passed via a *global variable*, and to leave that instrument running throughout the performance.

## Examples

Here is an example of the *reverb* opcode. It uses the file *reverb.csd* [examples/reverb.csd].

### Example 763. Example of the reverb opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## reverb2

reverb2 — Same as the *nreverb* opcode.

### Description

Same as the *nreverb* opcode.

### Syntax

```
ares reverb2 asig, ktime, khdif [, iskip] [,inumCombs] \
[, ifnCombs] [, inumAlpas] [, ifnAlpas]
```

# reverbsc

reverbsc — 8 delay line stereo FDN reverb, based on work by Sean Costello

## Description

8 delay line stereo FDN reverb, with feedback matrix based upon physical modeling scattering junction of 8 lossless waveguides of equal characteristic impedance. Based on Csound orchestra version by Sean Costello.

## Syntax

```
aoutL, aoutR reverbsc ainL, ainR, ktblvl, kfco[, israte[, ipitchm[, iskip]]]
```

## Initialization

*israte* (optional, defaults to the orchestra sample rate) -- assume a sample rate of *israte*. This is normally set to *sr*, but a different setting can be useful for special effects.

*ipitchm* (optional, defaults to 1) -- depth of random variation added to delay times, in the range 0 to 10. The default is 1, but this may be too high and may need to be reduced for held pitches such as piano tones.

*iskip* (optional, defaults to zero) -- if non-zero, initialization of the opcode is skipped, whenever possible.

## Performance

*aoutL, aoutR* -- output signals for left and right channel

*ainL, ainR* -- left and right channel input. Note that having an input signal on either the left or right channel only will still result in having reverb output on both channels, making this unit more suitable for reverberating stereo input than the freeverb opcode.

*ktblvl* -- feedback level, in the range 0 to 1. 0.6 gives a good small "live" room sound, 0.8 a small hall, and 0.9 a large hall. A setting of exactly 1 means infinite length, while higher values will make the opcode unstable.

*kfco* -- cutoff frequency of simple first order lowpass filters in the feedback loop of delay lines, in Hz. Should be in the range 0 to *israte*/2 (not *sr*/2). A lower value means faster decay in the high frequency range.

## Examples

Here is an example of the *reverbsc* opcode. It uses the file *reverbsc.csd* [examples/reverbsc.csd].

### Example 764. An example of the reverbsc opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# rezzy

*rezzy* — A resonant low-pass filter.

## Description

A resonant low-pass filter.

## Syntax

```
ares rezzy asig, xfco, xres [, imode, iskip]
```

## Initialization

*imode* (optional, default=0) -- high-pass or low-pass mode. If zero, *rezzy* is low-pass. If not zero, *rezzy* is high-pass. Default value is 0. (New in Csound version 3.50)

*iskip* (optional, default=0) -- if non zero skip the initialisation of the filter. (New in Csound version 4.23f13 and 5.0)

## Performance

*asig* -- input signal

*xfco* -- filter cut-off frequency in Hz. As of version 3.50, may i-,k-, or a-rate.

*xres* -- amount of resonance. Values of 1 to 100 are typical. Resonance should be one or greater. As of version 3.50, may a-rate, i-rate, or k-rate.

*rezzy* is a resonant low-pass filter created empirically by Hans Mikelson.

## Examples

Here is an example of the *rezzy* opcode. It uses the file *rezzy.csd* [examples/rezzy.csd].

### Example 766. Example of the rezzy opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# rfft

rfft — Fast Fourier Transform of a real-value array.

## Description

Applies a forward Fast Fourier Transform to a real-value input 1-dimensional array. The output is another array containing the transform, non-redundant, non-negative spectrum only. If the input array is power-of-two, the output array size will match the input size, with the first two points containing 0Hz and Nyquist frequency coefficients. Otherwise, the output will have two extra values (input size + 2), and the the Nyquist coefficient will be placed at kin[input\_size] position (kin[1] and kin[input\_size+1] will be 0).

## Syntax

```
kout[] rfft kin[]
```

## Performance

*kout[]* -- output array containing the transform. It will be created if it does not exist.

*kin[]* -- input array containing the real-valued input.

## Examples

Here is an example of the rfft opcode. It uses the file *rfft.csd* [examples/rfft.csd].

### Example 767. Example of the rfft opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# rigoto

`rigoto` — Transfers control during a *reinit* pass.

## Description

Similar to *igoto*, but effective only during a *reinit* pass (i.e., no-op at standard i-time). This statement is useful for bypassing units that are not to be reinitialized.

## Syntax

```
rigoto label
```

## See Also

*cigoto*, *igoto*, *reinit*, *rireturn*

# rireturn

rireturn — Terminates a reinit pass.

## Description

Terminates a *reinit* pass (i.e., no-op at standard i-time). This statement, or an *endin*, will cause normal performance to be resumed.

## Syntax

```
rireturn
```

## Examples

The following statements will generate an exponential control signal whose value moves from 440 to 880 exactly ten times over the duration p3. They use the file *reinit.csd* [examples/reinit.csd].

### Example 769. Example of the rireturn opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

`rms` — Determines the root-mean-square amplitude of an audio signal.

## Description

Determines the root-mean-square amplitude of an audio signal. It low-pass filters the actual value, to average in the manner of a VU meter.

## Syntax

```
kres rms asig [, ihp] [, iskip]
```

## Initialization

*ihp* (optional, default=10) -- half-power point (in Hz) of a special internal low-pass filter. The default value is 10.

*iskip* (optional, default=0) -- initial disposition of internal data space (see *reson*). The default value is 0.

## Performance

*asig* -- input audio signal

*kres* -- low-pass filtered rms value of the input signal

*rms* output values *kres* will trace the root-mean-square value of the audio input *asig*. This unit is not a signal modifier, but functions rather as a signal power-gauge. It uses an internal low-pass filter to make the response smoother. *ihp* can be used to control this smoothing. The higher the value, the "snappier" the measurement.

This opcode can also be used as an envelope follower.

The *kres* output from this opcode is given in amplitude and depends on *0dbfs*. If you want the output in decibels, you can use *dbamp*

## Examples

```
arms rms      asig ; get rms value of signal asig
```

Here is an example of the *rms* opcode. It uses the file *rms.csd* [examples/rms.csd].

### Example 770. Example of the rms opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# rnd

rnd — Returns a random number in a unipolar range at the rate given by the input argument.

## Description

Returns a random number in a unipolar range at the rate given by the input argument.

## Syntax

```
rnd(x) (init- or control-rate only)
```

Where the argument within the parentheses may be an expression. These value converters sample a global random sequence, but do not reference *seed*. The result can be a term in a further expression.

## Performance

Returns a random number in the unipolar range 0 to *x*.

## Examples

Here is an example of the rnd opcode. It uses the file *rnd.csd* [examples/rnd.csd].

### Example 771. Example of the rnd opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# rnd31

`rnd31` — 31-bit bipolar random opcodes with controllable distribution.

## Description

31-bit bipolar random opcodes with controllable distribution. These units are portable, i.e. using the same seed value will generate the same random sequence on all systems. The distribution of generated random numbers can be varied at k-rate.

## Syntax

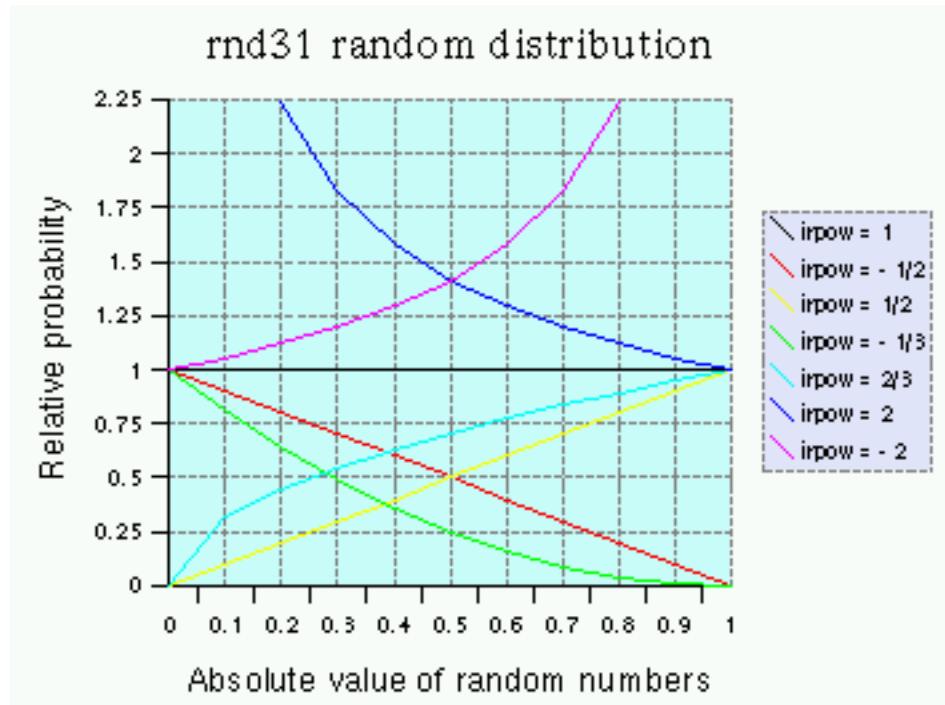

```
ax rnd31 kscl, kpow [, iseed]  
ix rnd31 iscl, irpow [, iseed]  
kx rnd31 kscl, kpow [, iseed]
```

## Initialization

*ix* -- i-rate output value.

*iscl* -- output scale. The generated random numbers are in the range -*iscl* to *iscl*.

*irpow* -- controls the distribution of random numbers. If *irpow* is positive, the random distribution ( $x$  is in the range -1 to 1) is  $\text{abs}(x)^{\wedge}((1 / \text{irpow}) - 1)$ ; for negative *irpow* values, it is  $(1 - \text{abs}(x))^{\wedge}((-1 / \text{irpow}) - 1)$ . Setting *irpow* to -1, 0, or 1 will result in uniform distribution (this is also faster to calculate).

A graph of distributions for different values of irpow.

*iseed* (optional, default=0) -- seed value for random number generator (positive integer in the range 1 to 2147483646 ( $2^{31} - 2$ )). Zero or negative value seeds from current time (this is also the default). Seeding from current time is guaranteed to generate different random sequences, even if multiple random opcodes are called in a very short time.

In the a- and k-rate version the seed is set at opcode initialization. With i-rate output, if *iseed* is zero or negative, it will seed from current time in the first call, and return the next value from the random sequence in successive calls; positive seed values are set at all i-rate calls. The seed is local for a- and k-rate, and global for i-rate units.

## Notes

- although seed values up to 2147483646 are allowed, it is recommended to use smaller numbers (< 1000000) for portability, as large integers may be rounded to a different value if 32-bit floats are used.
- i-rate *rnd31* with a positive seed will always produce the same output value (this is not a bug). To get different values, set seed to 0 in successive calls, which will return the next value from the random sequence.

## Performance

*ax* -- a-rate output value.

*kx* -- k-rate output value.

*kscl* -- output scale. The generated random numbers are in the range -*kscl* to *kscl*. It is the same as *iscl*, but can be varied at k-rate.

*krpow* -- controls the distribution of random numbers. It is the same as *irpow*, but can be varied at k-rate.

## Examples

Here is an example of the *rnd31* opcode at a-rate. It uses the file *rnd31.csd* [examples/rnd31.csd].

# round

round — Returns the integer value nearest to  $x$  ; if the fractional part of  $x$  is exactly 0.5, the direction of rounding is undefined.

## Description

The integer value nearest to  $x$  ; if the fractional part of  $x$  is exactly 0.5, the direction of rounding is undefined.

## Syntax

```
round(x) (init-, control-, or audio-rate arg allowed)
```

where the argument within the parentheses may be an expression. Value converters perform arithmetic translation from units of one kind to units of another. The result can then be a term in a further expression.

## Examples

Here is an example of the round opcode. It uses the file *round.csd* [examples/round.csd].

### Example 776. Example of the round opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# rspline

rspline — Generate random spline curves.

## Description

Generate random spline curves.

## Syntax

```
ares rspline xrangeMin, xrangeMax, kcpsMin, kcpsMax
```

```
kres rspline krangleMin, krangleMax, kcpsMin, kcpsMax
```

## Performance

*kres, ares* -- Output signal

*xrangeMin, xrangeMax* -- Range of values of random-generated points

*kcpsMin, kcpsMax* -- Range of point-generation rate. Min and max limits are expressed in cps.

*rspline* (random-spline-curve generator) is similar to *jspline* but output range is defined by means of two limit values. Also in this case, real output range could be a bit greater of range values, because of interpolating curves between each pair of random-points.

At present time generated curves are quite smooth when *cpsMin* is not too different from *cpsMax*. When *cpsMin-cpsMax* interval is big, some little discontinuity could occur, but it should not be a problem, in most cases. Maybe the algorithm will be improved in next versions.

These opcodes are often better than *jitter* when user wants to “naturalize” or “analogize” digital sounds. They could be used also in algorithmic composition, to generate smooth random melodic lines when used together with *samphold* opcode.

Note that the result is quite different from the one obtained by filtering white noise, and they allow the user to obtain a much more precise control.

## Examples

Here is an example of the rspline opcode. It uses the file *rspline.csd* [examples/rspline.csd].

### Example 777. Example of the rspline opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# s16b14

*s16b14* — Creates a bank of 16 different 14-bit MIDI control message numbers.

## Description

Creates a bank of 16 different 14-bit MIDI control message numbers.

## Syntax

```
i1,...,i16 s16b14 ichan, ictlno_msbl, ictlno_lsb1, imin1, imax1, \
initvalue1, ifn1,..., ictlno_msbl6, ictlno_lsb16, imin16, imax16, initvalue16, ifn16

k1,...,k16 s16b14 ichan, ictlno_msbl, ictlno_lsb1, imin1, imax1, \
initvalue1, ifn1,..., ictlno_msbl6, ictlno_lsb16, imin16, imax16, initvalue16, ifn16
```

## Initialization

*i1 ... i64* -- output values

*ichan* -- MIDI channel (1-16)

*ictlno\_msbl* .... *ictlno\_msbl32* -- MIDI control number, most significant byte (0-127)

*ictlno\_lsb1* .... *ictlno\_lsb32* -- MIDI control number, least significant byte (0-127)

*imin1* ... *imin64* -- minimum values for each controller

*imax1* ... *imax64* -- maximum values for each controller

*init1* ... *init64* -- initial value for each controller

*ifn1* ... *ifn64* -- function table for conversion for each controller

## Performance

*k1 ... k64* -- output values

*s16b14* is a bank of MIDI controllers, useful when using MIDI mixer such as Kawai MM-16 or others for changing whatever sound parameter in real-time. The raw MIDI control messages at the input port are converted to agree with *iminN* and *imaxN*, and an initial value can be set. Also, an optional non-interpolated function table with a custom translation curve is allowed, useful for enabling exponential response curves.

When no function table translation is required, set the *ifnN* value to 0, else set *ifnN* to a valid function table number. When table translation is enabled (i.e. setting *ifnN* value to a non-zero number referring to an already allocated function table), *initN* value should be set equal to *iminN* or *imaxN* value, else the initial output value will not be the same as specified in *initN* argument.

*s16b14* allows a bank of 16 different MIDI control message numbers. It uses 14-bit values instead of MIDI's normal 7-bit values.

As the input and output arguments are many, you can split the line using '\' (backslash) character (new in 3.47 version) to improve the readability. Using these opcodes is considerably more efficient than using

the separate ones (*ctrl7* and *tonek*) when more controllers are required.

In the i-rate version of *s16b14*, there is not an initial value input argument. The output is taken directly from the current status of internal controller array of Csound.

Thanks goes to Rasmus Ekman for pointing out the correct MIDI channel and controller number ranges.

# s32b14

s32b14 — Creates a bank of 32 different 14-bit MIDI control message numbers.

## Description

Creates a bank of 32 different 14-bit MIDI control message numbers.

## Syntax

```
i1,...,i32 s32b14 ichan, ictlno_msbl, ictlno_lsb1, imin1, imax1, \
initvalue1, ifn1,..., ictlno_msbl32, ictlno_lsb32, imin32, imax32, initvalue32, ifn32

k1,...,k32 s32b14 ichan, ictlno_msbl, ictlno_lsb1, imin1, imax1, \
initvalue1, ifn1,..., ictlno_msbl32, ictlno_lsb32, imin32, imax32, initvalue32, ifn32
```

## Initialization

*i1 ... i64* -- output values

*ichan* -- MIDI channel (1-16)

*ictlno\_msbl* .... *ictlno\_msbl32* -- MIDI control number, most significant byte (0-127)

*ictlno\_lsb1* .... *ictlno\_lsb32* -- MIDI control number, least significant byte (0-127)

*imin1* ... *imin64* -- minimum values for each controller

*imax1* ... *imax64* -- maximum values for each controller

*init1* ... *init64* -- initial value for each controller

*ifn1* ... *ifn64* -- function table for conversion for each controller

## Performance

*k1 ... k64* -- output values

*s32b14* is a bank of MIDI controllers, useful when using MIDI mixer such as Kawai MM-16 or others for changing whatever sound parameter in real-time. The raw MIDI control messages at the input port are converted to agree with *iminN* and *imaxN*, and an initial value can be set. Also, an optional non-interpolated function table with a custom translation curve is allowed, useful for enabling exponential response curves.

When no function table translation is required, set the *ifnN* value to 0, else set *ifnN* to a valid function table number. When table translation is enabled (i.e. setting *ifnN* value to a non-zero number referring to an already allocated function table), *initN* value should be set equal to *iminN* or *imaxN* value, else the initial output value will not be the same as specified in *initN* argument.

*s32b14* allows a bank of 32 different MIDI control message numbers. It uses 14-bit values instead of MIDI's normal 7-bit values.

As the input and output arguments are many, you can split the line using '\' (backslash) character (new in 3.47 version) to improve the readability. Using these opcodes is considerably more efficient than using

the separate ones (*ctrl7* and *tonek*) when more controllers are required.

In the i-rate version of *s32b14*, there is not an initial value input argument. The output is taken directly from the current status of internal controller array of Csound.

# samphold

samphold — Performs a sample-and-hold operation on its input.

## Description

Performs a sample-and-hold operation on its input.

## Syntax

```
ares samphold asig, agate [, ival] [, ivstor]
```

```
kres samphold ksig, kgate [, ival] [, ivstor]
```

## Initialization

*ival, ivstor* (optional) -- controls initial disposition of internal save space. If *ivstor* is zero the internal “hold” value is set to *ival*; else it retains its previous value. Defaults are 0,0 (i.e. init to zero)

## Performance

*kgate, xgate* -- controls whether to hold the signal.

*samphold* performs a sample-and-hold operation on its input according to the value of *gate*. If *gate != 0*, the input samples are passed to the output; if *gate = 0*, the last output value is repeated. The controlling *gate* can be a constant, a control signal, or an audio signal.

## Examples

```
asrc  buzz      10000, 440, 20, 1      ; band-limited pulse train
adif  diff       asrc
anew  balance   adif, asrc
agate reson     asrc, 0, 440
asamp samphold anew, agate
aout  tone       asamp, 100
                                ; emphasize the highs
                                ; but retain the power
                                ; use a lowpass of the original
                                ; to gate the new audiosig
                                ; smooth out the rough edges
```

Here is another example of the *samphold* opcode. It uses the file *samphold.csd* [examples/samphold.csd].

### Example 779. Example of the *samphold* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# sandpaper

`sandpaper` — Semi-physical model of a sandpaper sound.

## Description

`sandpaper` is a semi-physical model of a sandpaper sound. It is one of the PhISEM percussion opcodes. PhISEM (Physically Informed Stochastic Event Modeling) is an algorithmic approach for simulating collisions of multiple independent sound producing objects.

## Syntax

```
ares sandpaper iamp, idettack [, inum] [, idamp] [, imaxshake]
```

## Initialization

*iamp* -- Amplitude of output. Note: As these instruments are stochastic, this is only a approximation.

*idettack* -- period of time over which all sound is stopped

*inum* (optional) -- The number of beads, teeth, bells, timbrels, etc. If zero, the default value is 128.

*idamp* (optional) -- the damping factor, as part of this equation:

$$\text{damping\_amount} = 0.998 + (\text{idamp} * 0.002)$$

The default *damping\_amount* is 0.999 which means that the default value of *idamp* is 0.5. The maximum *damping\_amount* is 1.0 (no damping). This means the maximum value for *idamp* is 1.0.

The recommended range for *idamp* is usually below 75% of the maximum value.

*imaxshake* (optional) -- amount of energy to add back into the system. The value should be in range 0 to 1.

## Examples

Here is an example of the `sandpaper` opcode. It uses the file `sandpaper.csd` [examples/sandpaper.csd].

### Example 780. Example of the `sandpaper` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# scale

scale — Arbitrary signal scaling.

## Description

Scales incoming value to user-definable range. Similar to scale object found in popular dataflow languages.

## Syntax

```
kscl scale kinput, kmax, kmin
```

## Performance

*kin* -- Input value. Can originate from any k-rate source as long as that source's output is in range 0-1.

*kmin* -- Minimum value of the resultant scale operation.

*kmax* -- Maximum value of the resultant scale operation.

## Examples

Here is an example of the scale opcode. It uses the file *scale.csd* [examples/scale.csd].

### Example 781. Example of the scale opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# scalearray

scalearray — Scales the values in a range of a vector (one dimensional array).

## Description

The *scalearray* opcode scales a subregion of a vector to a given minimum/maximum.

## Syntax

```
scalearray tarray, kmin, kmax[, kleft, kright]
```

## Performance

*karray* -- array for operation.

*kmin, kmax* -- target minimum and maximum values.

*kleft, kright* -- range of table to use, defaulting to 0 and size of the vector.

## Examples

Here is an example of the *scalearray* opcode. It uses the file *scalearray.csd* [examples/scalearray.csd].

### Example 782. Example of the scalearray opcode.

# scanhammer

scanhammer — Copies from one table to another with a gain control.

## Description

This is a variant of *tablecopy*, copying from one table to another, starting at *ipos*, and with a gain control. The number of points copied is determined by the length of the source. Other points are not changed. This opcode can be used to “hit” a string in the scanned synthesis code.

## Syntax

```
scanhammer isrc, idst, ipos, imult
```

## Initialization

*isrc* -- source function table.

*idst* -- destination function table.

*ipos* -- starting position (in points).

*imult* -- gain multiplier. A value of 0 will leave values unchanged.

## See Also

*scantable*

# scans

`scans` — Generate audio output using scanned synthesis.

## Description

Generate audio output using scanned synthesis.

## Syntax

```
ares scans kamp, kfreq, ifn, id [, iorder]
```

## Initialization

*ifn* -- ftable containing the scanning trajectory. This is a series of numbers that contains addresses of masses. The order of these addresses is used as the scan path. It should not contain values greater than the number of masses, or negative numbers. See the *introduction to the scanned synthesis section*.

*id* -- ID number of the *scans* opcode's waveform to use

*iorder* (optional, default=0) -- order of interpolation used internally. It can take any value in the range 1 to 4, and defaults to 4, which is quartic interpolation. The setting of 2 is quadratic and 1 is linear. The higher numbers are slower, but not necessarily better.

## Performance

*kamp* -- output amplitude. Note that the resulting amplitude is also dependent on instantaneous value in the wavetable. This number is effectively the scaling factor of the wavetable.

*kfreq* -- frequency of the scan rate

## Examples

Here is an example of the scanned synthesis. It uses the file *scans.csd* [examples/scans.csd], and *string-128.matrix* [examples/string-128.matrix].

### Example 783. Example of the scans opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# scantable

scantable — A simpler scanned synthesis implementation.

## Description

A simpler scanned synthesis implementation. This is an implementation of a circular string scanned using external tables. This opcode will allow direct modification and reading of values with the table opcodes.

## Syntax

```
aout scantable kamp, kpch, ipos, imass, istiff, idamp, ivel
```

## Initialization

*ipos* -- table containing position array.

*imass* -- table containing the mass of the string.

*istiff* -- table containing the stiffness of the string.

*idamp* -- table containing the damping factors of the string.

*ivel* -- table containing the velocities.

## Performance

*kamp* -- amplitude (gain) of the string.

*kpch* -- the string's scanned frequency.

## Examples

Here is an example of the scantable opcode. It uses the file *scantable.csd* [examples/scantable.csd].

### Example 785. Example of the scantable opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# scnu

scnu — Compute the waveform and the wavetable for use in scanned synthesis.

## Description

Compute the waveform and the wavetable for use in scanned synthesis.

## Syntax

```
scnu init, irate, ifnvel, ifnmass, ifnstif, ifncentr, ifndamp, kmass, \
kstif, kcentr, kdamp, ileft, iright, kpos, kstrngth, ain, idisp, id
```

## Initialization

*init* -- the initial position of the masses. If this is a negative number, then the absolute of *init* signifies the table to use as a hammer shape. If *init* > 0, the length of it should be the same as the intended mass number, otherwise it can be anything.

*ifnvel* -- the ftable that contains the initial velocity for each mass. It should have the same size as the intended mass number.

*ifnmass* -- ftable that contains the mass of each mass. It should have the same size as the intended mass number.

*ifnstif* -- ftable that contains the spring stiffness of each connection. It should have the same size as the square of the intended mass number. The data ordering is a row after row dump of the connection matrix of the system.

*ifncentr* -- ftable that contains the centering force of each mass. It should have the same size as the intended mass number.

*ifndamp* -- the ftable that contains the damping factor of each mass. It should have the same size as the intended mass number.

*ileft* -- If *init* < 0, the position of the left hammer (*ileft* = 0 is hit at leftmost, *ileft* = 1 is hit at rightmost).

*iright* -- If *init* < 0, the position of the right hammer (*iright* = 0 is hit at leftmost, *iright* = 1 is hit at rightmost).

*idisp* -- If 0, no display of the masses is provided.

*id* -- If positive, the ID of the opcode. This will be used to point the scanning opcode to the proper waveform maker. If this value is negative, the absolute of this value is the wavetable on which to write the waveshape. That wavetable can be used later from an other opcode to generate sound. The initial contents of this table will be destroyed.

## Performance

*kmass* -- scales the masses

*kstif* -- scales the spring stiffness

*kcentr* -- scales the centering force

*kdampl* -- scales the damping

*kpos* -- position of an active hammer along the string (*kpos* = 0 is leftmost, *kpos* = 1 is rightmost). The shape of the hammer is determined by *init* and the power it pushes with is *kstrength*.

*kstrength* -- power that the active hammer uses

*ain* -- audio input that adds to the velocity of the masses. Amplitude should not be too great.

## Examples

For an example, see the documentation on *scans*.

# schedkwhen

`schedkwhen` — Adds a new score event generated by a k-rate trigger.

## Description

Adds a new score event generated by a k-rate trigger.

## Syntax

```
schedkwhen ktrigger, kmintim, kmaxnum,kinsnum,kwhen,kdur \
[, ip4] [, ip5] [...]
```

```
schedkwhen ktrigger, kmintim, kmaxnum, "insname", kwhen, kdur \
[, ip4] [, ip5] [...]
```

## Initialization

“*insname*” -- A string (in double-quotes) representing a named instrument.

*ip4, ip5, ...* -- Equivalent to p4, p5, etc., in a score *i statement*

## Performance

*ktrigger* -- triggers a new score event. If *ktrigger* = 0, no new event is triggered.

*kmintim* -- minimum time between generated events, in seconds. If *kmintim* <= 0, no time limit exists. If the *kinsnum* is negative (to turn off an instrument), this test is bypassed.

*kmaxnum* -- maximum number of simultaneous instances of instrument *kinsnum* allowed. If the number of existant instances of *kinsnum* is >= *kmaxnum*, no new event is generated. If *kmaxnum* is <= 0, it is not used to limit event generation. If the *kinsnum* is negative (to turn off an instrument), this test is bypassed.

*kinsnum* -- instrument number. Equivalent to p1 in a score *i statement*.

*kwhen* -- start time of the new event. Equivalent to p2 in a score *i statement*. Measured from the time of the triggering event. *kwhen* must be >= 0. If *kwhen* > 0, the instrument will not be initialized until the actual time when it should start performing.

*kdur* -- duration of event. Equivalent to p3 in a score *i statement*. If *kdur* = 0, the instrument will only do an initialization pass, with no performance. If *kdur* is negative, a held note is initiated. (See *ihold* and *i statement*.)

### Note

While waiting for events to be triggered by *schedkwhen*, the performance must be kept going, or Csound may quit if no score events are expected. To guarantee continued performance, an *f0 statement* may be used in the score.

### Note

Note that the *schedkwhen* opcode can't accept string p-fields. If you need to pass strings when instantiating an instrument, use the *scoreline* or *scoreline\_i* opcode.

## Examples

Here is an example of the *schedkwhen* opcode. It uses the file *schedkwhen.csd* [examples/schedkwhen.csd].

### Example 786. Example of the *schedkwhen* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# schedkwhennamed

`schedkwhennamed` — Similar to `schedkwhen` but uses a named instrument at init-time.

## Description

Similar to `schedkwhen` but uses a named instrument at init-time.

## Syntax

```
schedkwhennamed ktrigger, kmintim, kmaxnum, "name", kwhen, kdur \
[, ip4] [, ip5] [...]
```

## Initialization

*ip4, ip5, ...* -- Equivalent to p4, p5, etc., in a score *i statement*

## Performance

*ktrigger* -- triggers a new score event. If *ktrigger* is 0, no new event is triggered.

*kmintim* -- minimum time between generated events, in seconds. If *kmintim* is less than or equal to 0, no time limit exists.

*kmaxnum* -- maximum number of simultaneous instances of named instrument allowed. If the number of existant instances of the named instrument is greater than or equal to *kmaxnum*, no new event is generated. If *kmaxnum* is less than or equal to 0, it is not used to limit event generation.

*"name"* -- the named instrument's name.

*kwhen* -- start time of the new event. Equivalent to p2 in a score *i statement*. Measured from the time of the triggering event. *kwhen* must be greater than or equal to 0. If *kwhen* greater than 0, the instrument will not be initialized until the actual time when it should start performing.

*kdur* -- duration of event. Equivalent to p3 in a score *i statement*. If *kdur* is 0, the instrument will only do an initialization pass, with no performance. If *kdur* is negative, a held note is initiated. (See *ihold* and *i statement*.)

### Note

While waiting for events to be triggered by `schedkwhennamed`, the performance must be kept going, or Csound may quit if no score events are expected. To guarantee continued performance, an *f0 statement* may be used in the score.

### Note

Note that the `schedkwhennamed` opcode can't accept string p-fields. If you need to pass strings when instantiating an instrument, use the `scoreline` or `scoreline_i` opcode.

## Examples

Here is an example of the `schedkwhennamed` opcode. It uses the file `schedkwhennamed.csd` [examples/`schedkwhennamed.csd`].

### Example 787. Example of the `schedkwhennamed` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# schedule

`schedule` — Adds a new score event.

## Description

Adds a new score event.

## Syntax

```
schedule insnum, iwhen, idur [, ip4] [, ip5] [...]
```

```
schedule "insname", iwhen, idur [, ip4] [, ip5] [...]
```

## Initialization

*insnum* -- instrument number. Equivalent to p1 in a score *i statement*. *insnum* must be a number greater than the number of the calling instrument.

“*insname*” -- A string (in double-quotes) representing a named instrument.

*iwhen* -- start time of the new event. Equivalent to p2 in a score *i statement*. *iwhen* must be nonnegative. If *iwhen* is zero, *insnum* must be greater than or equal to the p1 of the current instrument.

*idur* -- duration of event. Equivalent to p3 in a score *i statement*.

*ip4, ip5, ...* -- Equivalent to p4, p5, etc., in a score *i statement*. The opcode also accepts strings as arguments for p4-pN.

## Performance

`schedule` adds a new score event. The arguments, including options, are the same as in a score. The *iwhen* time (p2) is measured from the time of this event.

If the duration is zero or negative the new event is of MIDI type, and inherits the release sub-event from the scheduling instruction.

## Examples

Here is an example of the `schedule` opcode. It uses the file `schedule.csd` [examples/schedule.csd].

### Example 788. Example of the schedule opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>

# schedwhen

`schedwhen` — Adds a new score event.

## Description

Adds a new score event.

## Syntax

```
schedwhen ktrigger,kinsnum,kwhen,kdur [, ip4] [, ip5] [...]  
schedwhen ktrigger, "insname", kwhen, kdur [, ip4] [, ip5] [...]
```

## Initialization

*ip4, ip5, ...* -- Equivalent to p4, p5, etc., in a score *i statement*.

## Performance

*kinsnum* -- instrument number. Equivalent to p1 in a score *i statement*.

“*insname*” -- A string (in double-quotes) representing a named instrument.

*ktrigger* -- trigger value for new event

*kwhen* -- start time of the new event. Equivalent to p2 in a score *i statement*.

*kdur* -- duration of event. Equivalent to p3 in a score *i statement*.

*schedwhen* adds a new score event. The event is only scheduled when the k-rate value *ktrigger* is first non-zero. The arguments, including options, are the same as in a score. The *kwhen* time (p2) is measured from the time of this event.

If the duration is zero or negative the new event is of MIDI type, and inherits the release sub-event from the scheduling instruction.

### Note

Note that the *schedwhen* opcode can't accept string p-fields. If you need to pass strings when instantiating an instrument, use the *scoreline* or *scoreline\_i* opcode.

## Examples

Here is an example of the *schedwhen* opcode. It uses the file *schedwhen.csd* [examples/schedwhen.csd].

### Example 789. Example of the *schedwhen* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command

line flags.

# scoreline

scoreline — Issues one or more score line events from an instrument.

## Description

Scoreline will issue one or more score events, if ktrig is 1 every k-period. It can handle strings in the same conditions as the standard score. Multi-line strings are accepted, using {{ }} to enclose the string.

## Syntax

```
scoreline Sin, ktrig
```

## Initialization

“*Sin*” -- a string (in double-quotes or enclosed by {{ }}) containing one or more score events.

## Performance

“*ktrig*” -- event trigger, 1 issues the score event, 0 bypasses it.

## Examples

Here is an example of the scoreline opcode. It uses the file *scoreline.csd* [examples/scoreline.csd].

### Example 790. Example of the scoreline opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac    ;;;realtime audio out
;-iadc   ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime output leave only the line below:
; -o scoreline.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1
ktrig metro 3
scoreline {{ i 2 0 3 "flute.aiff"
              i 2 1 3 "beats.wav"
            }}, ktrig
ktrig = 0
endin

instr 2
```

```
asig soundin p4
      outs asig*.3, asig*.3

endin
</CsInstruments>
<CsScore>

i1 0 2 ;play for 2 seconds, so the samples are played 6 times
e
</CsScore>
</CsoundSynthesizer>
```

You can use string opcodes like *sprintfk* to produce strings to be passed to *scoreline* like this:

```
Sfil = "/Volumes/Bla/file.aif"
String sprintfk {{i 2 0 %f "%s" %f %f %f %f}}, idur, Sfil, p5, p6, knorm, iskip
scoreline String, ktrig
```

# scoreline\_i

scoreline\_i — Issues one or more score line events from an instrument at i-time.

## Description

scoreline\_i will issue score events at i-time. It can handle strings in the same conditions as the standard score. Multi-line strings are accepted, using {{ }} to enclose the string.

## Syntax

```
scoreline_i Sin
```

## Initialization

“Sin” -- a string (in double-quotes or enclosed by {{ }}) containing one or more score events.

## Examples

Here is an example of the scoreline\_i opcode. It uses the file *scoreline\_i.csd* [examples/scoreline\_i.csd].

### Example 791. Example of the scoreline\_i opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# seed

`seed` — Sets the global seed value.

## Description

Sets the global seed value for all *x-class noise generators*, as well as other opcodes that use a random call, such as *grain*.

### Please Note

*rand*, *randh*, *randi*, *rnd(x)* and *birnd(x)* are not affected by *seed*.

## Syntax

```
seed ival
```

## Performance

Use of *seed* will provide predictable results from an orchestra using with random generators, when required from multiple performances.

When specifying a seed value, *ival* should be an integer between 0 and  $2^{32}$ . If *ival* = 0, the value of *ival* will be derived from the system clock.

## Examples

Here is an example of the *seed* opcode. It uses the file *seed.csd* [examples/seed.csd].

### Example 792. Example of the seed opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

```

# sekere

sekere — Semi-physical model of a sekere sound.

## Description

*sekere* is a semi-physical model of a sekere sound. It is one of the PhISEM percussion opcodes. PhISEM (Physically Informed Stochastic Event Modeling) is an algorithmic approach for simulating collisions of multiple independent sound producing objects.

## Syntax

```
ares sekere iamp, idettack [, inum] [, idamp] [, imaxshake]
```

## Initialization

*iamp* -- Amplitude of output. Note: As these instruments are stochastic, this is only a approximation.

*idettack* -- period of time over which all sound is stopped

*inum* (optional) -- The number of beads, teeth, bells, timbrels, etc. If zero, the default value is 64.

*idamp* (optional) -- the damping factor, as part of this equation:

$$\text{damping\_amount} = 0.998 + (\text{idamp} * 0.002)$$

The default *damping\_amount* is 0.999 which means that the default value of *idamp* is 0.5. The maximum *damping\_amount* is 1.0 (no damping). This means the maximum value for *idamp* is 1.0.

The recommended range for *idamp* is usually below 75% of the maximum value.

*imaxshake* (optional) -- amount of energy to add back into the system. The value should be in range 0 to 1.

## Examples

Here is an example of the sekere opcode. It uses the file *sekere.csd* [examples/sekere.csd].

### Example 793. Example of the sekere opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# semitone

semitone — Calculates a factor to raise/lower a frequency by a given amount of semitones.

## Description

Calculates a factor to raise/lower a frequency by a given amount of semitones.

## Syntax

```
semitone(x)
```

This function works at a-rate, i-rate, and k-rate.

## Initialization

*x* -- a value expressed in semitones.

## Performance

The value returned by the *semitone* function is a factor. You can multiply a frequency by this factor to raise/lower it by the given amount of semitones.

## Examples

Here is an example of the semitone opcode. It uses the file *semitone.csd* [examples/semitone.csd].

### Example 794. Example of the semitone opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## **sense**

sense — Same as the *sensekey* opcode.

## **Description**

Same as the *sensekey* opcode.

# sensekey

sensekey — Returns the ASCII code of a key that has been pressed.

## Description

Returns the ASCII code of a key that has been pressed, or -1 if no key has been pressed.

## Syntax

```
kres[, kkeydown] sensekey
```

## Performance

*kres* - returns the ASCII value of a key which is pressed or released.

*kkeydown* - returns 1 if the key was pressed, 0 if it was released or if there is no key event.

*kres* can be used to read keyboard events from stdin and returns the ASCII value of any key that is pressed or released, or it returns -1 when there is no keyboard activity. The value of *kkeydown* is 1 when a key was pressed, or 0 otherwise. This behavior is emulated by default, so a key release is generated immediately after every key press. To have full functionality, FLTK can be used to capture keyboard events. *FLpanel* can be used to capture keyboard events and send them to the *sensekey* opcode, by adding an additional optional argument. See *FLpanel* for more information.

### Note

This opcode can also be written as *sense*.

## Examples

Here is an example of the *sensekey* opcode. It uses the file *sensekey.csd* [examples/sensekey.csd].

### Example 795. Example of the sensekey opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>

# seqtime2

seqtime2 — Generates a trigger signal according to the values stored in a table.

## Description

Generates a trigger signal according to the values stored in a table.

## Syntax

```
ktrig_out seqtime2 ktrig_in, ktime_unit, kstart, kloop, kinitndx, kfn_times
```

## Performance

*ktrig\_out* -- output trigger signal

*ktime\_unit* -- unit of measure of time, related to seconds.

*ktrig\_in* -- input trigger signal.

*kstart* -- start index of looped section

*kloop* -- end index of looped section

*kinitndx* -- initial index

### Note

Although *kinitndx* is listed as k-rate, it is in fact accessed only at init-time. So if you are using a k-rate argument, it must be assigned with *init*.

*kfn\_times* -- number of table containing a sequence of times

This opcode handles timed-sequences of groups of values stored into a table.

*seqtime2* generates a trigger signal (a sequence of impulses, see also *trigger* opcode), according to the values stored in the *kfn\_times* table. This table should contain a series of delta-times (i.e. times between to adjacent events). The time units stored into table are expressed in seconds, but can be rescaled by means of *ktime\_unit* argument. The table can be filled with *GEN02* or by means of an external text-file containing numbers, with *GEN23*.

It is possible to start the sequence from a value different than the first, by assigning to *initndx* an index different than zero (which corresponds to the first value of the table). Normally the sequence is looped, and the start and end of loop can be adjusted by modifying *kstart* and *kloop* arguments. User must be sure that values of these arguments (as well as *initndx*) correspond to valid table numbers, otherwise Csound will crash (because no range-checking is implemented).

It is possible to disable loop (one-shot mode) by assigning the same value both to *kstart* and *kloop* arguments. In this case, the last read element will be the one corresponding to the value of such arguments. Table can be read backward by assigning a negative *kloop* value. It is possible to trigger two events almost at the same time (actually separated by a k-cycle) by giving a zero value to the corresponding delta-time. First element contained in the table should be zero, if the user intends to send a trigger impulse, it should come immediately after the orchestra instrument containing *seqtime2* opcode.

*seqtime2* is similar to *seqtime*, the difference is that when *ktrig\_in* contains a non-zero value, current index is reset to *kinitndx* value. *kinitndx* can be varied at performance time.

## Examples

Here is an example of the *seqtime2* opcode. It uses the file *seqtime2.csd* [examples/seqtime2.csd].

### Example 801. Example of the seqtime2 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# seqtime

seqtime — Generates a trigger signal according to the values stored in a table.

## Description

Generates a trigger signal according to the values stored in a table.

## Syntax

```
ktrig_out seqtime ktime_unit, kstart, kloop, kinitndx, kfn_times
```

## Performance

*ktrig\_out* -- output trigger signal

*ktime\_unit* -- unit of measure of time, related to seconds.

*kstart* -- start index of looped section

*kloop* -- end index of looped section

*kinitndx* -- initial index

### Note

Although *kinitndx* is listed as k-rate, it is in fact accessed only at init-time. So if you are using a k-rate argument, it must be assigned with *init*.

*kfn\_times* -- number of table containing a sequence of times

This opcode handles timed-sequences of groups of values stored into a table.

*seqtime* generates a trigger signal (a sequence of impulses, see also *trigger* opcode), according to the values stored in the *kfn\_times* table. This table should contain a series of delta-times (i.e. times between to adjacent events). The time units stored into table are expressed in seconds, but can be rescaled by means of *ktime\_unit* argument. The table can be filled with *GEN02* or by means of an external text-file containing numbers, with *GEN23*.

### Note

Note that the *kloop* index marks the loop boundary and is NOT included in the looped elements. If you want to loop the first four elements, you would set *kstart* to 0 and *kloop* to 4.

It is possible to start the sequence from a value different than the first, by assigning to *kinitndx* an index different than zero (which corresponds to the first value of the table). Normally the sequence is looped, and the start and end of loop can be adjusted by modifying *kstart* and *kloop* arguments. User must be sure that values of these arguments (as well as *kinitndx*) correspond to valid table numbers, otherwise Csound will crash (because no range-checking is implemented).

It is possible to disable loop (one-shot mode) by assigning the same value both to *kstart* and *kloop* argu-

ments. In this case, the last read element will be the one corresponding to the value of such arguments. Table can be read backward by assigning a negative *kloop* value. It is possible to trigger two events almost at the same time (actually separated by a k-cycle) by giving a zero value to the corresponding delta-time. First element contained in the table should be zero, if the user intends to send a trigger impulse, it should come immediately after the orchestra instrument containing *seqtime* opcode.

## Examples

Here is an example of the *seqtime* opcode. It uses the file *seqtime.csd* [examples/seqtime.csd].

# setctrl

setctrl — Configurable slider controls for realtime user input.

## Description

Configurable slider controls for realtime user input. Requires Winsound or TCL/Tk. *setctrl* sets a slider to a specific value, or sets a minimum or maximum range.

## Syntax

```
setctrl inum, ival, itype
```

## Initialization

Note that this opcode is not available on Windows due to the implementation of pipes on that system

*inum* -- number of the slider to set

*ival* -- value to be sent to the slider

*itype* -- type of value sent to the slider as follows:

- 1 -- set the current value. Initial value is 0.
- 2 -- set the minimum value. Default is 0.
- 3 -- set the maximum value. Default is 127.
- 4 -- set the label. (New in Csound version 4.09)

## Performance

Calling *setctrl* will create a new slider on the screen. There is no theoretical limit to the number of sliders. Windows and TCL/Tk use only integers for slider values, so the values may need rescaling. GUIs usually pass values at a fairly slow rate, so it may be advisable to pass the output of control through *port*.

## Examples

Here is an example of the *setctrl* opcode. It uses the file *setctrl.csd* [examples/setctrl.csd].

### Example 803. Example of the setctrl opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# setksmps

`setksmps` — Sets the local *ksmps* value in an instrument or user-defined opcode block

## Description

Sets the local *ksmps* value in an instrument or user-defined opcode block.

## Syntax

`setksmps iksmps`

## Initialization

*iksmps* -- sets the local *ksmps* value.

If *iksmps* is set to zero, the *ksmps* of the caller instrument or opcode is used (this is the default behavior).

### Note

The local *ksmps* is implemented by splitting up a control period into smaller sub-kperiods and setting up the instrument local *ksmps* to the new value. This also requires converting the rate of k-rate input and output arguments (input variables receive the same value in all sub-kperiods, while outputs are written only in the last one). It also means that you cannot use a local *ksmps* that is higher than the global *ksmps*.

### Warning about local *ksmps*

When the local *ksmps* is not the same as the orchestra level *ksmps* value (as specified in the orchestra header), global a-rate operations must be carefully coded to access the data in a vector according to the local *ksmps*. The audio rate bus channel opcodes (chnget/chnset) can be used freely, however, as they will do the necessary conversion between ksmp sizes.

Other opcodes that require some care include:

- any access to “ga” variables
- a-rate zak opcodes (*zar*, *zaw*, etc.)
- *tablera* and *tablewa* (these two opcodes may in fact work, but caution is needed)
- The *in* and *out* opcode family cannot be used in local-*ksmps* UDOs (these read from, and write to global a-rate buffers), but are safe in local-*ksmps* instruments

In general, the local *ksmps* should be used with care as it is an experimental feature. Though it works correctly in most cases.

The *setksmps* statement can be used to set the local *ksmps* value of the instrument or user-defined opcode block. It has one i-time parameter specifying the new *ksmps* value (which is left unchanged if zero is used). *setksmps* should be used before any other opcodes (but allowed after *xin* in UDOs), otherwise

unpredictable results may occur.

## Performance

The syntax of a user-defined opcode block is as follows:

```
opcode name, outtypes, intypes
xinarg1 [, xinarg2] [, xinarg3] ... [xinargN]  xin
[setksmps iksmps]
... the rest of the instrument's code.
xout xoutarg1 [, xoutarg2] [, xoutarg3] ... [xoutargN]
endop
```

The new opcode can then be used with the usual syntax:

```
[xinarg1] [, xinarg2] ... [xinargN] name [xoutarg1] [, xoutarg2] ... [xoutargN] [, iksmps]
```

## Examples

See the example for the *opcode* opcode.

## Setrow

`setrow` — Sets a given row of a 2-dimensional array from a vector.

## Description

Sets a given row of a 2-dimensional array. The output is an 2-d array with the contents of the requested row set to values of the input array (1-d; if 2-d the first row of the input array is used).

## Syntax

```
kout[] setrow kin[], krow
```

## Performance

*kout[]* -- output array containing the set row. It will be created if it does not exist.

*kin[]* -- input array.

*krow* -- row to be set.

## Examples

TODO.

# sfilist

`sfilist` — Prints a list of all instruments of a previously loaded SoundFont2 (SF2) file.

## Description

Prints a list of all instruments of a previously loaded SoundFont2 (SF2) sample file. These opcodes allow management the sample-structure of SF2 files. In order to understand the usage of these opcodes, the user must have some knowledge of the SF2 format, so a brief description of this format can be found in the *SoundFont2 File Format Appendix*.

## Syntax

```
sfilist ifilhandle
```

## Initialization

`ifilhandle` -- unique number generated by `sfload` opcode to be used as an identifier for a SF2 file. Several SF2 files can be loaded and activated at the same time.

## Performance

`sfilist` prints a list of all instruments of a previously loaded SF2 file to the console.

These opcodes only support the sample structure of SF2 files. The modulator structure of the SoundFont2 format is not supported in Csound. Any modulation or processing to the sample data is left to the Csound user, bypassing all restrictions forced by the SF2 standard.

## Examples

Here is an example of the `sfilist` opcode. It uses the file `sfilist.csd` [examples/sfilist.csd].

### Example 805. Example of the sfilist opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# sfinstr3

**sfinstr3** — Plays a SoundFont2 (SF2) sample instrument, generating a stereo sound with cubic interpolation.

## Description

Plays a SoundFont2 (SF2) sample instrument, generating a stereo sound with cubic interpolation. These opcodes allow management the sample-structure of SF2 files. In order to understand the usage of these opcodes, the user must have some knowledge of the SF2 format, so a brief description of this format can be found in the *SoundFont2 File Format Appendix*.

## Syntax

```
ar1, ar2 sfinstr3 ivel, inotenum, xamp, xfreq, instrnum, ifilhandle \
[, iflag] [, ioffset]
```

## Initialization

*ivel* -- velocity value

*inotenum* -- MIDI note number value

*instrnum* -- number of an instrument of a SF2 file.

*ofilhandle* -- unique number generated by *sload* opcode to be used as an identifier for a SF2 file. Several SF2 files can be loaded and activated at the same time.

*iflag* (optional) -- flag regarding the behavior of *xfreq* and *inotenum*

*ioffset* (optional) -- start playing at offset, in samples.

## Performance

*xamp* -- amplitude correction factor

*xfreq* -- frequency value or frequency multiplier, depending by *iflag*. When *iflag* = 0, *xfreq* is a multiplier of a the default frequency, assigned by SF2 preset to the *inotenum* value. When *iflag* = 1, *xfreq* is the absolute frequency of the output sound, in Hz. Default is 0.

When *iflag* = 0, *inotenum* sets the frequency of the output according to the MIDI note number used, and *xfreq* is used as a multiplier. When *iflag* = 1, the frequency of the output, is set directly by *xfreq*. This allows the user to use any kind of micro-tuning based scales. However, this method is designed to work correctly only with presets tuned to the default equal temperament. Attempts to use this method with a preset already having non-standard tunings, or with drum-kit-based presets, could give unexpected results.

Adjustment of the amplitude can be done by varying the *xamp* argument, which acts as a multiplier.

The *ioffset* parameter allows the sound to start from a sample different than the first one. The user should make sure that its value is within the length of the specific sound. Otherwise, Csound will probably crash.

*sfinstr3* is a cubic-interpolation version of *sfinstr*. Difference of sound-quality is noticeable specially in bass-frequency-transposed samples. In high-freq-transposed samples the difference is less noticeable, and I suggest to use linear-interpolation versions, because they are faster.

These opcodes only support the sample structure of SF2 files. The modulator structure of the SoundFont2 format is not supported in Csound. Any modulation or processing to the sample data is left to the Csound user, bypassing all restrictions forced by the SF2 standard.

## Examples

Here is an example of the *sfinstr3* opcode. It uses the file *sfinstr3.csd* [examples/sfinstr3.csd].

### Example 806. Example of the *sfinstr3* opcode.

# sfinstr

`sfinstr` — Plays a SoundFont2 (SF2) sample instrument, generating a stereo sound.

## Description

Plays a SoundFont2 (SF2) sample instrument, generating a stereo sound. These opcodes allow management the sample-structure of SF2 files. In order to understand the usage of these opcodes, the user must have some knowledge of the SF2 format, so a brief description of this format can be found in the *SoundFont2 File Format Appendix*.

## Syntax

```
ar1, ar2 sfinstr ivel, inotenum, xamp, xfreq, instrnum, ifilhandle \
[, iflag] [, ioffset]
```

## Initialization

*ivel* -- velocity value

*inotenum* -- MIDI note number value

*instrnum* -- number of an instrument of a SF2 file.

*ofilhandle* -- unique number generated by *sload* opcode to be used as an identifier for a SF2 file. Several SF2 files can be loaded and activated at the same time.

*iflag* (optional) -- flag regarding the behavior of *xfreq* and *inotenum*

*ioffset* (optional) -- start playing at offset, in samples.

## Performance

*xamp* -- amplitude correction factor

*xfreq* -- frequency value or frequency multiplier, depending by *iflag*. When *iflag* = 0, *xfreq* is a multiplier of a the default frequency, assigned by SF2 preset to the *inotenum* value. When *iflag* = 1, *xfreq* is the absolute frequency of the output sound, in Hz. Default is 0.

When *iflag* = 0, *inotenum* sets the frequency of the output according to the MIDI note number used, and *xfreq* is used as a multiplier. When *iflag* = 1, the frequency of the output, is set directly by *xfreq*. This allows the user to use any kind of micro-tuning based scales. However, this method is designed to work correctly only with presets tuned to the default equal temperament. Attempts to use this method with a preset already having non-standard tunings, or with drum-kit-based presets, could give unexpected results.

Adjustment of the amplitude can be done by varying the *xamp* argument, which acts as a multiplier.

The *ioffset* parameter allows the sound to start from a sample different than the first one. The user should make sure that its value is within the length of the specific sound. Otherwise, Csound will probably crash.

`sfinstr` plays an SF2 instrument instead of a preset (an SF2 instrument is the base of a preset layer). *in-*

*strnum* specifies the instrument number, and the user must be sure that the specified number belongs to an existing instrument of a determinate soundfont bank. Notice that both *xamp* and *xfreq* can operate at k-rate as well as a-rate, but both arguments must work at the same rate.

These opcodes only support the sample structure of SF2 files. The modulator structure of the SoundFont2 format is not supported in Csound. Any modulation or processing to the sample data is left to the Csound user, bypassing all restrictions forced by the SF2 standard.

## Examples

Here is an example of the *sfinstr* opcode. It uses the file *sfinstr.csd* [examples/sfinstr.csd].

### Example 808. Example of the *sfinstr* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# sfinstrm

`sfinstrm` — Plays a SoundFont2 (SF2) sample instrument, generating a mono sound.

## Description

Plays a SoundFont2 (SF2) sample instrument, generating a mono sound. These opcodes allow management the sample-structure of SF2 files. In order to understand the usage of these opcodes, the user must have some knowledge of the SF2 format, so a brief description of this format can be found in the *SoundFont2 File Format Appendix*.

## Syntax

```
ares sfinstrm ivel, inotenum, xamp, xfreq, instrnum, ifilhandle \
[, iflag] [, ioffset]
```

## Initialization

*ivel* -- velocity value

*inotenum* -- MIDI note number value

*instrnum* -- number of an instrument of a SF2 file.

*ofilhandle* -- unique number generated by *sload* opcode to be used as an identifier for a SF2 file. Several SF2 files can be loaded and activated at the same time.

*iflag* (optional) -- flag regarding the behavior of *xfreq* and *inotenum*

*ioffset* (optional) -- start playing at offset, in samples.

## Performance

*xamp* -- amplitude correction factor

*xfreq* -- frequency value or frequency multiplier, depending by *iflag*. When *iflag* = 0, *xfreq* is a multiplier of a the default frequency, assigned by SF2 preset to the *inotenum* value. When *iflag* = 1, *xfreq* is the absolute frequency of the output sound, in Hz. Default is 0.

When *iflag* = 0, *inotenum* sets the frequency of the output according to the MIDI note number used, and *xfreq* is used as a multiplier. When *iflag* = 1, the frequency of the output, is set directly by *xfreq*. This allows the user to use any kind of micro-tuning based scales. However, this method is designed to work correctly only with presets tuned to the default equal temperament. Attempts to use this method with a preset already having non-standard tunings, or with drum-kit-based presets, could give unexpected results.

Adjustment of the amplitude can be done by varying the *xamp* argument, which acts as a multiplier.

The *ioffset* parameter allows the sound to start from a sample different than the first one. The user should make sure that its value is within the length of the specific sound. Otherwise, Csound will probably crash.

*sfinstrm* is a mono version of *sfinstr*. This is the fastest opcode of the SF2 family.

These opcodes only support the sample structure of SF2 files. The modulator structure of the SoundFont2 format is not supported in Csound. Any modulation or processing to the sample data is left to the Csound user, bypassing all restrictions forced by the SF2 standard.

# **sfload**

*sfload* — Loads an entire SoundFont2 (SF2) sample file into memory.

## **Description**

Loads an entire SoundFont2 (SF2) sample file into memory. These opcodes allow management the sample-structure of SF2 files. In order to understand the usage of these opcodes, the user must have some knowledge of the SF2 format, so a brief description of this format can be found in the *SoundFont2 File Format Appendix*.

*sfload* should be placed in the header section of a Csound orchestra.

## **Syntax**

```
ir sfload "filename"
```

## **Initialization**

*ir* -- output to be used by other SF2 opcodes. For *sfload*, *ir* is *ifilhandle*.

“*filename*” -- name of the SF2 file, with its complete path. It must be a string typed within double-quotes with “/” to separate directories (this applies to DOS and Windows as well, where using a back-slash will generate an error), or an integer that has been the subject of a *strset* operation

## **Performance**

*sfload* loads an entire SF2 file into memory. It returns a file handle to be used by other opcodes. Several instances of *sfload* can placed in the header section of an orchestra, allowing use of more than one SF2 file in a single orchestra.

These opcodes only support the sample structure of SF2 files. The modulator structure of the SoundFont2 format is not supported in Csound. Any modulation or processing to the sample data is left to the Csound user, bypassing all restrictions forced by the SF2 standard.

It should be noted that before version 5.12 a maximum of 10 sound fonts could be loaded, a restriction since relaxed.

## **Examples**

Here is an example of the *sfload* opcode. It uses the file *sfload.csd* [examples/sfload.csd].

### **Example 809. Example of the sfload opcode.**

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# **sflooper**

**sflooper** — Plays a SoundFont2 (SF2) sample preset, generating a stereo sound, with user-defined time-varying crossfade looping.

## **Description**

Plays a SoundFont2 (SF2) sample preset, generating a stereo sound, similarly to *sfplay*. Unlike that opcode, though, it ignores the looping points set in the SF2 file and substitutes them for a user-defined crossfade loop. It is a cross between *sfplay* and *flooper2*.

## **Syntax**

```
ar1, ar2 sflooper ivel, inotenum, kamp, kpitch, ipreindex, kloopstart, kloopend, kcrossover \  
[, istart, imode, ifenv, iskip]
```

## **Initialization**

*ivel* -- velocity value

*inotenum* -- MIDI note number value

*ipreindex* -- preset index

*istart* -- playback start pos in seconds

*imode* -- loop modes: 0 forward, 1 backward, 2 back-and-forth [def: 0]

*ifenv* -- if non-zero, crossfade envelope shape table number. The default, 0, sets the crossfade to linear.

*iskip* -- if 1, the opcode initialisation is skipped, for tied notes, performance continues from the position in the loop where the previous note stopped. The default, 0, does not skip initialisation

## **Performance**

*kamp* -- amplitude scaling

*kpitch* -- pitch control (transposition ratio); negative values are not allowed.

*kloopstart* -- loop start point (secs). Note that although k-rate, loop parameters such as this are only updated once per loop cycle. If loop start is set beyond the end of the sample, no looping will result.

*kloopend* -- loop end point (secs), updated once per loop cycle.

*kcrossover* -- crossfade length (secs), updated once per loop cycle and limited to loop length.

*sflooper* plays a preset, generating a stereo sound.

These opcodes only support the sample structure of SF2 files. The modulator structure of the SoundFont2 format is not supported in Csound. Any modulation or processing to the sample data is left to the Csound user, bypassing all restrictions forced by the SF2 standard.

Note: The looping points are set on the root key of every sample that is part of the preset of the soundfont. For instance, a soundfont can have a single sample for the whole keyboard. In that case, sflooper

will work like flooper and flooper2, because as the sample is transposed, played back at different rates, the loop will get short or longer. If however the soundfont has a sample for each key, than there will be no transposition and the loop will stay the same length (unless you change kpitch).

## Examples

Here is an example of the sflooper opcode. It uses the file *sflooper.csd* [examples/sflooper.csd].

### Example 810. Example of the sflooper opcode.

# sfpassign

*sfpassign* — Assigns all presets of a SoundFont2 (SF2) sample file to a sequence of progressive index numbers.

## Description

Assigns all presets of a previously loaded SoundFont2 (SF2) sample file to a sequence of progressive index numbers. These opcodes allow management the sample-structure of SF2 files. In order to understand the usage of these opcodes, the user must have some knowledge of the SF2 format, so a brief description of this format can be found in the *SoundFont2 File Format Appendix*.

*sfpassign* should be placed in the header section of a Csound orchestra.

## Syntax

```
sfpassign istartindex, ifilhandle[, imsgs]
```

## Initialization

*istartindex* -- starting index preset by the user in bulk preset assignments.

*ofilhandle* -- unique number generated by *sfload* opcode to be used as an identifier for a SF2 file. Several SF2 files can be loaded and activated at the same time.

*imsgs* -- if non-zero messages are suppressed.

## Performance

*sfpassign* assigns all presets of a previously loaded SF2 file to a sequence of progressive index numbers, to be used later with the opcodes *sfplay* and *sfplaym*. *istartindex* specifies the starting index number. Any number of *sfpassign* instances can be placed in the header section of an orchestra, each one assigning presets belonging to different SF2 files. The user must take care that preset index numbers of different SF2 files do not overlap.

These opcodes only support the sample structure of SF2 files. The modulator structure of the SoundFont2 format is not supported in Csound. Any modulation or processing to the sample data is left to the Csound user, bypassing all restrictions forced by the SF2 standard.

## Examples

Here is an example of the *sfpassign* opcode. It uses the file *sfpassign.csd* [examples/sfpassign.csd].

### Example 811. Example of the sfpassign opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# **sfplay3**

**sfplay3** — Plays a SoundFont2 (SF2) sample preset, generating a stereo sound with cubic interpolation.

## **Description**

Plays a SoundFont2 (SF2) sample preset, generating a stereo sound with cubic interpolation. These op-codes allow management the sample-structure of SF2 files. In order to understand the usage of these op-codes, the user must have some knowledge of the SF2 format, so a brief description of this format can be found in the *SoundFont2 File Format Appendix*.

## **Syntax**

```
ar1, ar2 sfplay3 ivel, inotenum, xamp, xfreq, ipreindex [, iflag] [, ioffset] [, ienv]
```

## **Initialization**

*ivel* -- velocity value

*inotenum* -- MIDI note number value

*ipreindex* -- preset index

*iflag* (optional) -- flag regarding the behavior of *xfreq* and *inotenum*

*ioffset* (optional) -- start playing at offset, in samples.

*ienv* (optional) -- enables and determines amplitude envelope. 0 = no envelope, 1 = linear attack and decay, 2 = linear attack, exponential decay (see below). Default = 0.

## **Performance**

*xamp* -- amplitude correction factor

*xfreq* -- frequency value or frequency multiplier, depending by *iflag*. When *iflag* = 0, *xfreq* is a multiplier of a the default frequency, assigned by SF2 preset to the *inotenum* value. When *iflag* = 1, *xfreq* is the absolute frequency of the output sound, in Hz. Default is 0.

When *iflag* = 0, *inotenum* sets the frequency of the output according to the MIDI note number used, and *xfreq* is used as a multiplier. When *iflag* = 1, the frequency of the output, is set directly by *xfreq*. This allows the user to use any kind of micro-tuning based scales. However, this method is designed to work correctly only with presets tuned to the default equal temperament. Attempts to use this method with a preset already having non-standard tunings, or with drum-kit-based presets, could give unexpected results.

Adjustment of the amplitude can be done by varying the *xamp* argument, which acts as a multiplier.

Notice that both *xamp* and *xfreq* can use k-rate as well as a-rate signals. Both arguments must use variables of the same rate, or *sfplay3* will not work correctly. *ipreindex* must contain the number of a previously assigned preset, or Csound will crash.

The *ioffset* parameter allows the sound to start from a sample different than the first one. The user should make sure that its value is within the length of the specific sound. Otherwise, Csound will prob-

ably crash.

The *ienv* parameter enables and determines the type of amplitude envelope used. The default value is 0, or no envelope. If *ienv* is set to 1, the attack and decay portions are linear. If set to 2, the attack is linear and the decay is exponential. The release portion of the envelope has not yet been implemented.

*splay3* plays a preset, generating a stereo sound with cubic interpolation. *ivel* does not directly affect the amplitude of the output, but informs *splay3* about which sample should be chosen in multi-sample, velocity-split presets.

*splay3* is a cubic-interpolation version of *splay*. Difference of sound-quality is noticeable specially in bass-frequency-transposed samples. In high-freq-transposed samples the difference is less noticeable, and I suggest to use linear-interpolation versions, because they are faster.

These opcodes only support the sample structure of SF2 files. The modulator structure of the SoundFont2 format is not supported in Csound. Any modulation or processing to the sample data is left to the Csound user, bypassing all restrictions forced by the SF2 standard.

## Examples

Here is an example of the *splay3* opcode. It uses the file *splay3.csd* [examples/splay3.csd].

### Example 812. Example of the *splay3* opcode.

# **sfplay3m**

**sfplay3m** — Plays a SoundFont2 (SF2) sample preset, generating a mono sound with cubic interpolation.

## **Description**

Plays a SoundFont2 (SF2) sample preset, generating a mono sound with cubic interpolation. These op-codes allow management the sample-structure of SF2 files. In order to understand the usage of these op-codes, the user must have some knowledge of the SF2 format, so a brief description of this format can be found in the *SoundFont2 File Format Appendix*.

## **Syntax**

```
ares sfplay3m ivel, inotenum, xamp, xfreq, ipreindex [, iflag] [, ioffset] [, ienv]
```

## **Initialization**

*ivel* -- velocity value

*inotenum* -- MIDI note number value

*ipreindex* -- preset index

*iflag* (optional) -- flag regarding the behavior of *xfreq* and *inotenum*

*ioffset* (optional) -- start playing at offset, in samples.

*ienv* (optional) -- enables and determines amplitude envelope. 0 = no envelope, 1 = linear attack and decay, 2 = linear attack, exponential decay (see below). Default = 0.

## **Performance**

*xamp* -- amplitude correction factor

*xfreq* -- frequency value or frequency multiplier, depending by *iflag*. When *iflag* = 0, *xfreq* is a multiplier of a the default frequency, assigned by SF2 preset to the *inotenum* value. When *iflag* = 1, *xfreq* is the absolute frequency of the output sound, in Hz. Default is 0.

When *iflag* = 0, *inotenum* sets the frequency of the output according to the MIDI note number used, and *xfreq* is used as a multiplier. When *iflag* = 1, the frequency of the output, is set directly by *xfreq*. This allows the user to use any kind of micro-tuning based scales. However, this method is designed to work correctly only with presets tuned to the default equal temperament. Attempts to use this method with a preset already having non-standard tunings, or with drum-kit-based presets, could give unexpected results.

Adjustment of the amplitude can be done by varying the *xamp* argument, which acts as a multiplier.

Notice that both *xamp* and *xfreq* can use k-rate as well as a-rate signals. Both arguments must use variables of the same rate, or *sfplay3m* will not work correctly. *ipreindex* must contain the number of a previously assigned preset, or Csound will crash.

The *ioffset* parameter allows the sound to start from a sample different than the first one. The user

should make sure that its value is within the length of the specific sound. Otherwise, Csound will probably crash.

The *ienv* parameter enables and determines the type of amplitude envelope used. The default value is 0, or no envelope. If *ienv* is set to 1, the attack and decay portions are linear. If set to 2, the attack is linear and the decay is exponential. The release portion of the envelope has not yet been implemented.

*splay3m* is a mono version of *splay3*. It should be used with mono preset, or with the stereo presets in which stereo output is not required. It is faster than *splay3*.

*splay3m* is also a cubic-interpolation version of *splaym*. Difference of sound-quality is noticeable specially in bass-frequency-transposed samples. In high-freq-transposed samples the difference is less noticeable, and I suggest to use linear-interpolation versions, because they are faster.

These opcodes only support the sample structure of SF2 files. The modulator structure of the SoundFont2 format is not supported in Csound. Any modulation or processing to the sample data is left to the Csound user, bypassing all restrictions forced by the SF2 standard.

## Examples

Here is an example of the *splay3m* opcode. It uses the file *splay3m.csd* [examples/splay3m.csd].

### Example 813. Example of the *splay3m* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

New optional parameter *ienv* in version 5.09

# **sfplay**

**sfplay** — Plays a SoundFont2 (SF2) sample preset, generating a stereo sound.

## **Description**

Plays a SoundFont2 (SF2) sample preset, generating a stereo sound. These opcodes allow management the sample-structure of SF2 files. In order to understand the usage of these opcodes, the user must have some knowledge of the SF2 format, so a brief description of this format can be found in the *SoundFont2 File Format Appendix*.

## **Syntax**

```
ar1, ar2 sfplay ivel, inotenum, xamp, xfreq, ipreindex [, iflag] [, ioffset] [, ienv]
```

## **Initialization**

*ivel* -- velocity value

*inotenum* -- MIDI note number value

*ipreindex* -- preset index

*iflag* (optional) -- flag regarding the behavior of *xfreq* and *inotenum*

*ioffset* (optional) -- start playing at offset, in samples.

*ienv* (optional) -- enables and determines amplitude envelope. 0 = no envelope, 1 = linear attack and decay, 2 = linear attack, exponential decay (see below). Default = 0.

## **Performance**

*xamp* -- amplitude correction factor

*xfreq* -- frequency value or frequency multiplier, depending by *iflag*. When *iflag* = 0, *xfreq* is a multiplier of a the default frequency, assigned by SF2 preset to the *inotenum* value. When *iflag* = 1, *xfreq* is the absolute frequency of the output sound, in Hz. Default is 0.

When *iflag* = 0, *inotenum* sets the frequency of the output according to the MIDI note number used, and *xfreq* is used as a multiplier. When *iflag* = 1, the frequency of the output, is set directly by *xfreq*. This allows the user to use any kind of micro-tuning based scales. However, this method is designed to work correctly only with presets tuned to the default equal temperament. Attempts to use this method with a preset already having non-standard tunings, or with drum-kit-based presets, could give unexpected results.

Adjustment of the amplitude can be done by varying the *xamp* argument, which acts as a multiplier.

Notice that both *xamp* and *xfreq* can use k-rate as well as a-rate signals. Both arguments must use variables of the same rate, or *sfplay* will not work correctly. *ipreindex* must contain the number of a previously assigned preset, or Csound will crash.

The *ioffset* parameter allows the sound to start from a sample different than the first one. The user should make sure that its value is within the length of the specific sound. Otherwise, Csound will prob-

ably crash.

The *ienv* parameter enables and determines the type of amplitude envelope used. The default value is 0, or no envelope. If *ienv* is set to 1, the attack and decay portions are linear. If set to 2, the attack is linear and the decay is exponential. The release portion of the envelope has not yet been implemented.

*splay* plays a preset, generating a stereo sound. *ivel* does not directly affect the amplitude of the output, but informs *splay* about which sample should be chosen in multi-sample, velocity-split presets.

These opcodes only support the sample structure of SF2 files. The modulator structure of the SoundFont2 format is not supported in Csound. Any modulation or processing to the sample data is left to the Csound user, bypassing all restrictions forced by the SF2 standard.

# **sfplaym**

**sfplaym** — Plays a SoundFont2 (SF2) sample preset, generating a mono sound.

## **Description**

Plays a SoundFont2 (SF2) sample preset, generating a mono sound. These opcodes allow management the sample-structure of SF2 files. In order to understand the usage of these opcodes, the user must have some knowledge of the SF2 format, so a brief description of this format can be found in the *SoundFont2 File Format Appendix*.

## **Syntax**

```
ares sfplaym ivel, inotenum, xamp, xfreq, ipreindex [, iflag] [, ioffset] [, ienv]
```

## **Initialization**

*ivel* -- velocity value

*inotenum* -- MIDI note number value

*ipreindex* -- preset index

*iflag* (optional) -- flag regarding the behavior of *xfreq* and *inotenum*

*ioffset* (optional) -- start playing at offset, in samples.

*ienv* (optional) -- enables and determines amplitude envelope. 0 = no envelope, 1 = linear attack and decay, 2 = linear attack, exponential decay (see below). Default = 0.

## **Performance**

*xamp* -- amplitude correction factor

*xfreq* -- frequency value or frequency multiplier, depending by *iflag*. When *iflag* = 0, *xfreq* is a multiplier of a the default frequency, assigned by SF2 preset to the *inotenum* value. When *iflag* = 1, *xfreq* is the absolute frequency of the output sound, in Hz. Default is 0.

When *iflag* = 0, *inotenum* sets the frequency of the output according to the MIDI note number used, and *xfreq* is used as a multiplier. When *iflag* = 1, the frequency of the output, is set directly by *xfreq*. This allows the user to use any kind of micro-tuning based scales. However, this method is designed to work correctly only with presets tuned to the default equal temperament. Attempts to use this method with a preset already having non-standard tunings, or with drum-kit-based presets, could give unexpected results.

Adjustment of the amplitude can be done by varying the *xamp* argument, which acts as a multiplier.

Notice that both *xamp* and *xfreq* can use k-rate as well as a-rate signals. Both arguments must use variables of the same rate, or *sfplay* will not work correctly. *ipreindex* must contain the number of a previously assigned preset, or Csound will crash.

The *ioffset* parameter allows the sound to start from a sample different than the first one. The user should make sure that its value is within the length of the specific sound. Otherwise, Csound will prob-

ably crash.

The *ienv* parameter enables and determines the type of amplitude envelope used. The default value is 0, or no envelope. If *ienv* is set to 1, the attack and decay portions are linear. If set to 2, the attack is linear and the decay is exponential. The release portion of the envelope has not yet been implemented.

*splaym* is a mono version of *splay*. It should be used with mono preset, or with the stereo presets in which stereo output is not required. It is faster than *splay*.

These opcodes only support the sample structure of SF2 files. The modulator structure of the SoundFont2 format is not supported in Csound. Any modulation or processing to the sample data is left to the Csound user, bypassing all restrictions forced by the SF2 standard.

New in Csound Version 4.07

New optional parameter *ienv* in version 5.09

# sfplist

`sfplist` — Prints a list of all presets of a SoundFont2 (SF2) sample file.

## Description

Prints a list of all presets of a previously loaded SoundFont2 (SF2) sample file. These opcodes allow management the sample-structure of SF2 files. In order to understand the usage of these opcodes, the user must have some knowledge of the SF2 format, so a brief description of this format can be found in the *SoundFont2 File Format Appendix*.

## Syntax

```
sfplist ifilhandle
```

## Initialization

`ifilhandle` -- unique number generated by `sflload` opcode to be used as an identifier for a SF2 file. Several SF2 files can be loaded and activated at the same time.

## Performance

`sfplist` prints a list of all presets of a previously loaded SF2 file to the console.

These opcodes only support the sample structure of SF2 files. The modulator structure of the SoundFont2 format is not supported in Csound. Any modulation or processing to the sample data is left to the Csound user, bypassing all restrictions forced by the SF2 standard.

## Examples

Here is an example of the `sfplist` opcode. It uses the file `sfplist.csd` [examples/sfplist.csd].

### Example 815. Example of the `sfplist` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# **sfpreset**

`sfpreset` — Assigns an existing preset of a SoundFont2 (SF2) sample file to an index number.

## **Description**

Assigns an existing preset of a previously loaded SoundFont2 (SF2) sample file to an index number. These opcodes allow management the sample-structure of SF2 files. In order to understand the usage of these opcodes, the user must have some knowledge of the SF2 format, so a brief description of this format can be found in the *SoundFont2 File Format Appendix*.

*sfpreset* should be placed in the header section of a Csound orchestra.

## **Syntax**

```
ir sfpreset iprog, ibank, ifilhandle, ipreindex
```

## **Initialization**

*ir* -- output to be used by other SF2 opcodes. For *sfpreset*, *ir* is *ipreindex*.

*iprog* -- program number of a bank of presets in a SF2 file

*ibank* -- number of a specific bank of a SF2 file

*ifilhandle* -- unique number generated by *sfload* opcode to be used as an identifier for a SF2 file. Several SF2 files can be loaded and activated at the same time.

*ipreindex* -- preset index

## **Performance**

*sfpreset* assigns an existing preset of a previously loaded SF2 file to an index number, to be used later with the opcodes *sfplay* and *sfplaym*. The user must previously know the program and the bank numbers of the preset in order to fill the corresponding arguments. Any number of *sfpreset* instances can be placed in the header section of an orchestra, each one assigning a different preset belonging to the same (or different) SF2 file to different index numbers.

These opcodes only support the sample structure of SF2 files. The modulator structure of the SoundFont2 format is not supported in Csound. Any modulation or processing to the sample data is left to the Csound user, bypassing all restrictions forced by the SF2 standard.

## **Examples**

Here is an example of the *sfpreset* opcode. It uses the file *sfpreset.csd* [examples/sfpreset.csd].

### **Example 816. Example of the sfpreset opcode.**

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# shaker

`shaker` — Sounds like the shaking of a maraca or similar gourd instrument.

## Description

Audio output is a tone related to the shaking of a maraca or similar gourd instrument. The method is a physically inspired model developed from Perry Cook, but re-coded for Csound.

## Syntax

```
ares shaker kamp, kfreq, kbeans, kdamp, ktimes [, idecay]
```

## Initialization

`idecay` -- If present indicates for how long at the end of the note the shaker is to be damped. The default value is zero.

## Performance

A note is played on a maraca-like instrument, with the arguments as below.

`kamp` -- Amplitude of note.

`kfreq` -- Frequency of note played.

`kbeans` -- The number of beans in the gourd. A value of 8 seems suitable.

`kdamp` -- The damping value of the shaker. Values of 0.98 to 1 seems suitable, with 0.99 a reasonable default.

`ktimes` -- Number of times shaken.

### Note

The argument `knum` was redundant, so it was removed in version 3.49.

## Examples

Here is an example of the shaker opcode. It uses the file `shaker.csd` [examples/shaker.csd].

### Example 817. Example of the shaker opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# shiftin

`shiftin` — Shifts the contents of an audio variable into a 1-dimensional array.

## Description

This opcode can be used to push data from an audio variable into a 1-dimensional array. The array needs to be at least ksmps numbers long, but can be longer. Data is shifted in circularly, with the writing position moving by ksmps positions every k-cycle. When the array gets full, the writing position wraps around to the beginning of the array again (overwriting old positions). Together with the shiftout opcode, it can form a FIFO queue.

## Syntax

```
kout[] shiftin asig
```

## Performance

*kout[]* -- output array, needs to be at least ksmps numbers long.

*asig* -- input audio

## Examples

Here is an example of the shiftin opcode. It uses the file *shiftin.csd* [examples/shiftin.csd].

### Example 818. Example of the shiftin opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# shiftout

shiftout — Shifts the contents of a 1-dimensional array into an audio variable.

## Description

This opcode can be used to push data to an audio variable from a 1-dimensional array. The array needs to be at least ksmps numbers long, but can be longer. Data is shifted out circularly, with the writing position moving by ksmps positions every k-cycle. When the array gets emptied, the writing position wraps around to the beginning of the array again. Together with the shiftin opcode, it can form a FIFO queue.

## Syntax

```
asig shiftout kIn[], ioff
```

## Initialization

*ioff* -- initial read offset position (optional, defaults to 0).

## Performance

*kIn[]* -- input array, needs to be at least ksmps numbers long.

*asig* -- output audio

## Examples

Here is an example of the shiftout opcode. It uses the file *shiftout.csd* [examples/shiftout.csd].

### Example 819. Example of the shiftout opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# sin

sin — Performs a sine function.

## Description

Returns the sine of  $x$  ( $x$  in radians).

## Syntax

```
sin(x) (no rate restriction)
```

## Examples

Here is an example of the sin opcode. It uses the file *sin.csd* [examples/sin.csd].

### Example 821. Example of the sin opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac      ;;;realtime audio out
;-iadc      ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime output leave only the line below:
; -o sin.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1
    isin1    =      sin(0)                                ;sine of 0 is 0
    isin2    =      sin($M_PI_2)                          ;sine of pi/2 (1.5707...) is 1
    isin3    =      sin($M_PI)                            ;sine of pi (3.1415...) is 0
    isin4    =      sin($M_PI_2 * 3)                      ;sine of 3/2pi (4.7123...) is -1
    isin5    =      sin($M_PI * 2)                         ;sine of 2pi (6.2831...) is 0
    isin6    =      sin($M_PI * 4)                         ;sine of 4pi is also 0
    print    isin1, isin2, isin3, isin4, isin5, isin6
endin

instr 2 ;sin used in panning, after an example from Hans Mikelson

# sinsyn

sinsyn — Streaming partial track additive synthesis with cubic phase interpolation

## Description

The *sinsyn* opcode takes an input containing a TRACKS pv streaming signal (as generated, for instance by the *partials* opcode). It resynthesises the signal using linear amplitude and cubic phase interpolation to drive a bank of interpolating oscillators with amplitude scaling control. *sinsyn* attempts to preserve the phase of the partials in the original signal and in so doing it does not allow for pitch or timescale modifications of the signal.

## Syntax

```
asig sinsyn fin, kscal, kmaxtracks, ifn
```

## Performance

*asig* -- output audio rate signal

*fin* -- input pv stream in TRACKS format

*kscal* -- amplitude scaling

*kmaxtracks* -- max number of tracks in sinsynthesis. Limiting this will cause a non-linear filtering effect, by discarding newer and higher-frequency tracks (tracks are ordered by start time and ascending frequency, respectively)

*ifn* -- function table containing one cycle of a sinusoid (sine or cosine).

## Examples

Here is an example of the sinsyn opcode. It uses the file *sinsyn.csd* [examples/sinsyn.csd].

### Example 824. Example of the sinsyn opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>

# sleighbells

sleighbells — Semi-physical model of a sleighbell sound.

## Description

*sleighbells* is a semi-physical model of a sleighbell sound. It is one of the PhISEM percussion opcodes. PhISEM (Physically Informed Stochastic Event Modeling) is an algorithmic approach for simulating collisions of multiple independent sound producing objects.

## Syntax

```
ares sleighbells kamp, idettack [, inum] [, idamp] [, imaxshake] [, ifreq] \
[, ifreq1] [, ifreq2]
```

## Initialization

*idettack* -- period of time over which all sound is stopped

*inum* (optional) -- The number of beads, teeth, bells, timbrels, etc. If zero, the default value is 32.

*idamp* (optional) -- the damping factor, as part of this equation:

$$\text{damping\_amount} = 0.9994 + (\text{idamp} * 0.002)$$

The default *damping\_amount* is 0.9994 which means that the default value of *idamp* is 0. The maximum *damping\_amount* is 1.0 (no damping). This means the maximum value for *idamp* is 0.03.

The recommended range for *idamp* is usually below 75% of the maximum value.

*imaxshake* (optional, default=0) -- amount of energy to add back into the system. The value should be in range 0 to 1.

*ifreq* (optional) -- the main resonant frequency. The default value is 2500.

*ifreq1* (optional) -- the first resonant frequency. The default value is 5300.

*ifreq2* (optional) -- the second resonant frequency. The default value is 6500.

## Performance

*kamp* -- Amplitude of output. Note: As these instruments are stochastic, this is only an approximation.

## Examples

Here is an example of the sleighbells opcode. It uses the file *sleighbells.csd* [examples/sleighbells.csd].

### Example 825. Example of the sleighbells opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command

line flags.

# slider16

*slider16* — Creates a bank of 16 different MIDI control message numbers.

## Description

Creates a bank of 16 different MIDI control message numbers.

## Syntax

```
i1,...,i16 slider16 ichan, ictlnum1, imin1, imax1, init1, ifn1,..., \  
          ictlnum16, imin16, imax16, init16, ifn16
```

```
k1,...,k16 slider16 ichan, ictlnum1, imin1, imax1, init1, ifn1,..., \  
          ictlnum16, imin16, imax16, init16, ifn16
```

## Initialization

*i1 ... i16* -- output values

*ichan* -- MIDI channel (1-16)

*ictlnum1 ... ictlnum16* -- MIDI control number (0-127)

*imin1 ... imin16* -- minimum values for each controller

*imax1 ... imax16* -- maximum values for each controller

*init1 ... init16* -- initial value for each controller

*ifn1 ... ifn16* -- function table for conversion for each controller

## Performance

*k1 ... k16* -- output values

*slider16* is a bank of MIDI controllers, useful when using MIDI mixer such as Kawai MM-16 or others for changing whatever sound parameter in real-time. The raw MIDI control messages at the input port are converted to agree with *iminN* and *imaxN*, and an initial value can be set. Also, an optional non-interpolated function table with a custom translation curve is allowed, useful for enabling exponential response curves.

When no function table translation is required, set the *ifnN* value to 0, else set *ifnN* to a valid function table number. When table translation is enabled (i.e. setting *ifnN* value to a non-zero number referring to an already allocated function table), *initN* value should be set equal to *iminN* or *imaxN* value, else the initial output value will not be the same as specified in *initN* argument.

*slider16* allows a bank of 16 different MIDI control message numbers.

As the input and output arguments are many, you can split the line using '\' (backslash) character (new in 3.47 version) to improve the readability. Using these opcodes is considerably more efficient than using the separate ones (*ctrl7* and *tonek*) when more controllers are required.

In the i-rate version of *slider16*, there is not an initial value input argument, because the output is gotten

directly from current status of internal controller array of Csound.

# slider16f

*slider16f* — Creates a bank of 16 different MIDI control message numbers, filtered before output.

## Description

Creates a bank of 16 different MIDI control message numbers, filtered before output.

## Syntax

```
k1,...,k16 slider16f ichan, ictlnum1, imin1, imax1, init1, ifn1, \
icutoff1,..., ictlnum16, imin16, imax16, init16, ifn16, icutoff16
```

## Initialization

*ichan* -- MIDI channel (1-16)

*ictlnum1* ... *ictlnum16* -- MIDI control number (0-127)

*imin1* ... *imin16* -- minimum values for each controller

*imax1* ... *imax16* -- maximum values for each controller

*init1* ... *init16* -- initial value for each controller

*ifn1* ... *ifn16* -- function table for conversion for each controller

*icutoff1* ... *icutoff16* -- low-pass filter cutoff frequency for each controller

## Performance

*k1* ... *k16* -- output values

*slider16f* is a bank of MIDI controllers, useful when using MIDI mixer such as Kawai MM-16 or others for changing whatever sound parameter in real-time. The raw MIDI control messages at the input port are converted to agree with *iminN* and *imaxN*, and an initial value can be set. Also, an optional non-interpolated function table with a custom translation curve is allowed, useful for enabling exponential response curves.

When no function table translation is required, set the *ifnN* value to 0, else set *ifnN* to a valid function table number. When table translation is enabled (i.e. setting *ifnN* value to a non-zero number referring to an already allocated function table), *initN* value should be set equal to *iminN* or *imaxN* value, else the initial output value will not be the same as specified in *initN* argument.

*slider16f* allows a bank of 16 different MIDI control message numbers. It filters the signal before output. This eliminates discontinuities due to the low resolution of the MIDI (7 bit). The cutoff frequency can be set separately for each controller (suggested range: .1 to 5 Hz).

As the input and output arguments are many, you can split the line using '\' (backslash) character (new in 3.47 version) to improve the readability. Using these opcodes is considerably more efficient than using the separate ones (*ctrl7* and *tonek*) when more controllers are required.

## Warning

*slider16f* does not output the required initial value immediately, but only after some k-cycles because the filter slightly delays the output.

# slider16table

*slider16table* — Stores a bank of 16 different MIDI control messages to a table.

## Description

Stores a bank of 16 different MIDI control messages to a table.

## Syntax

```
kflag slider16table ichan, ioutTable, ioffset, ictlnum1, imin1, imax1, \
       init1, ifnl1, .... , ictlnum16, imin16, imax16, init16, ifn16
```

## Initialization

*ichan* -- MIDI channel (1-16)

*ioutTable* -- number of the table that will contain the output

*ioffset* -- output table offset. A zero means that the output of the first slider will affect the first table element. A 10 means that the output of the first slider will affect the 11th table element.

*ictlnum1* ... *ictlnum16* -- MIDI control number (0-127)

*imin1* ... *imin16* -- minimum values for each controller

*imax1* ... *imax16* -- maximum values for each controller

*init1* ... *init16* -- initial value for each controller

*ifn1* ... *ifn16* -- function table for conversion for each controller

## Performance

*kflag* -- a flag that informs if any control-change message in the bank has been received. In this case *kflag* is set to 1. Otherwise is set to zero.

*slider16table* is a bank of MIDI controllers, useful when using MIDI mixer such as Kawai MM-16 or others for changing whatever sound parameter in real-time. The raw MIDI control messages at the input port are converted to agree with *iminN* and *imaxN*, and an initial value can be set. Also, an optional non-interpolated function table with a custom translation curve is allowed, useful for enabling exponential response curves.

When no function table translation is required, set the *ifnN* value to 0, else set *ifnN* to a valid function table number. When table translation is enabled (i.e. setting *ifnN* value to a non-zero number referring to an already allocated function table), *initN* value should be set equal to *iminN* or *imaxN* value, else the initial output value will not be the same as specified in *initN* argument.

*slider16table* allows a bank of 16 different MIDI control message numbers.

As the input and output arguments are many, you can split the line using '\' (backslash) character (new in 3.47 version) to improve the readability. Using these opcodes is considerably more efficient than using the separate ones (*ctrl7* and *tonek*) when more controllers are required.

*slider16table* is very similar to *slider16* and *sliderN* family of opcodes (see their manual for more information). The actual difference is that the output is not stored to k-rate variables, but to a table, denoted by the *ioutTable* argument. It is possible to define a starting index in order to use the same table for more than one slider bank (or other purposes).

It is possible to use this opcode together with *FLslidBnk2Setk* and *FLslidBnk2*, so you can synchronize the position of the MIDI values to the position of the FLTK valuator widgets of *FLslidBnk2*. Notice that you have to specify the same min/max values as well the linear/exponential responses in both *sliderNtable(f)* and *FLslidBnk2*. The exception is when using table-indexed response instead of a lin/exp response. In this case, in order to achieve a useful result, the table-indexed response and actual min/max values must be set only in *FLslidBnk2*, whereas, in *sliderNtable(f)*, you have to set a linear response and a minimum of zero and a maximum of one in all sliders.

# slider16tablef

*slider16tablef* — Stores a bank of 16 different MIDI control messages to a table, filtered before output.

## Description

Stores a bank of 16 different MIDI control messages to a table, filtered before output.

## Syntax

```
kflag slider16tablef ichan, ioutTable, ioffset, ictlnum1, imin1, imax1, \
init1, ifn1, icutoff1, .... , ictlnum16, imin16, imax16, init16, ifn16, icutoff16
```

## Initialization

*ichan* -- MIDI channel (1-16)

*ioutTable* -- number of the table that will contain the output

*ioffset* -- output table offset. A zero means that the output of the first slider will affect the first table element. A 10 means that the output of the first slider will affect the 11th table element.

*ictlnum1* ... *ictlnum16* -- MIDI control number (0-127)

*imin1* ... *imin16* -- minimum values for each controller

*imax1* ... *imax16* -- maximum values for each controller

*init1* ... *init16* -- initial value for each controller

*ifn1* ... *ifn16* -- function table for conversion for each controller

*icutoff1* ... *icutoff16* -- low-pass filter cutoff frequency for each controller

## Performance

*kflag* -- a flag that informs if any control-change message in the bank has been received. In this case *kflag* is set to 1. Otherwise is set to zero.

*slider16tablef* is a bank of MIDI controllers, useful when using MIDI mixer such as Kawai MM-16 or others for changing whatever sound parameter in real-time. The raw MIDI control messages at the input port are converted to agree with *iminN* and *imaxN*, and an initial value can be set. Also, an optional non-interpolated function table with a custom translation curve is allowed, useful for enabling exponential response curves.

When no function table translation is required, set the *ifnN* value to 0, else set *ifnN* to a valid function table number. When table translation is enabled (i.e. setting *ifnN* value to a non-zero number referring to an already allocated function table), *initN* value should be set equal to *iminN* or *imaxN* value, else the initial output value will not be the same as specified in *initN* argument.

*slider16tablef* allows a bank of 16 different MIDI control message numbers. It filters the signal before output. This eliminates discontinuities due to the low resolution of the MIDI (7 bit). The cutoff frequency can be set separately for each controller (suggested range: .1 to 5 Hz).

As the input and output arguments are many, you can split the line using '\' (backslash) character (new in 3.47 version) to improve the readability. Using these opcodes is considerably more efficient than using the separate ones (*ctrl7* and *tonek*) when more controllers are required.

*slider16tablef* is very similar to *slider16f* and *sliderNf* family of opcodes (see their manual for more information). The actual difference is that the output is not stored to k-rate variables, but to a table, denoted by the *ioutTable* argument. It is possible to define a starting index in order to use the same table for more than one slider bank (or other purposes).

It is possible to use this opcode together with *FLslidBnk2Setk* and *FLslidBnk2*, so you can synchronize the position of the MIDI values to the position of the FLTK valuator widgets of *FLslidBnk2*. Notice that you have to specify the same min/max values as well the linear/exponential responses in both *sliderNtable(f)* and *FLslidBnk2*. The exception is when using table-indexed response instead of a lin/exp response. In this case, in order to achieve a useful result, the table-indexed response and actual min/max values must be set only in *FLslidBnk2*, whereas, in *sliderNtable(f)*, you have to set a linear response and a minimum of zero and a maximum of one in all sliders.

## Warning

*slider16tablef* does not output the required initial value immediately, but only after some k-cycles because the filter slightly delays the output.

# slider32

*slider32* — Creates a bank of 32 different MIDI control message numbers.

## Description

Creates a bank of 32 different MIDI control message numbers.

## Syntax

```
i1,...,i32 slider32 ichan, ictlnum1, imin1, imax1, init1, ifn1,..., \
ictlnum32, imin32, imax32, init32, ifn32
```

```
k1,...,k32 slider32 ichan, ictlnum1, imin1, imax1, init1, ifn1,..., \
ictlnum32, imin32, imax32, init32, ifn32
```

## Initialization

*i1 ... i32* -- output values

*ichan* -- MIDI channel (1-16)

*ictlnum1 ... ictlnum32* -- MIDI control number (0-127)

*imin1 ... imin32* -- minimum values for each controller

*imax1 ... imax32* -- maximum values for each controller

*init1 ... init32* -- initial value for each controller

*ifn1 ... ifn32* -- function table for conversion for each controller

## Performance

*k1 ... k32* -- output values

*slider32* is a bank of MIDI controllers, useful when using MIDI mixer such as Kawai MM-16 or others for changing whatever sound parameter in real-time. The raw MIDI control messages at the input port are converted to agree with *iminN* and *imaxN*, and an initial value can be set. Also, an optional non-interpolated function table with a custom translation curve is allowed, useful for enabling exponential response curves.

When no function table translation is required, set the *ifnN* value to 0, else set *ifnN* to a valid function table number. When table translation is enabled (i.e. setting *ifnN* value to a non-zero number referring to an already allocated function table), *initN* value should be set equal to *iminN* or *imaxN* value, else the initial output value will not be the same as specified in *initN* argument.

*slider32* allows a bank of 32 different MIDI control message numbers.

As the input and output arguments are many, you can split the line using '\' (backslash) character (new in 3.47 version) to improve the readability. Using these opcodes is considerably more efficient than using the separate ones (*ctrl7* and *tonek*) when more controllers are required.

In the i-rate version of *slider32*, there is not an initial value input argument, because the output is gotten

directly from current status of internal controller array of Csound.

# slider32table

*slider32table* — Stores a bank of 32 different MIDI control messages to a table.

## Description

Creates a bank of 32 different MIDI control messages to a table.

## Syntax

```
kflag slider32table ichan, ioutTable, ioffset, ictlnum1, imin1, \
       imax1, init1, ifnl, ..., ictlnum32, imin32, imax32, init32, ifn32
```

## Initialization

*ichan* -- MIDI channel (1-16)

*ioutTable* -- number of the table that will contain the output

*ioffset* -- output table offset. A zero means that the output of the first slider will affect the first table element. A 10 means that the output of the first slider will affect the 11th table element.

*ictlnum1* ... *ictlnum32* -- MIDI control number (0-127)

*imin1* ... *imin32* -- minimum values for each controller

*imax1* ... *imax32* -- maximum values for each controller

*init1* ... *init32* -- initial value for each controller

*ifn1* ... *ifn32* -- function table for conversion for each controller

## Performance

*kflag* -- a flag that informs if any control-change message in the bank has been received. In this case *kflag* is set to 1. Otherwise is set to zero.

*slider32table* is a bank of MIDI controllers, useful when using MIDI mixer such as Kawai MM-16 or others for changing whatever sound parameter in real-time. The raw MIDI control messages at the input port are converted to agree with *iminN* and *imaxN*, and an initial value can be set. Also, an optional non-interpolated function table with a custom translation curve is allowed, useful for enabling exponential response curves.

When no function table translation is required, set the *ifnN* value to 0, else set *ifnN* to a valid function table number. When table translation is enabled (i.e. setting *ifnN* value to a non-zero number referring to an already allocated function table), *initN* value should be set equal to *iminN* or *imaxN* value, else the initial output value will not be the same as specified in *initN* argument.

*slider32table* allows a bank of 32 different MIDI control message numbers.

As the input and output arguments are many, you can split the line using '\' (backslash) character (new in 3.47 version) to improve the readability. Using these opcodes is considerably more efficient than using the separate ones (*ctrl7* and *tonek*) when more controllers are required.

# slider8

*slider8* — Creates a bank of 8 different MIDI control message numbers.

## Description

Creates a bank of 8 different MIDI control message numbers.

## Syntax

```
i1,...,i8 slider8 ichan, ictlnum1, imin1, imax1, init1, ifn1,..., \
          ictlnum8, imin8, imax8, init8, ifn8

k1,...,k8 slider8 ichan, ictlnum1, imin1, imax1, init1, ifn1,..., \
          ictlnum8, imin8, imax8, init8, ifn8
```

## Initialization

*i1 ... i8* -- output values

*ichan* -- MIDI channel (1-16)

*ictlnum1 ... ictlnum8* -- MIDI control number (0-127)

*imin1 ... imin8* -- minimum values for each controller

*imax1 ... imax8* -- maximum values for each controller

*init1 ... init8* -- initial value for each controller

*ifn1 ... ifn8* -- function table for conversion for each controller

## Performance

*k1 ... k8* -- output values

*slider8* is a bank of MIDI controllers, useful when using MIDI mixer such as Kawai MM-16 or others for changing whatever sound parameter in real-time. The raw MIDI control messages at the input port are converted to agree with *iminN* and *imaxN*, and an initial value can be set. Also, an optional non-interpolated function table with a custom translation curve is allowed, useful for enabling exponential response curves.

When no function table translation is required, set the *ifnN* value to 0, else set *ifnN* to a valid function table number. When table translation is enabled (i.e. setting *ifnN* value to a non-zero number referring to an already allocated function table), *initN* value should be set equal to *iminN* or *imaxN* value, else the initial output value will not be the same as specified in *initN* argument.

*slider8* allows a bank of 8 different MIDI control message numbers.

As the input and output arguments are many, you can split the line using '\' (backslash) character (new in 3.47 version) to improve the readability. Using these opcodes is considerably more efficient than using the separate ones (*ctrl7* and *tonek*) when more controllers are required.

In the i-rate version of *slider8*, there is not an initial value input argument, because the output is gotten

directly from current status of internal controller array of Csound.

# slider8f

`slider8f` — Creates a bank of 8 different MIDI control message numbers, filtered before output.

## Description

Creates a bank of 8 different MIDI control message numbers, filtered before output.

## Syntax

```
k1,...,k8 slider8f ichan, ictlnum1, imin1, imax1, init1, ifn1, icutoff1, \
..., ictlnum8, imin8, imax8, init8, ifn8, icutoff8
```

## Initialization

*ichan* -- MIDI channel (1-16)

*ictlnum1* ... *ictlnum8* -- MIDI control number (0-127)

*imin1* ... *imin8* -- minimum values for each controller

*imax1* ... *imax8* -- maximum values for each controller

*init1* ... *init8* -- initial value for each controller

*ifn1* ... *ifn8* -- function table for conversion for each controller

*icutoff1* ... *icutoff8* -- low-pass filter cutoff frequency for each controller

## Performance

*k1* ... *k8* -- output values

*slider8f* is a bank of MIDI controllers, useful when using MIDI mixer such as Kawai MM-16 or others for changing whatever sound parameter in real-time. The raw MIDI control messages at the input port are converted to agree with *iminN* and *imaxN*, and an initial value can be set. Also, an optional non-interpolated function table with a custom translation curve is allowed, useful for enabling exponential response curves.

When no function table translation is required, set the *ifnN* value to 0, else set *ifnN* to a valid function table number. When table translation is enabled (i.e. setting *ifnN* value to a non-zero number referring to an already allocated function table), *initN* value should be set equal to *iminN* or *imaxN* value, else the initial output value will not be the same as specified in *initN* argument.

*slider8f* allows a bank of 8 different MIDI control message numbers. It filters the signal before output. This eliminates discontinuities due to the low resolution of the MIDI (7 bit). The cutoff frequency can be set separately for each controller (suggested range: .1 to 5 Hz).

As the input and output arguments are many, you can split the line using '\' (backslash) character (new in 3.47 version) to improve the readability. Using these opcodes is considerably more efficient than using the separate ones (*ctrl7* and *tonek*) when more controllers are required.

## Warning

*slider8f* opcodes do not output the required initial value immediately, but only after some k-cycles because the filter slightly delays the output.

# slider8table

*slider8table* — Stores a bank of 8 different MIDI control messages to a table.

## Description

Stores a bank of 8 different MIDI control messages to a table.

## Syntax

```
kflag slider8table ichan, ioutTable, ioffset, ictlnum1, imin1, imax1, \
       init1, ifn1,..., ictlnum8, imin8, imax8, init8, ifn8
```

## Initialization

*i1* ... *i8* -- output values

*ichan* -- MIDI channel (1-16)

*ioutTable* -- number of the table that will contain the output

*ioffset* -- output table offset. A zero means that the output of the first slider will affect the first table element. A 10 means that the output of the first slider will affect the 11th table element.

*ictlnum1* ... *ictlnum8* -- MIDI control number (0-127)

*imin1* ... *imin8* -- minimum values for each controller

*imax1* ... *imax8* -- maximum values for each controller

*init1* ... *init8* -- initial value for each controller

*ifn1* ... *ifn8* -- function table for conversion for each controller

## Performance

*kflag* -- a flag that informs if any control-change message in the bank has been received. In this case *kflag* is set to 1. Otherwise is set to zero.

*slider8table* handles a bank of MIDI controllers, useful when using MIDI mixer such as Kawai MM-16 or others for changing whatever sound parameter in real-time. The raw MIDI control messages at the input port are converted to agree with *iminN* and *imaxN*, and an initial value can be set. Also, an optional non-interpolated function table with a custom translation curve is allowed, useful for enabling exponential response curves.

When no function table translation is required, set the *ifnN* value to 0, else set *ifnN* to a valid function table number. When table translation is enabled (i.e. setting *ifnN* value to a non-zero number referring to an already allocated function table), *initN* value should be set equal to *iminN* or *imaxN* value, else the initial output value will not be the same as specified in *initN* argument.

*slider8table* allows a bank of 8 different MIDI control message numbers.

As the input and output arguments are many, you can split the line using '\' (backslash) character (new in 3.47 version) to improve the readability. Using these opcodes is considerably more efficient than using

the separate ones (*ctrl7* and *tonek*) when more controllers are required.

*slider8table* is very similar to *slider8* and *sliderN* family of opcodes (see their manual for more information). The actual difference is that the output is not stored to k-rate variables, but to a table, denoted by the *ioutTable* argument. It is possible to define a starting index in order to use the same table for more than one slider bank (or other purposes).

It is possible to use this opcode together with *FLslidBnk2Setk* and *FLslidBnk2*, so you can synchronize the position of the MIDI values to the position of the FLTK valuator widgets of *FLslidBnk2*. Notice that you have to specify the same min/max values as well the linear/exponential responses in both *sliderNtable(f)* and *FLslidBnk2*. The exception is when using table-indexed response instead of a lin/exp response. In this case, in order to achieve a useful result, the table-indexed response and actual min/max values must be set only in *FLslidBnk2*, whereas, in *sliderNtable(f)*, you have to set a linear response and a minimum of zero and a maximum of one in all sliders.

# sliderKawai

sliderKawai — Creates a bank of 16 different MIDI control message numbers from a KAWAI MM-16 midi mixer.

## Description

Creates a bank of 16 different MIDI control message numbers from a KAWAI MM-16 midi mixer.

## Syntax

```
k1, k2, ..., k16 sliderKawai imin1, imax1, init1, ifnl, \
imin2, imax2, init2, ifn2, ..., imin16, imax16, init16, ifn16
```

## Initialization

*imin1* ... *imin16* -- minimum values for each controller

*imax1* ... *imax16* -- maximum values for each controller

*init1* ... *init16* -- initial value for each controller

*ifn1* ... *ifn16* -- function table for conversion for each controller

## Performance

*k1* ... *k16* -- output values

The opcode *sliderKawai* is equivalent to *slider16*, but it has the controller and channel numbers (*ichan* and *ictlnum*) hard-coded to make for quick compatibility with the KAWAI MM-16 midi mixer. This device doesn't allow changing the midi message associated to each slider. It can only output on control 7 for each fader on a separate midi channel. This opcode is a quick way of assigning the mixer's 16 faders to k-rate variables in csound.

# sndloop

sndloop — A sound looper with pitch control.

## Description

This opcode records input audio and plays it back in a loop with user-defined duration and crossfade time. It also allows the pitch of the loop to be controlled, including reversed playback.

## Syntax

```
asig, krec sndloop ain, kpitch, ktrig, idur, ifad
```

## Initialization

*idur* -- loop duration in seconds

*ifad* -- crossfade duration in seconds

## Performance

*asig* -- output sig

*krec* -- 'rec on' signal, 1 when recording, 0 otherwise

*kpitch* -- pitch control (transposition ratio); negative values play the loop back in reverse

*ktrig* -- trigger signal: when 0, processing is bypassed. When switched on (*ktrig*  $\geq$  1), the opcode starts recording until the loop memory is full. It then plays the looped sound until it is switched off again (*ktrig* = 0). Another recording can start again with *ktrig*  $\geq$  1.

## Examples

Here is an example of the *sndloop* opcode. It uses the file *rndloop.csd* [examples/rndloop.csd].

### Example 827. Example of the *sndloop* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac      ;;;realtime audio out
;-iadc     ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime ouput leave only the line below:
;-o rndloop.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
0dbfs = 1
nchnls = 2
```

```
instr 1
    itrig = p4
    asig diskin2 "beats.wav", 1, 0, 1      ;get the signal in, loop it
    ktrig line 0, itrig, 1                  ;when to trigger signal = p4
    kpitch line 1.2, p3, .5                ;vary pitch of recorded signal
    aout,krec sndloop asig, kpitch, ktrig, .4, 0.05 ;rec starts at p4 sec, for .4 secs and 0.05 crossfade
    printk2 krec                         ; prints the recording signal
    outs     aout, aout

endin

</CsInstruments>
<CsScore>

i1 0 5 .5 ;trigger in seconds (=p4)
i1 + 5 .8
i1 + 10 1.2

e
</CsScore>
</CsoundSynthesizer>
```

The example above shows the basic operation of `sndloop`. Pitch can be controlled at the k-rate, recording is started as soon as the trigger value is  $\geq 1$ . Recording can be restarted by making the trigger 0 and then 1 again.

# **sndwarp**

**sndwarp** — Reads a mono sound sample from a table and applies time-stretching and/or pitch modification.

## **Description**

*sndwarp* reads sound samples from a table and applies time-stretching and/or pitch modification. Time and frequency modification are independent from one another. For example, a sound can be stretched in time while raising the pitch!

The window size and overlap arguments are important to the result and should be experimented with. In general they should be as small as possible. For example, start with *iwsizew=sr/10* and *ioverlap=15*. Try *irandw=iwsizew\*0.2*. If you can get away with less overlaps, the program will be faster. But too few may cause an audible flutter in the amplitude. The algorithm reacts differently depending upon the input sound and there are no fixed rules for the best use in all circumstances. But with proper tuning, excellent results can be achieved.

## **Syntax**

```
ares [, ac] sndwarp xamp, xtimewarp, xresample, ifn1, ibeg, iwsizew, \
irandw, ioverlap, ifn2, itimemode
```

## **Initialization**

*ifn1* -- the number of the table holding the sound samples which will be subjected to the *sndwarp* processing. *GEN01* is the appropriate function generator to use to store the sound samples from a pre-existing soundfile.

*ibeg* -- the time in seconds to begin reading in the table (or soundfile). When *itimemode* is non-zero, the value of *xtimewarp* is offset by *ibeg*.

*iwsizew* -- the window size in samples used in the time scaling algorithm.

*irandw* -- the bandwidth of a random number generator. The random numbers will be added to *iwsizew*.

*overlap* -- determines the density of overlapping windows.

*ifn2* -- a function used to shape the window. It is usually used to create a ramp of some kind from zero at the beginning and back down to zero at the end of each window. Try using a half sine (i.e.: f1 0 16384 9 .5 1 0) which works quite well. Other shapes can also be used.

## **Performance**

*ares* -- the single channel of output from the *sndwarp* unit generator. *sndwarp* assumes that the function table holding the sampled signal is a mono one. This simply means that *sndwarp* will index the table by single-sample frame increments. The user must be aware then that if a stereo signal is used with *sndwarp*, time and pitch will be altered accordingly.

*ac* (optional) -- a single-layer (no overlaps), unwindowed versions of the time and/or pitch altered signal. They are supplied in order to be able to balance the amplitude of the signal output, which typically contains many overlapping and windowed versions of the signal, with a clean version of the time-scaled and pitch-shifted signal. The *sndwarp* process can cause noticeable changes in amplitude, (up and

down), due to a time differential between the overlaps when time-shifting is being done. When used with a *balance* unit, *ac* can greatly enhance the quality of sound.

*xamp* -- the value by which to scale the amplitude (see note on the use of this when using *ac*).

*xtimewarp* -- determines how the input signal will be stretched or shrunk in time. There are two ways to use this argument depending upon the value given for *itimemode*. When the value of *itimemode* is 0, *xtimewarp* will scale the time of the sound. For example, a value of 2 will stretch the sound by 2 times. When *itimemode* is any non-zero value then *xtimewarp* is used as a time pointer in a similar way in which the time pointer works in *lspread* and *pvoc*. An example below illustrates this. In both cases, the pitch will *not* be altered by this process. Pitch shifting is done independently using *xresample*.

*xresample* -- the factor by which to change the pitch of the sound. For example, a value of 2 will produce a sound one octave higher than the original. The timing of the sound, however, will *not* be altered.

## Examples

### Examples

Here is an example of the *sndwarp* opcode. It uses the file *sndwarp.csd* [examples/sndwarp.csd].

#### Example 828. Example of the *sndwarp* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac ;;;realtime audio out
;-iadc ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime output leave only the line below:
;-o sndwarp.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
0dbfs = 1
nchnls = 2

instr 1

ktimewarp line 0, p3, 2.7 ;length of "fox.wav"
kresample init 1           ;do not change pitch
ibeg = 0                   ;start at beginning
iwsize = 4410               ;window size in samples with
irandw = 882                 ;bandwidth of a random number generator
itimemode = 1                ;ktimewarp is "time" pointer
ioverlap = p4

asig sndwarp .5, ktimewarp, kresample, 1, ibeg, iwsize, irandw, ioverlap, 2, itimemode
outs asig, asig

endin
</CsInstruments>
<CsScore>
f 1 0 131072 1 "fox.wav" 0 0 0 ; audio file
f 2 0 1024 9 0.5 1 0          ; half of a sine wave

i 1 0 7 2                    ;different overlaps
i 1 + 7 5
i 1 + 7 15
e

</CsScore>
</CsoundSynthesizer>
```

The below example shows a slowing down or stretching of the sound stored in the stored table (*ifn1*). Over the duration of the note, the stretching will grow from no change from the original to a sound which is ten times “slower” than the original. At the same time the overall pitch will move upward over the duration by an octave.

```
iwindfun = 1
isampfun = 2
ibeg = 0
iwindsize = 2000
iwindrand = 400
ioverlap = 10
awarp line 1, p3, 1
aresamp line 1, p3, 2
kenv line 1, p3, .1
asig sndwarp kenv, awarp, aresamp, isampfun, ibeg, iwindsize, iwindrand, ioverlap, iwindfun, 0
```

Now, here's an example using *xtimewarp* as a time pointer and using stereo:

```
itimemode = 1
atime line 0, p3, 10
ar1, ar2 sndwarpst kenv, atime, aresamp, sampfun, ibeg, iwindsize, iwindrand, ioverlap, \
           iwindfun, itimemode
```

In the above, *atime* advances the time pointer used in the *sndwarpst* from 0 to 10 over the duration of the note. If *p3* is 20 then the sound will be two times slower than the original. Of course you can use a more complex function than just a single straight line to control the time factor.

Now the same as above but using the *balance* function with the optional outputs:

```
asig,acmp sndwarp 1, awarp, aresamp, isampfun, ibeg, iwindsize, iwindrand, ioverlap, iwindfun, itimemode
abal balance asig, acmp

asig1,asig2,acmp1,acmp2 sndwarpst 1, atime, aresamp, sampfun, ibeg, iwindsize, iwindrand, ioverlap, \
                           iwindfun, itimemode
abal1 balance asig1, acmp1
abal2 balance asig2, acmp2
```

In the above two examples notice the use of the *balance* unit. The output of *balance* can then be scaled, enveloped, sent to an *out* or *outs*, and so on. Notice that the amplitude arguments to *sndwarp* and *sndwarpst* are “1” in these examples. By scaling the signal after the *sndwarp* process, *abal*, *abal1*, and *abal2* should contain signals that have nearly the same amplitude as the original input signal to the *sndwarp* process. This makes it much easier to predict the levels and avoid samples out of range or sample values that are too small.

## More Advice

Only use the stereo version when you really need to be processing a stereo file. It is somewhat slower than the mono version and if you use the *balance* function it is slower again. There is nothing wrong with using a mono *sndwarp* in a stereo orchestra and sending the result to one or both channels of the stereo output!

# **sndwarpst**

**sndwarpst** — Reads a stereo sound sample from a table and applies time-stretching and/or pitch modification.

## **Description**

*sndwarpst* reads stereo sound samples from a table and applies time-stretching and/or pitch modification. Time and frequency modification are independent from one another. For example, a sound can be stretched in time while raising the pitch!

The window size and overlap arguments are important to the result and should be experimented with. In general they should be as small as possible. For example, start with *iwsize*=sr/10 and *overlap*=15. Try *irandw*=*iwsize*\*.2. If you can get away with less overlaps, the program will be faster. But too few may cause an audible flutter in the amplitude. The algorithm reacts differently depending upon the input sound and there are no fixed rules for the best use in all circumstances. But with proper tuning, excellent results can be achieved.

## **Syntax**

```
ar1, ar2 [,ac1] [, ac2]  sndwarpst xamp, xtimewarp, xresample, ifn1, \
ibeg, iwsize, irandw, ioverlap, ifn2, itimemode
```

## **Initialization**

*ifn1* -- the number of the table holding the sound samples which will be subjected to the  *sndwarpst* processing. *GEN01* is the appropriate function generator to use to store the sound samples from a pre-existing soundfile.

*ibeg* -- the time in seconds to begin reading in the table (or soundfile). When *itimemode* is non-zero, the value of *xtimewarp* is offset by *ibeg*.

*iwsize* -- the window size in samples used in the time scaling algorithm.

*irandw* -- the bandwidth of a random number generator. The random numbers will be added to *iwsize*.

*overlap* -- determines the density of overlapping windows.

*ifn2* -- a function used to shape the window. It is usually used to create a ramp of some kind from zero at the beginning and back down to zero at the end of each window. Try using a half a sine (i.e.: f1 0 16384 9 .5 1 0) which works quite well. Other shapes can also be used.

## **Performance**

*ar1, ar2* -- *ar1* and *ar2* are the stereo (left and right) outputs from  *sndwarpst*.  *sndwarpst* assumes that the function table holding the sampled signal is a stereo one.  *sndwarpst* will index the table by a two-sample frame increment. The user must be aware then that if a mono signal is used with  *sndwarpst*, time and pitch will be altered accordingly.

*ac1, ac2* -- *ac1* and *ac2* are single-layer (no overlaps), unwindowed versions of the time and/or pitch altered signal. They are supplied in order to be able to balance the amplitude of the signal output, which typically contains many overlapping and windowed versions of the signal, with a clean version of the time-scaled and pitch-shifted signal. The  *sndwarpst* process can cause noticeable changes in amplitude,

(up and down), due to a time differential between the overlaps when time-shifting is being done. When used with a *balance* unit, *ac1* and *ac2* can greatly enhance the quality of sound. They are optional, but note that they must both be present in the syntax (use both or neither). An example of how to use this is given below.

*xamp* -- the value by which to scale the amplitude (see note on the use of this when using *ac1* and *ac2*).

*xtimewarp* -- determines how the input signal will be stretched or shrunk in time. There are two ways to use this argument depending upon the value given for *itimemode*. When the value of *itimemode* is 0, *xtimewarp* will scale the time of the sound. For example, a value of 2 will stretch the sound by 2 times. When *itimemode* is any non-zero value then *xtimewarp* is used as a time pointer in a similar way in which the time pointer works in *lspread* and *pvoc*. An example below illustrates this. In both cases, the pitch will *not* be altered by this process. Pitch shifting is done independently using *xresample*.

*xresample* -- the factor by which to change the pitch of the sound. For example, a value of 2 will produce a sound one octave higher than the original. The timing of the sound, however, will *not* be altered.

## Example

Here is an example of the *sndwarpst* opcode. It uses the file *sndwarpst.csd* [examples/sndwarpst.csd].

### Example 829. Example of the *sndwarpst* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>

</CsScore>
```

```
</CsoundSynthesizer>
```

## Other examples

The below example shows a slowing down or stretching of the sound stored in the stored table (*ifn1*). Over the duration of the note, the stretching will grow from no change from the original to a sound which is ten times “slower” than the original. At the same time the overall pitch will move upward over the duration by an octave.

```
iwindfun = 1
isampfun = 2
ibeg = 0
iwindsize = 2000
iwindrand = 400
ioverlap = 10
awarp    line      1, p3, 1
aresamp  line      1, p3, 2
kenv     line      1, p3, .1
asig     sndwarp kenv, awarp, aresamp, isampfun, ibeg, iwindsize, iwindrand, ioverlap, iwindfun, 0
```

Now, here's an example using *xtimewarp* as a time pointer and using stereo:

```
itimemode      =      1
atime          line      0, p3, 10
ar1, ar2      sndwarpst kenv, atime, aresamp, sampfun, ibeg, iwindsize, iwindrand, ioverlap, \
iwindfun, itimemode
```

In the above, *atime* advances the time pointer used in the *sndwarpst* from 0 to 10 over the duration of the note. If *p3* is 20 then the sound will be two times slower than the original. Of course you can use a more complex function than just a single straight line to control the time factor.

Now the same as above but using the *balance* function with the optional outputs:

```
asig,acmp    sndwarp 1, awarp, aresamp, isampfun, ibeg, iwindsize, iwindrand, ioverlap, iwindfun, itime
abal         balance asig, acmp
asig1,asig2,acmp1,acmp2 sndwarpst 1, atime, aresamp, sampfun, ibeg, iwindsize, iwindrand, ioverlap, \
iwindfun, itimemode
aball        balance asig1, acmp1
abal2        balance asig2, acmp2
```

In the above two examples notice the use of the *balance* unit. The output of *balance* can then be scaled, enveloped, sent to an *out* or *outs*, and so on. Notice that the amplitude arguments to *sndwarp* and *sndwarpst* are “1” in these examples. By scaling the signal after the *sndwarp* process, *abal*, *aball*, and *abal2* should contain signals that have nearly the same amplitude as the original input signal to the *sndwarp* process. This makes it much easier to predict the levels and avoid samples out of range or sample values that are too small.

## More Advice

Only use the stereo version when you really need to be processing a stereo file. It is somewhat slower than the mono version and if you use the *balance* function it is slower again. There is nothing wrong with using a mono *sndwarp* in a stereo orchestra and sending the result to one or both channels of the stereo output!

# sockrecv

**sockrecv** — Receives data from other processes using the low-level UDP or TCP protocols

## Description

Receives directly using the UDP (*sockrecv* and *sockrecvs*) or TCP (*strecv*) protocol onto a network. The data is not subject to any encoding or special routing. The *sockrecvs* opcode receives a stereo signal interleaved.

## Syntax

```
asig sockrecv iport, ilength  
  
asigl, asigr sockrecvs iport, ilength  
  
asig strecv Sipaddr, iport
```

## Initialization

*Sipaddr* -- a string that is the IP address of the sender in standard 4-octet dotted form.

*iport* -- the number of the port that is used for the communication.

*ilength* -- the length of the individual packets in UDP transmission. This number must be sufficiently small to fit a single MTU, which is set to the save value of 1456. In UDP transmissions the sender and receiver needs agree on this value

## Performance

*asig, asigl, asigr* -- audio data to be received.

## Example

The example shows a mono signal being received on port 7777 using UDP.

```
sr = 44100  
ksmps = 100  
nchnls = 1  
  
instr 1  
a1 sockrecv    7777, 200  
out      a1  
endin
```

# socksend

**socksend** — Sends data to other processes using the low-level UDP or TCP protocols

## Description

Transmits data directly using the UDP (*socksend* and *socksends*) or TCP (*stsend*) protocol onto a network. The data is not subject to any encoding or special routing. The *socksends* opcode send a stereo signal interleaved.

## Syntax

```
socksend asig, Sipaddr, iport, ilength  
  
socksend ksig, Sipaddr, iport, ilength  
  
socksends asigl, asigr, Sipaddr, iport,  
           ilength  
  
stsend asig, Sipaddr, iport
```

## Initialization

*Sipaddr* -- a string that is the IP address of the receiver in standard 4-octet dotted form.

*iport* -- the number of the port that is used for the communication.

*ilength* -- the length of the individual packets in UDP transmission. This number must be sufficiently small to fit a single MTU, which is set to the save value of 1456. In UDP transmissions the receiver needs to know this value

## Performance

*asig, ksig, asigl, asigr* -- data to be transmitted.

## Example

The example shows a simple sine wave being sent just once to a computer called "172.16.0.255", on port 7777 using UDP. Note that .255 is often used for broadcasting.

```
sr = 44100  
ksmps = 100  
nchnls = 1  
  
instr 1  
a1 oscil      20000,441,1  
    socksend    a1, "172.16.0.255",7777, 200  
endin
```

# soundin

soundin — Reads audio data from an external device or stream.

## Description

Reads audio data from an external device or stream. Up to 24 channels may be read before v5.14, extended to 40 in later versions.

## Syntax

```
ar1[, ar2[, ar3[, ... a24]]] soundin ifilcod [, iskptim] [, iformat] \
[, iskipinit] [, ibufsize]
```

## Initialization

*ifilcod* -- integer or character-string denoting the source soundfile name. An integer denotes the file `soundin.filcod`; a character-string (in double quotes, spaces permitted) gives the filename itself, optionally a full pathname. If not a full path, the named file is sought first in the current directory, then in that given by the environment variable `SSDIR` (if defined) then by `SFDIR`. See also *GEN01*.

*iskptim* (optional, default=0) -- time in seconds of input sound to be skipped. The default value is 0. In Csound 5.00 and later, this may be negative to add a delay instead of skipping time.

*iformat* (optional, default=0) -- specifies the audio data file format:

- 1 = 8-bit signed char (high-order 8 bits of a 16-bit integer)
- 2 = 8-bit A-law bytes
- 3 = 8-bit U-law bytes
- 4 = 16-bit short integers
- 5 = 32-bit long integers
- 6 = 32-bit floats
- 7 = 8-bit unsigned int (not available in Csound versions older than 5.00)
- 8 = 24-bit int (not available in Csound versions older than 5.00)
- 9 = 64-bit doubles (not available in Csound versions older than 5.00)

*iskipinit* -- switches off all initialisation if non zero (default=0). This was introduced in 4\_23f13 and csound5.

*ibufsize* -- buffer size in mono samples (not sample frames). Not available in Csound versions older than 5.00. The default buffer size is 2048.

If *iformat* = 0 it is taken from the soundfile header, and if no header from the Csound *-o* command-line flag. The default value is 0.

# Performance

*soundin* is functionally an audio generator that derives its signal from a pre-existing file. The number of channels read in is controlled by the number of result cells, *a1*, *a2*, etc., which must match that of the input file. A *soundin* opcode opens this file whenever the host instrument is initialized, then closes it again each time the instrument is turned off.

There can be any number of *soundin* opcodes within a single instrument or orchestra. Two or more of them can read simultaneously from the same external file.

## Note to Windows users

Windows users typically use back-slashes, “\”, when specifying the paths of their files. As an example, a Windows user might use the path “c:\music\samples\loop001.wav”. This is problematic because back-slashes are normally used to specify special characters.

To correctly specify this path in Csound, one may alternately:

- *Use forward slashes*: c:/music/samples/loop001.wav
- *Use back-slash special characters*, “\\”: c:\\music\\samples\\loop001.wav

# Examples

Here is an example of the *soundin* opcode. It uses the file *soundin.csd* [examples/soundin.csd], *fox.wav* [examples/fox.wav] and *kickroll.wav* [examples/kickroll.wav].

### Example 830. Example of the soundin opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# Space

**space** — Distributes an input signal among 4 channels using cartesian coordinates.

## Description

*space* takes an input signal and distributes it among 4 channels using Cartesian xy coordinates to calculate the balance of the outputs. The xy coordinates can be defined in a separate text file and accessed through a Function statement in the score using *Gen28*, or they can be specified using the optional *kx*, *ky* arguments. The advantages to the former are:

1. A graphic user interface can be used to draw and edit the trajectory through the Cartesian plane
2. The file format is in the form time1 X1 Y1 time2 X2 Y2 time3 X3 Y3 allowing the user to define a time-tagged trajectory

*space* then allows the user to specify a time pointer (much as is used for *pvoc*, *lspread* and some other units) to have detailed control over the final speed of movement.

## Syntax

```
a1, a2, a3, a4  space asig, ifn, ktime, kreverbssend, kx, ky
```

## Initialization

*ifn* -- number of the stored function created using *Gen28*. This function generator reads a text file which contains sets of three values representing the xy coordinates and a time-tag for when the signal should be placed at that location. The file should look like:

```
0    -1    1
1     1    1
2     4    4
2.1   -4   -4
3     10   -10
5    -40    0
```

If that file were named “move” then the *Gen28* call in the score would like:

```
f1 0 0 28 "move"
```

*Gen28* takes 0 as the size and automatically allocates memory. It creates values to 10 milliseconds of resolution. So in this case there will be 500 values created by interpolating X1 to X2 to X3 and so on, and Y1 to Y2 to Y3 and so on, over the appropriate number of values that are stored in the function table. In the above example, the sound will begin in the left front, over 1 second it will move to the right front, over another second it move further into the distance but still in the right front, then in just 1/10th of a second it moves to the left rear, a bit distant. Finally over the last .9 seconds the sound will move to

the right rear, moderately distant, and it comes to rest between the two left channels (due west!), quite distant. Since the values in the table are accessed through the use of a time-pointer in the *space* unit, the actual timing can be made to follow the file's timing exactly or it can be made to go faster or slower through the same trajectory. If you have access to the GUI that allows one to draw and edit the files, there is no need to create the text files manually. But as long as the file is ASCII and in the format shown above, it doesn't matter how it is made!

## Important

If *ifn* is 0, then *space* will take its values for the xy coordinates from *kx* and *ky*.

# Performance

The configuration of the xy coordinates in space places the signal in the following way:

- a1 is -1, 1
- a2 is 1, 1
- a3 is -1, -1
- a4 is 1, -1

This assumes a loudspeaker set up as a1 is left front, a2 is right front, a3 is left back, a4 is right back. Values greater than 1 will result in sounds being attenuated, as if in the distance. *space* considers the speakers to be at a distance of 1; smaller values of xy can be used, but *space* will not amplify the signal in this case. It will, however balance the signal so that it can sound as if it were within the 4 speaker space. x=0, y=1, will place the signal equally balanced between left and right front channels, x=y=0 will place the signal equally in all 4 channels, and so on. Although there must be 4 output signals from *space*, it can be used in a 2 channel orchestra. If the xy's are kept so that y>=1, it should work well to do panning and fixed localization in a stereo field.

*asig* -- input audio signal.

*ktime* -- index into the table containing the xy coordinates. If used like:

```
    ktime      line 0, 5, 5  
    a1, a2, a3, a4  space asig, 1, ktime, ...
```

with the file "move" described above, the speed of the signal's movement will be exactly as described in that file. However:

```
    ktime      line 0, 10, 5
```

the signal will move at half the speed specified. Or in the case of:

```
    ktime      line 5, 15, 0
```

the signal will move in the reverse direction as specified and 3 times slower! Finally:

      ktime      *line* 2, 10, 3

will cause the signal to move only from the place specified in line 3 of the text file to the place specified in line 5 of the text file, and it will take 10 seconds to do it.

*kreverbssend* -- the percentage of the direct signal that will be factored along with the distance as derived from the xy coordinates to calculate signal amounts that can be sent to reverb units such as *reverb*, or *reverb2*.

*kx, ky* -- when *ifn* is 0, *space* and *spdist* will use these values as the xy coordinates to localize the signal.

## Examples

Here is an example of the space opcode. It uses the file *space\_quad.csd* [examples/space\_quad.csd].

### Example 831. Example of the space opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

<CsScore>
f1 0 0 28 "move"

i1 0 5      ;same time as ktime
i 99 0 10 ;keep reverb active
e
</CsScore>
</CsoundSynthesizer>
```

In the above example, the signal, *asig*, is moved according to the data in Function #1 indexed by *ktime*. *space* sends the appropriate amount of the signal internally to *spsend*. The outputs of the *spsend* are added to global accumulators in a common Csound style and the global signals are used as inputs to the reverb units in a separate instrument.

*space* can be useful for quad and stereo panning as well as fixed placed of sounds anywhere between two loudspeakers. Below is an example of the fixed placement of sounds in a stereo field using xy values from the score instead of a function table. It uses the file *space\_stereo.csd* [examples/*space\_stereo.csd*].

New in Csound version 3.48

# spat3d

spat3d — Positions the input sound in a 3D space and allows moving the sound at k-rate.

## Description

This opcode positions the input sound in a 3D space, with optional simulation of room acoustics, in various output formats. *spat3d* allows moving the sound at k-rate (this movement is interpolated internally to eliminate "zipper noise" if sr not equal to kr).

## Syntax

```
aW, aX, aY, aZ spat3d ain, kX, kY, kZ, idist, ift, imode, imdel, iovr [, istor]
```

## Initialization

*idist* -- For modes 0 to 3, *idist* is the unit circle distance in meters. For mode 4, *idist* is the distance between microphones.

The following formulas describe amplitude and delay as a function of sound source distance from microphone(s):

$$\text{amplitude} = 1 / (0.1 + \text{distance})$$

$$\text{delay} = \text{distance} / 340 \text{ (in seconds)}$$

Distance can be calculated as:

$$\text{distance} = \sqrt{iX^2 + iY^2 + iZ^2}$$

In Mode 4, distance can be calculated as:

$$\begin{aligned}\text{distance from left mic} &= \sqrt{(iX + idist/2)^2 + iY^2 + iZ^2} \\ \text{distance from right mic} &= \sqrt{(iX - idist/2)^2 + iY^2 + iZ^2}\end{aligned}$$

With *spat3d* the distance between the sound source and any microphone should be at least  $(340 * 18) / \text{sr}$  meters. Shorter distances will work, but may produce artifacts in some cases. There is no such limitation for *spat3di* and *spat3dt*.

Sudden changes or discontinuities in sound source location can result in pops or clicks. Very fast movement may also degrade quality.

*ift* -- Function table storing room parameters (for free field spatialization, set it to zero or negative). Ta-

ble size is 54. The values in the table are:

| Room Parameter | Purpose   |
|----------------|---|
| 0              | Early reflection recursion depth (0 is the sound source, 1 is the first reflection etc.) for spat3d and spat3di. The number of echoes for four walls (front, back, right, left) is: $N = (2*R + 2) * R$ . If all six walls are enabled: $N = (((4*R + 6)*R + 8)*R) / 3$ |
| 1              | Late reflection recursion depth (used by spat3dt only). spat3dt skips early reflections and renders echoes up to this level. If early reflection depth is negative, spat3d and spat3di will output zero, while spat3dt will start rendering from the sound source.      |
| 2              | imdel for spat3d. Overrides opcode parameter if non-negative.   |
| 3              | irlen for spat3dt. Overrides opcode parameter if non-negative.  |
| 4              | idist value. Overrides opcode parameter if $\geq 0$ .   |
| 5              | Random seed (0 - 65535) -1 seeds from current time.   |
| 6 - 53         | wall parameters (w = 6: ceil, w = 14: floor, w = 22: front, w = 30: back, w = 38: right, w = 46: left)  |
| w + 0          | Enable reflections from this wall (0: no, 1: yes)   |
| w + 1          | Wall distance from listener (in meters)   |
| w + 2          | Randomization of wall distance (0 - 1) (in units of $1 / (\text{wall distance})$ )  |
| w + 3          | Reflection level (-1 - 1)   |
| w + 4          | Parametric equalizer frequency in Hz.   |
| w + 5          | Parametric equalizer level (1.0: no filtering)  |
| w + 6          | Parametric equalizer Q (0.7071: no resonance)   |
| w + 7          | Parametric equalizer mode (0: peak EQ, 1: low shelf, 2: high shelf)   |

*imode* -- Output mode

- 0: B format with W output only (mono)

aout = aW

- 1: B format with W and Y output (stereo)

aleft = aW + 0.7071\*aY  
 aright = aW - 0.7071\*aY

- 2: B format with W, X, and Y output (2D). This can be converted to UHJ:

```

aWre, aWim    hilbert aW
aXre, aXim    hilbert aX
aYre, aYim    hilbert aY
aWXr = 0.0928*aXre + 0.4699*aWre
aWXiYr = 0.2550*aXim - 0.1710*aWim + 0.3277*aYre
aleft = aWXr + aWXiYr
aright = aWXr - aWXiYr

```

- 3: B format with all outputs (3D)
- 4: Simulates a pair of microphones (stereo output)

```

aW  butterlp aW, ifreq ; recommended values for ifreq
aY  butterlp aY, ifreq ; are around 1000 Hz
aleft = aW + aX
aright = aY + aZ

```

Mode 0 is the cheapest to calculate, while mode 4 is the most expensive.

In Mode 4, The optional lowpass filters can change the frequency response depending on direction. For example, if the sound source is located left to the listener then the high frequencies are attenuated in the right channel and slightly increased in the left. This effect can be disabled by not using filters. You can also experiment with other filters (tone etc.) for better effect.

Note that mode 4 is most useful for listening with headphones, and is also more expensive to calculate than the B-format (0 to 3) modes. The *idist* parameter in this case sets the distance between left and right microphone; for headphones, values between 0.2 - 0.25 are recommended, although higher settings up to 0.4 may be used for wide stereo effects.

More information about B format can be found here: [http://www.york.ac.uk/inst/mustech/3d\\_audio/ambis2.htm](http://www.york.ac.uk/inst/mustech/3d_audio/ambis2.htm)

*imdel* -- Maximum delay time for spat3d in seconds. This has to be longer than the delay time of the latest reflection (depends on room dimensions, sound source distance, and recursion depth; using this formula gives a safe (although somewhat overestimated) value:

$$\text{imdel} = (R + 1) * \sqrt{W*W + H*H + D*D} / 340.0$$

where R is the recursion depth, W, H, and D are the width, height, and depth of the room, respectively).

*iovr* -- Oversample ratio for spat3d (1 to 8). Setting it higher improves quality at the expense of memory and CPU usage. The recommended value is 2.

*istor* (optional, default=0) -- Skip initialization if non-zero (default: 0).

## Performance

*aW, aX, aY, aZ* -- Output signals

|    | <b>mode 0</b> | <b>mode 1</b> | <b>mode 2</b> | <b>mode 3</b> | <b>mode 4</b>        |
|----|---------------|---------------|---------------|---------------|----------------------|
| aW | W out         | W out         | W out         | W out         | left chn / low freq. |
| aX | 0             | 0             | X out         | X out         | left chn / high frq. |
| aY | 0             | Y out         | Y out         | Y out         | right chn / low frq. |
| aZ | 0             | 0             | 0             | Z out         | right chn / high fr. |

*ain* -- Input signal

*kX, kY, kZ* -- Sound source coordinates (in meters)

If you encounter very slow performance (up to 100 times slower), it may be caused by denormals (this is also true of many other IIR opcodes, including *butterlp*, *pareq*, *hilbert*, and many others). Underflows can be avoided by:

- Using the *denorm* opcode on *ain* before *spat3d*.
- mixing low level DC or noise to the input signal, e.g.

atmp rnd31 1/1e24, 0, 0

aW, aX, aY, aZ spa3di ain + atmp, ...

or

aW, aX, aY, aZ spa3di ain + 1/1e24, ...

- reducing *irlen* in the case of *spat3dt* (which does not have an input signal). A value of about 0.005 is suitable for most uses, although it also depends on EQ settings. If the equalizer is not used, “irlen” can be set to 0.

## Examples

Here is a example of the *spat3d* opcode that outputs a stereo file. It uses the file *spat3d\_stereo.csd* [examples/spat3d\_stereo.csd].

### Example 833. Stereo example of the *spat3d* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# spat3di

spat3di — Positions the input sound in a 3D space with the sound source position set at i-time.

## Description

This opcode positions the input sound in a 3D space, with optional simulation of room acoustics, in various output formats. With *spat3di*, sound source position is set at i-time.

## Syntax

```
aW, aX, aY, aZ spat3di ain, ix, iy, iz, idist, ift, imode [, istor]
```

## Initialization

*iX* -- Sound source X coordinate in meters (positive: right, negative: left)

*iY* -- Sound source Y coordinate in meters (positive: front, negative: back)

*iZ* -- Sound source Z coordinate in meters (positive: up, negative: down)

*idist* -- For modes 0 to 3, *idist* is the unit circle distance in meters. For mode 4, *idist* is the distance between microphones.

The following formulas describe amplitude and delay as a function of sound source distance from microphone(s):

$$\text{amplitude} = 1 / (0.1 + \text{distance})$$

$$\text{delay} = \text{distance} / 340 \text{ (in seconds)}$$

Distance can be calculated as:

$$\text{distance} = \sqrt{iX^2 + iY^2 + iZ^2}$$

In Mode 4, distance can be calculated as:

$$\begin{aligned}\text{distance from left mic} &= \sqrt{(iX + idist/2)^2 + iY^2 + iZ^2} \\ \text{distance from right mic} &= \sqrt{(iX - idist/2)^2 + iY^2 + iZ^2}\end{aligned}$$

With *spat3d* the distance between the sound source and any microphone should be at least  $(340 * 18) / sr$  meters. Shorter distances will work, but may produce artifacts in some cases. There is no such limitation for *spat3di* and *spat3dt*.

Sudden changes or discontinuities in sound source location can result in pops or clicks. Very fast movement may also degrade quality.

*ift* -- Function table storing room parameters (for free field spatialization, set it to zero or negative). Table size is 54. The values in the table are:

| Room Parameter | Purpose   |
|----------------|---|
| 0              | Early reflection recursion depth (0 is the sound source, 1 is the first reflection etc.) for spat3d and spat3di. The number of echoes for four walls (front, back, right, left) is: $N = (2*R + 2) * R$ . If all six walls are enabled: $N = (((4*R + 6)*R + 8)*R) / 3$ |
| 1              | Late reflection recursion depth (used by spat3dt only). spat3dt skips early reflections and renders echoes up to this level. If early reflection depth is negative, spat3d and spat3di will output zero, while spat3dt will start rendering from the sound source.      |
| 2              | imdel for spat3d. Overrides opcode parameter if non-negative.   |
| 3              | irlen for spat3dt. Overrides opcode parameter if non-negative.  |
| 4              | idist value. Overrides opcode parameter if $\geq 0$ .   |
| 5              | Random seed (0 - 65535) -1 seeds from current time.   |
| 6 - 53         | wall parameters (w = 6: ceil, w = 14: floor, w = 22: front, w = 30: back, w = 38: right, w = 46: left)  |
| w + 0          | Enable reflections from this wall (0: no, 1: yes)   |
| w + 1          | Wall distance from listener (in meters)   |
| w + 2          | Randomization of wall distance (0 - 1) (in units of 1 / (wall distance))  |
| w + 3          | Reflection level (-1 - 1)   |
| w + 4          | Parametric equalizer frequency in Hz.   |
| w + 5          | Parametric equalizer level (1.0: no filtering)  |
| w + 6          | Parametric equalizer Q (0.7071: no resonance)   |
| w + 7          | Parametric equalizer mode (0: peak EQ, 1: low shelf, 2: high shelf)   |

*imode* -- Output mode

- 0: B format with W output only (mono)

aout = aW

- 1: B format with W and Y output (stereo)

```
aleft = aW + 0.7071*aY
aright = aW - 0.7071*aY
```

- 2: B format with W, X, and Y output (2D). This can be converted to UHJ:

```
aWre, aWim hilbert aW
aXre, aXim hilbert aX
aYre, aYim hilbert aY
aWXr = 0.0928*aXre + 0.4699*aWre
aWXiYr = 0.2550*aXim - 0.1710*aWim + 0.3277*aYre
aleft = aWXr + aWXiYr
aright = aWXr - aWXiYr
```

- 3: B format with all outputs (3D)
- 4: Simulates a pair of microphones (stereo output)

```
aW butterlp aW, ifreq ; recommended values for ifreq
aY butterlp aY, ifreq ; are around 1000 Hz
aleft = aW + aX
aright = aY + aZ
```

Mode 0 is the cheapest to calculate, while mode 4 is the most expensive.

In Mode 4, The optional lowpass filters can change the frequency response depending on direction. For example, if the sound source is located left to the listener then the high frequencies are attenuated in the right channel and slightly increased in the left. This effect can be disabled by not using filters. You can also experiment with other filters (tone etc.) for better effect.

Note that mode 4 is most useful for listening with headphones, and is also more expensive to calculate than the B-format (0 to 3) modes. The *idist* parameter in this case sets the distance between left and right microphone; for headphones, values between 0.2 - 0.25 are recommended, although higher settings up to 0.4 may be used for wide stereo effects.

More information about B format can be found here: [http://www.york.ac.uk/inst/mustech/3d\\_audio/ambis2.htm](http://www.york.ac.uk/inst/mustech/3d_audio/ambis2.htm)

*istor* (optional, default=0) -- Skip initialization if non-zero (default: 0).

## Performance

*ain* -- Input signal

*aW, aX, aY, aZ* -- Output signals

|           | <b>mode 0</b> | <b>mode 1</b> | <b>mode 2</b> | <b>mode 3</b> | <b>mode 4</b>         |
|-----------|---------------|---------------|---------------|---------------|-----------------------|
| <i>aW</i> | W out         | W out         | W out         | W out         | left chn / low freq.  |
| <i>aX</i> | 0             | 0             | X out         | X out         | left chn / high freq. |

|    | <b>mode 0</b> | <b>mode 1</b> | <b>mode 2</b> | <b>mode 3</b> | <b>mode 4</b>        |
|----|---------------|---------------|---------------|---------------|----------------------|
| aY | 0             | Y out         | Y out         | Y out         | right chn / low frq. |
| aZ | 0             | 0             | 0             | Z out         | right chn / high fr. |

If you encounter very slow performance (up to 100 times slower), it may be caused by denormals (this is also true of many other IIR opcodes, including *butterlp*, *pareq*, *hilbert*, and many others). Underflows can be avoided by:

- Using the *denorm* opcode on *ain* before *spat3di*.
- mixing low level DC or noise to the input signal, e.g.

atmp rnd31 1/1e24, 0, 0

aW, aX, aY, aZ spat3di ain + atmp, ...

or

aW, aX, aY, aZ spa3di ain + 1/1e24, ...

- reducing *irlen* in the case of *spat3dt* (which does not have an input signal). A value of about 0.005 is suitable for most uses, although it also depends on EQ settings. If the equalizer is not used, “irlen” can be set to 0.

# spat3dt

**spat3dt** — Can be used to render an impulse response for a 3D space at i-time.

## Description

This opcode positions the input sound in a 3D space, with optional simulation of room acoustics, in various output formats. *spat3dt* can be used to render the impulse response at i-time, storing output in a function table, suitable for convolution.

## Syntax

```
spat3dt ioutft, ix, iy, iz, idist, ift, imode, irlen [, iftnocl]
```

## Initialization

*ioutft* -- Output ftable number for *spat3dt*. W, X, Y, and Z outputs are written interleaved to this table. If the table is too short, output will be truncated.

*iX* -- Sound source X coordinate in meters (positive: right, negative: left)

*iY* -- Sound source Y coordinate in meters (positive: front, negative: back)

*iZ* -- Sound source Z coordinate in meters (positive: up, negative: down)

*idist* -- For modes 0 to 3, *idist* is the unit circle distance in meters. For mode 4, *idist* is the distance between microphones.

The following formulas describe amplitude and delay as a function of sound source distance from microphone(s):

$$\text{amplitude} = 1 / (0.1 + \text{distance})$$

$$\text{delay} = \text{distance} / 340 \text{ (in seconds)}$$

Distance can be calculated as:

$$\text{distance} = \sqrt{iX^2 + iY^2 + iZ^2}$$

In Mode 4, distance can be calculated as:

$$\begin{aligned}\text{distance from left mic} &= \sqrt{(iX + idist/2)^2 + iY^2 + iZ^2} \\ \text{distance from right mic} &= \sqrt{(iX - idist/2)^2 + iY^2 + iZ^2}\end{aligned}$$

With *spat3d* the distance between the sound source and any microphone should be at least  $(340 * 18) / \text{sr}$  meters. Shorter distances will work, but may produce artifacts in some cases. There is no such limitation for *spat3di* and *spat3dt*.

Sudden changes or discontinuities in sound source location can result in pops or clicks. Very fast movement may also degrade quality.

*ift* -- Function table storing room parameters (for free field spatialization, set it to zero or negative). Table size is 54. The values in the table are:

| Room Parameter | Purpose   |
|----------------|---|
| 0              | Early reflection recursion depth (0 is the sound source, 1 is the first reflection etc.) for <i>spat3d</i> and <i>spat3di</i> . The number of echoes for four walls (front, back, right, left) is: $N = (2*R + 2) * R$ . If all six walls are enabled: $N = (((4*R + 6)*R + 8)*R) / 3$                |
| 1              | Late reflection recursion depth (used by <i>spat3dt</i> only). <i>spat3dt</i> skips early reflections and renders echoes up to this level. If early reflection depth is negative, <i>spat3d</i> and <i>spat3di</i> will output zero, while <i>spat3dt</i> will start rendering from the sound source. |
| 2              | imdel for <i>spat3d</i> . Overrides opcode parameter if non-negative.   |
| 3              | irlen for <i>spat3dt</i> . Overrides opcode parameter if non-negative.  |
| 4              | idist value. Overrides opcode parameter if $\geq 0$ .   |
| 5              | Random seed (0 - 65535) -1 seeds from current time.   |
| 6 - 53         | wall parameters (w = 6: ceil, w = 14: floor, w = 22: front, w = 30: back, w = 38: right, w = 46: left)  |
| w + 0          | Enable reflections from this wall (0: no, 1: yes)   |
| w + 1          | Wall distance from listener (in meters)   |
| w + 2          | Randomization of wall distance (0 - 1) (in units of 1 / (wall distance))  |
| w + 3          | Reflection level (-1 - 1)   |
| w + 4          | Parametric equalizer frequency in Hz.   |
| w + 5          | Parametric equalizer level (1.0: no filtering)  |
| w + 6          | Parametric equalizer Q (0.7071: no resonance)   |
| w + 7          | Parametric equalizer mode (0: peak EQ, 1: low shelf, 2: high shelf)   |

*imode* -- Output mode

- 0: B format with W output only (mono)

aout = aW

- 1: B format with W and Y output (stereo)

```
aleft = aW + 0.7071*aY
aright = aW - 0.7071*aY
```

- 2: B format with W, X, and Y output (2D). This can be converted to UHJ:

```
aWre, aWim hilbert aW
aXre, aXim hilbert aX
aYre, aYim hilbert aY
aWXr = 0.0928*aXre + 0.4699*aWre
aWXiYr = 0.2550*aXim - 0.1710*aWim + 0.3277*aYre
aleft = aWXr + aWXiYr
aright = aWXr - aWXiYr
```

- 3: B format with all outputs (3D)
- 4: Simulates a pair of microphones (stereo output)

```
aW butterlp aW, ifreq ; recommended values for ifreq
aY butterlp aY, ifreq ; are around 1000 Hz
aleft = aW + aX
aright = aY + aZ
```

Mode 0 is the cheapest to calculate, while mode 4 is the most expensive.

In Mode 4, The optional lowpass filters can change the frequency response depending on direction. For example, if the sound source is located left to the listener then the high frequencies are attenuated in the right channel and slightly increased in the left. This effect can be disabled by not using filters. You can also experiment with other filters (tone etc.) for better effect.

Note that mode 4 is most useful for listening with headphones, and is also more expensive to calculate than the B-format (0 to 3) modes. The *idist* parameter in this case sets the distance between left and right microphone; for headphones, values between 0.2 - 0.25 are recommended, although higher settings up to 0.4 may be used for wide stereo effects.

More information about B format can be found here: [http://www.york.ac.uk/inst/mustech/3d\\_audio/ambis2.htm](http://www.york.ac.uk/inst/mustech/3d_audio/ambis2.htm)

*irlen* -- Impulse response length of echoes (in seconds). Depending on filter parameters, values around 0.005-0.01 are suitable for most uses (higher values result in more accurate output, but slower rendering)

*iftnocl* (optional, default=0) -- Do not clear output ftable (mix to existing data) if set to 1, clear table before writing if set to 0 (default: 0).

## Examples

Here is an example of the *spat3dt* opcode. It uses the file *spat3dt.csd* [examples/spat3dt.csd].

**Example 836. Example of the spat3dt opcode.**

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# spdist

spdist — Calculates distance values from xy coordinates.

## Description

*spdist* uses the same xy data as *space*, also either from a text file using *Gen28* or from x and y arguments given to the unit directly. The purpose of this unit is to make available the values for distance that are calculated from the xy coordinates.

In the case of *space*, the xy values are used to determine a distance which is used to attenuate the signal and prepare it for use in *spsend*. But it is also useful to have these values for distance available to scale the frequency of the signal before it is sent to the *space* unit.

## Syntax

```
k1 spdist ifn, ktime, kx, ky
```

## Initialization

*ifn* -- number of the stored function created using *Gen28*. This function generator reads a text file which contains sets of three values representing the xy coordinates and a time-tag for when the signal should be placed at that location. The file should look like:

```
0    -1    1  
1     1    1  
2     4    4  
2.1   -4   -4  
3     10   -10  
5    -40    0
```

If that file were named "move" then the *Gen28* call in the score would like:

```
f1 0 0 28 "move"
```

*Gen28* takes 0 as the size and automatically allocates memory. It creates values to 10 milliseconds of resolution. So in this case there will be 500 values created by interpolating X1 to X2 to X3 and so on, and Y1 to Y2 to Y3 and so on, over the appropriate number of values that are stored in the function table. In the above example, the sound will begin in the left front, over 1 second it will move to the right front, over another second it move further into the distance but still in the right front, then in just 1/10th of a second it moves to the left rear, a bit distant. Finally over the last .9 seconds the sound will move to the right rear, moderately distant, and it comes to rest between the two left channels (due west!), quite distant. Since the values in the table are accessed through the use of a time-pointer in the *space* unit, the actual timing can be made to follow the file's timing exactly or it can be made to go faster or slower through the same trajectory. If you have access to the GUI that allows one to draw and edit the files, there is no need to create the text files manually. But as long as the file is ASCII and in the format shown above, it doesn't matter how it is made!

IMPORTANT: If *ifn* is 0 then *spdist* will take its values for the xy coordinates from *kx* and *ky*.

## Performance

The configuration of the xy coordinates in space places the signal in the following way:

- a1 is -1, 1
- a2 is 1, 1
- a3 is -1, -1
- a4 is 1, -1

This assumes a loudspeaker set up as a1 is left front, a2 is right front, a3 is left back, a4 is right back. Values greater than 1 will result in sounds being attenuated, as if in the distance. *space* considers the speakers to be at a distance of 1; smaller values of xy can be used, but *space* will not amplify the signal in this case. It will, however balance the signal so that it can sound as if it were within the 4 speaker space. x=0, y=1, will place the signal equally balanced between left and right front channels, x=y=0 will place the signal equally in all 4 channels, and so on. Although there must be 4 output signals from *space*, it can be used in a 2 channel orchestra. If the xy's are kept so that Y>=1, it should work well to do panning and fixed localization in a stereo field.

*ktime* -- index into the table containing the xy coordinates. If used like:

```
ktime      line 0, 5, 5  
a1, a2, a3, a4  space asig, 1, ktime, ...
```

with the file "move" described above, the speed of the signal's movement will be exactly as described in that file. However:

```
ktime      line 0, 10, 5
```

the signal will move at half the speed specified. Or in the case of:

```
ktime      line 5, 15, 0
```

the signal will move in the reverse direction as specified and 3 times slower! Finally:

```
ktime      line 2, 10, 3
```

will cause the signal to move only from the place specified in line 3 of the text file to the place specified in line 5 of the text file, and it will take 10 seconds to do it.

*kx, ky* -- when *ifn* is 0, *space* and *spdist* will use these values as the XY coordinates to localize the signal.

## Examples

---

Here is an example of the spdist opcode. It uses the file *spdist.csd* [examples/spdist.csd].

### Example 837. Example of the spdist opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# specaddm

`specaddm` — Perform a weighted add of two input spectra.

## Description

Perform a weighted add of two input spectra.

## Syntax

```
wsig specaddm wsig1, wsig2 [, imul2]
```

## Initialization

*imul2* (optional, default=0) -- if non-zero, scale the *wsig2* magnitudes before adding. The default value is 0.

## Performance

*wsig1* -- the first input spectra.

*wsig2* -- the second input spectra.

Do a weighted add of two input spectra. For each channel of the two input spectra, the two magnitudes are combined and written to the output according to:

$$\text{magout} = \text{mag1in} + \text{mag2in} * \text{imul2}$$

The operation is performed whenever the input *wsig1* is sensed to be new. This unit will (at Initialization) verify the consistency of the two spectra (equal size, equal period, equal mag types).

## See Also

*specdiff*, *specfilt*, *spechist*, *specscal*

# specdiff

`specdiff` — Finds the positive difference values between consecutive spectral frames.

## Description

Finds the positive difference values between consecutive spectral frames.

## Syntax

```
wsig specdiff wsigin
```

## Performance

*wsig* -- the output spectrum.

*wsigin* -- the input spectra.

Finds the positive difference values between consecutive spectral frames. At each new frame of *wsigin*, each magnitude value is compared with its predecessor, and the positive changes written to the output spectrum. This unit is useful as an energy onset detector.

## Examples

```
wsig2      specdiff    wsig1          ; sense onsets
wsig3      specfilt     wsig2, 2       ; absorb slowly
specdisp   wsig2, 0.1    ; & display both spectra
specdisp   wsig3, 0.1
```

## See Also

*specaddm*, *specfilt*, *spechist*, *specscal*

# specdisp

`specdisp` — Displays the magnitude values of the spectrum.

## Description

Displays the magnitude values of the spectrum.

## Syntax

```
specdisp wsig, iprd [, iwtflg]
```

## Initialization

*iprd* -- the period, in seconds, of each new display.

*iwtflg* (optional, default=0) -- wait flag. If non-zero, hold each display until released by the user. The default value is 0 (no wait).

## Performance

*wsig* -- the input spectrum.

Displays the magnitude values of spectrum *wsig* every *iprd* seconds (rounded to some integral number of *wsig*'s originating *iprd*).

## Examples

```
ksum      specsum    wsig, 1          ; sum the spec bins, and ksmooth
      if ksum < 2000 kgoto zero       ; if sufficient amplitude
      specptrk wsig                 ; pitch-track the signal
      kgoto    contin
zero:
      koc      =      0              ; else output zero
contin:
```

## See Also

*specsum*

# specfilt

`specfilt` — Filters each channel of an input spectrum.

## Description

Filters each channel of an input spectrum.

## Syntax

```
wsig specfilt wsigin, ifhtim
```

## Initialization

*ifhtim* -- half-time constant.

## Performance

*wsigin* -- the input spectrum.

Filters each channel of an input spectrum. At each new frame of *wsigin*, each magnitude value is injected into a 1st-order lowpass recursive filter, whose half-time constant has been initially set by sampling the ftable *ifhtim* across the (logarithmic) frequency space of the input spectrum. This unit effectively applies a *persistence* factor to the data occurring in each spectral channel, and is useful for simulating the *energy integration* that occurs during auditory perception. It may also be used as a time-attenuated running *histogram* of the spectral distribution.

## Examples

```
wsig2    specdiff   wsig1      ; sense onsets
wsig3    specfilt    wsig2, 2    ; absorb slowly
specdisp wsig2, 0.1   ; & display both spectra
specdisp wsig3, 0.1
```

## See Also

*specaddm*, *specdiff*, *spechist*, *specscl*

# spechist

**spechist** — Accumulates the values of successive spectral frames.

## Description

Accumulates the values of successive spectral frames.

## Syntax

```
wsig spechist wsigin
```

## Performance

*wsigin* -- the input spectra.

Accumulates the values of successive spectral frames. At each new frame of *wsigin*, the accumulations-to-date in each magnitude track are written to the output spectrum. This unit thus provides a running *histogram* of spectral distribution.

## Examples

```
wsig2    specdiff   wsig1      ; sense onsets
wsig3    specfilt    wsig2, 2   ; absorb slowly
specdisp wsig2, 0.1   ; & display both spectra

# specptrk

specptrk — Estimates the pitch of the most prominent complex tone in the spectrum.

## Description

Estimate the pitch of the most prominent complex tone in the spectrum.

## Syntax

```
koct, kamp specptrk wsig, kvar, ilo, ihi, istr, idbthresh, inptls, \
    irolloff [, iodd] [, iconfs] [, interp] [, ifprd] [, iwtflg]
```

## Initialization

*ilo, ihi, istr* -- pitch range conditioners (low, high, and starting) expressed in decimal octave form.

*idbthresh* -- energy threshold (in decibels) for pitch tracking to occur. Once begun, tracking will be continuous until the energy falls below one half the threshold (6 dB down), whence the *koct* and *kamp* outputs will be zero until the full threshold is again surpassed. *idbthresh* is a guiding value. At initialization it is first converted to the *idbout* mode of the source spectrum (and the 6 dB down point becomes .5, .25, or 1/root 2 for modes 0, 2 and 3). The values are also further scaled to allow for the weighted partial summation used during correlation. The actual thresholding is done using the internal weighted and summed *kamp* value that is visible as the second output parameter.

*inptls, irolloff* -- number of harmonic partials used as a matching template in the spectrally-based pitch detection, and an amplitude rolloff for the set expressed as some fraction per octave (linear, so don't roll off to negative). Since the partials and rolloff fraction can affect the pitch following, some experimentation will be useful: try 4 or 5 partials with .6 rolloff as an initial setting; raise to 10 or 12 partials with rolloff .75 for complex timbres like the bassoon (weak fundamental). Computation time is dependent on the number of partials sought. The maximum number is 16.

*iodd* (optional) -- if non-zero, employ only odd partials in the above set (e.g. *inptls* of 4 would employ partials 1,3,5,7). This improves the tracking of some instruments like the clarinet. The default value is 0 (employ all partials).

*iconfs* (optional) -- number of confirmations required for the pitch tracker to jump an octave, pro-rated for fractions of an octave (i.e. the value 12 implies a semitone change needs 1 confirmation (two hits) at the *spectrum* generating *iprd*). This parameter limits spurious pitch analyses such as octave errors. A value of 0 means no confirmations required; the default value is 10.

*interp* (optional) -- if non-zero, interpolate each output signal (*koct, kamp*) between incoming *wsig* frames. The default value is 0 (repeat the signal values between frames).

*ifprd* (optional) -- if non-zero, display the internally computed spectrum of candidate fundamentals. The default value is 0 (no display).

*iwtflg* (optional) -- wait flag. If non-zero, hold each display until released by the user. The default value is 0 (no wait).

## Performance

At note initialization this unit creates a template of *inptls* harmonically related partials (odd partials, if

(*iodd* non-zero) with amplitude rolloff to the fraction *irrolloff* per octave. At each new frame of *wsig*, the spectrum is cross-correlated with this template to provide an internal spectrum of candidate fundamentals (optionally displayed). A likely pitch/amp pair (*koct*, *kamp*, in decimal octave and summed *idbout* form) is then estimated. *koct* varies from the previous *koct* by no more than plus or minus *kvar* decimal octave units. It is also guaranteed to lie within the hard limit range *ilo* -- *ghi* (decimal octave low and high pitch). *kvar* can be dynamic, e.g. onset amp dependent. Pitch resolution uses the originating *spectrum ifrqs* bins/octave, with further parabolic interpolation between adjacent bins. Settings of root magnitude, *ifrqs* = 24, *iq* = 15 should capture all the inflections of interest. Between frames, the output is either repeated or interpolated at the k-rate. (See *spectrum*.)

## Examples

```
a1, a2    ins          ; read a stereo clarinet input
krms      rms          ; find a monaural rms value
kvar      =             ; & use to gate the pitch variance
wsig      spectrum     ; get a 7-oct spectrum, 24 bits
                  specdisp   ; display this and now estimate
koct, ka   spectrk     ; the pitch and amp
aosc      oscil        ; & generate \ new tone with track
koct      =             ; replace non pitch with low C
                  display    ; & display the pitch track
                  display    ; plus the summed root mag
outs      outs         ; output 1 original and 1 new
```

# specscal

`specscal` — Scales an input spectral datablock with spectral envelopes.

## Description

Scales an input spectral datablock with spectral envelopes.

## Syntax

```
wsig specscal wsigin, ifscale, ifthresh
```

## Initialization

*ifscale* -- scale function table. A function table containing values by which a value's magnitude is rescaled.

*ifthresh* -- threshold function table. If *ifthresh* is non-zero, each magnitude is reduced by its corresponding table-value (to not less than zero)

## Performance

*wsig* -- the output spectrum

*wsigin* -- the input spectra

Scales an input spectral datablock with spectral envelopes. Function tables *ifthresh* and *ifscale* are initially sampled across the (logarithmic) frequency space of the input spectrum; then each time a new input spectrum is sensed the sampled values are used to scale each of its magnitude channels as follows: if *ifthresh* is non-zero, each magnitude is reduced by its corresponding table-value (to not less than zero); then each magnitude is rescaled by the corresponding *ifscale* value, and the resulting spectrum written to *wsig*.

## Examples

```
wsig2    specdiff   wsig1      ; sense onsets
wsig3    specfilt    wsig2, 2    ; absorb slowly
specdisp wsig2, 0.1   ; & display both spectra
specdisp wsig3, 0.1
```

## See Also

*specaddm*, *specdiff*, *specfilt*, *spechist*

# specsum

`specsum` — Sums the magnitudes across all channels of the spectrum.

## Description

Sums the magnitudes across all channels of the spectrum.

## Syntax

```
ksum specsum wsig [, interp]
```

## Initialization

*interp* (optional, default-0) -- if non-zero, interpolate the output signal (*koct* or *ksum*). The default value is 0 (repeat the signal value between changes).

## Performance

*ksum* -- the output signal.

*wsig* -- the input spectrum.

Sums the magnitudes across all channels of the spectrum. At each new frame of *wsig*, the magnitudes are summed and released as a scalar *ksum* signal. Between frames, the output is either repeated or interpolated at the k-rate. This unit produces a k-signal summation of the magnitudes present in the spectral data, and is thereby a running measure of its moment-to-moment overall strength.

## Examples

```
ksum      specsum   wsig, 1           ; sum the spec bins, and ksmooth
      if ksum < 2000 kgoto zero        ; if sufficient amplitude
      specptrk wsig                  ; pitch-track the signal
      kgoto    contin
zero:
koct      =      0                   ; else output zero
contin:
```

## See Also

*specdisp*

# Spectrum

spectrum — Generate a constant-Q, exponentially-spaced DFT.

## Description

Generate a constant-Q, exponentially-spaced DFT across all octaves of a multiply-downsampled control or audio input signal.

## Syntax

```
wsig spectrum xsig, iprd, iocts, ifrqa [, iq] [, ihann] [, idbout] \
[, idsprd] [, idsinrs]
```

## Initialization

*ihann* (optional) -- apply a Hamming or Hanning window to the input. The default is 0 (Hamming window)

*idbout* (optional) -- coded conversion of the DFT output:

- 0 = magnitude
- 1 = dB
- 2 = mag squared
- 3 = root magnitude

The default value is 0 (magnitude).

*idisprd* (optional) -- if non-zero, display the composite downsampling buffer every *idisprd* seconds. The default value is 0 (no display).

*idsines* (optional) -- if non-zero, display the Hamming or Hanning windowed sinusoids used in DFT filtering. The default value is 0 (no sinusoid display).

## Performance

This unit first puts signal *asig* or *ksig* through *iocts* of successive octave decimation and downsampling, and preserves a buffer of down-sampled values in each octave (optionally displayed as a composite buffer every *idisprd* seconds). Then at every *iprd* seconds, the preserved samples are passed through a filter bank (*ifrq*s parallel filters per octave, exponentially spaced, with frequency/bandwidth Q of *iq*), and the output magnitudes optionally converted (*idbout*) to produce a band-limited spectrum that can be read by other units.

The stages in this process are computationally intensive, and computation time varies directly with *iocts*, *ifrq*s, *iq*, and inversely with *iprd*. Settings of *ifrq*s = 12, *iq* = 10, *idbout* = 3, and *iprd* = .02 will normally be adequate, but experimentation is encouraged. *ifrq*s currently has a maximum of 120 divisions per octave. For audio input, the frequency bins are tuned to coincide with A440.

This unit produces a self-defining spectral datablock *wsig*, whose characteristics used (*iprd*, *iocts*, *ifrq*s, *idbout*) are passed via the data block itself to all derivative *wsigs*. There can be any number of *spectrum*

units in an instrument or orchestra, but all *wsig* names must be unique.

## Examples

```
asig in  
wsig spectrum asig, 0.02, 6, 12, 33, 0, 1, 1 ; get external audio  
; downsample in 6 octs & calc a 72 pt dft  
; (Q 33, dB out) every 20 msec
```

# splitrig

**splitrig** — Split a trigger signal

## Description

*splitrig* splits a trigger signal (i.e. a timed sequence of control-rate impulses) into several channels following a structure designed by the user.

## Syntax

```
splitrig ktrig, kndx, imaxtics, ifn, kout1 [,kout2,...,koutN]
```

## Initialization

*imaxtics* - number of tics belonging to largest pattern

*ifn* - number of table containing channel-data structuring

## Performance

*asig* - incoming (input) signal

*ktrig* - trigger signal

The *splitrig* opcode splits a trigger signal into several output channels according to one or more patterns provided by the user. Normally the regular timed trigger signal generated by metro opcode is used to be transformed into rhythmic pattern that can trig several independent melodies or percussion riffs. But you can also start from non-isocronous trigger signals. This allows to use some "interpretative" and less "mechanic" groove variations. Patterns are looped and each *numtics\_of\_pattern\_N* the cycle is repeated.

The scheme of patterns is defined by the user and is stored into *ifn* table according to the following format:

```
g1  ftgen 1,0,1024, -2 \ ; table is generated with GEN02 in this case
 \
numtics_of_pattern_1, \ ;pattern 1
  tic1_out1, tic1_out2, ... , tic1_outN,\ 
  tic2_out1, tic2_out2, ... , tic2_outN,\ 
  tic3_out1, tic3_out2, ... , tic3_outN,\ 
  ....
  ticN_out1, ticN_out2, ... , ticN_outN,\ 
 \
numtics_of_pattern_2, \ ;pattern 2
  tic1_out1, tic1_out2, ... , tic1_outN,\ 
  tic2_out1, tic2_out2, ... , tic2_outN,\ 
  tic3_out1, tic3_out2, ... , tic3_outN,\ 
  ....
  ticN_out1, ticN_out2, ... , ticN_outN,\ 
  ....
 \
numtics_of_pattern_N, \ ;pattern N
  tic1_out1, tic1_out2, ... , tic1_outN,\ 
  tic2_out1, tic2_out2, ... , tic2_outN,\ 
  tic3_out1, tic3_out2, ... , tic3_outN,\ 
  ....
  ticN_out1, ticN_out2, ... , ticN_outN,\
```

This scheme can contain more than one pattern, each one with a different number of rows. Each pattern is preceded by a special row containing a single *numtics\_of\_pattern\_N* field; this field expresses the number of tics that makes up the corresponding pattern. Each pattern's row makes up a tic. Each pattern's column corresponds to a channel, and each field of a row is a number that makes up the value outputted by the corresponding *koutXX* channel (if number is a zero, corresponding output channel will not trigger anything in that particular arguments). Obviously, all rows must contain the same number of fields that must be equal to the number of *koutXX* channel. All patterns must contain the same number of rows, this number must be equal to the largest pattern and is defined by *imaxtics* variable. Even if a pattern has less tics than the largest pattern, it must be made up of the same number of rows, in this case, some of these rows, at the end of the pattern itself, will not be used (and can be set to any value, because it doesn't matter).

The *kndx* variable chooses the number of the pattern to be played, zero indicating the first pattern. Each time the integer part of *kndx* changes, tic counter is reset to zero.

Patterns are looped and each *numtics\_of\_pattern\_N* the cycle is repeated.

examples 4 - calculate average value of asig in the time interval

This opcode can be useful in several situations, for example to implement a vu-meter

# sprintf

`sprintf` — printf-style formatted output to a string variable.

## Description

*sprintf* write printf-style formatted output to a string variable, similarly to the C function `sprintf()`. *sprintf* runs at i-time only.

## Syntax

```
Sdst sprintf Sfmt, xarg1[, xarg2[, ... ]]
```

## Initialization

*Sfmt* -- format string, has the same format as in `printf()` and other similar C functions, except length modifiers (l, ll, h, etc.) are not supported. The following conversion specifiers are allowed:

- d, i, o, u, x, X, e, E, f, F, g, G, c, s

*xarg1, xarg2, ...* -- input arguments (max. 30) for format, should be i-rate for all conversion specifiers except %s, which requires a string argument. Integer formats like %d round the input values to the nearest integer.

## Performance

*Sdst* -- output string variable

## Examples

Here is an example of the `sprintf` opcode. It uses the file `sprintf.csd` [examples/sprintf.csd].

### Example 838. Example of the `sprintf` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# sprintfk

`sprintfk` — printf-style formatted output to a string variable at k-rate.

## Description

*sprintfk* writes printf-style formatted output to a string variable, similarly to the C function `sprintf()`. *sprintfk* runs both at initialization and performance time.

## Syntax

```
Sdst sprintfk Sfmt, xarg1[, xarg2[, ... ]]
```

## Initialization

*Sfmt* -- format string, has the same format as in `printf()` and other similar C functions, except length modifiers (l, ll, h, etc.) are not supported. The following conversion specifiers are allowed:

- d, i, o, u, x, X, e, E, f, F, g, G, c, s

*xarg1, xarg2, ...* -- input arguments (max. 30) for format, should be i-rate for all conversion specifiers except %s, which requires a string argument. *sprintfk* also allows k-rate number arguments, but these should still be valid at init time as well (unless *sprintfk* is skipped with `igoto`). Integer formats like %d round the input values to the nearest integer.

## Performance

*Sdst* -- output string variable

## Examples

Here is an example of the *sprintfk* opcode. It uses the file *sprintfk.csd* [examples/sprintfk.csd].

### Example 839. Example of the *sprintfk* opcode.

# spsend

**spsend** — Generates output signals based on a previously defined *space* opcode.

## Description

*spsend* depends upon the existence of a previously defined *space*. The output signals from *spsend* are derived from the values given for xy and reverb in the *space* and are ready to be sent to local or global reverb units (see example below).

## Syntax

```
a1, a2, a3, a4 spsend
```

## Performance

The configuration of the xy coordinates in space places the signal in the following way:

- a1 is -1, 1
- a2 is 1, 1
- a3 is -1, -1
- a4 is 1, -1

This assumes a loudspeaker set up as a1 is left front, a2 is right front, a3 is left back, a4 is right back. Values greater than 1 will result in sounds being attenuated, as if in the distance. *space* considers the speakers to be at a distance of 1; smaller values of xy can be used, but *space* will not amplify the signal in this case. It will, however balance the signal so that it can sound as if it were within the 4 speaker *space*. x=0, y=1, will place the signal equally balanced between left and right front channels, x=y=0 will place the signal equally in all 4 channels, and so on. Although there must be 4 output signals from *space*, it can be used in a 2 channel orchestra. If the xy's are kept so that Y>=1, it should work well to do panning and fixed localization in a stereo field.

## Examples

Here is a stereo example of the spsend opcode. It uses the file *spsend.csd* [examples/spsend.csd].

# Sqrt

**sqrt** — Returns a square root value.

## Description

Returns the square root of  $x$  ( $x$  non-negative).

The argument value is restricted for  $\log$ ,  $\log10$ , and  $\sqrt$ .

## Syntax

```
sqrt(x) (no rate restriction)
```

where the argument within the parentheses may be an expression. Value converters perform arithmetic translation from units of one kind to units of another. The result can then be a term in a further expression.

## Examples

Here is an example of the `sqrt` opcode. It uses the file `sqrt.csd` [examples/sqrt.csd].

### Example 841. Example of the sqrt opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## Sr

**sr** — Sets the audio sampling rate.

## Description

These statements are global value *assignments*, made at the beginning of an orchestra, before any instrument block is defined. Their function is to set certain *reserved symbol variables* that are required for performance. Once set, these reserved symbols can be used in expressions anywhere in the orchestra.

## Syntax

```
sr = iarg
```

## Initialization

*sr* = (optional) -- set sampling rate to *iarg* samples per second per channel. The default value is 44100.

In addition, any *global variable* [55] can be initialized by an *init-time assignment* anywhere before the first *instr statement*. All of the above assignments are run as instrument 0 (i-pass only) at the start of real performance.

Beginning with Csound version 3.46, *sr* may be omitted. The sample rate will be calculated from *kr* and *ksmps*, but this must evaluate to an integer. If none of these global values is defined, the sample rate will default to 44100. You will usually want to use a value that your soundcard supports, like 44100 or 48000, otherwise, the audio generated by csound may be unplayable, or you will get an error if you attempt to run in real-time. You may naturally use a sample rate like 96000, for off-line rendering even if your soundcard doesn't support it. Csound will generate a valid file that can be played on capable systems.

## Examples

```
sr = 10000
kr = 500
ksmps = 20
gil = sr/2.
ga init 0
itranspose = octpch(.01)
```

Here is another example of the *sr* opcode. It uses the file *sr.csd* [examples/sr.csd].

### Example 842. Example of the sr opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# statevar

`statevar` — State-variable filter.

## Description

`Statevar` is a new digital implementation of the analogue state-variable filter. This filter has four simultaneous outputs: high-pass, low-pass, band-pass and band-reject. This filter uses oversampling for sharper resonance (default: 3 times oversampling). It includes a resonance limiter that prevents the filter from getting unstable.

## Syntax

```
ahp,alp,abp,abr statevar ain, xcf, xq [, iosamps, istor]
```

## Initialization

*iosamps* -- number of times of oversampling used in the filtering process. This will determine the maximum sharpness of the filter resonance (Q). More oversampling allows higher Qs, less oversampling will limit the resonance. The default is 3 times (iosamps=0).

*istor* --initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*ahp* -- high-pass output signal.

*alp* -- low-pass output signal.

*abp* -- band-pass signal.

*abr* -- band-reject signal.

*asig* -- input signal.

*xcf* -- filter cutoff frequency (k-rate or a-rate).

*xq* -- filter Q (k-rate or a-rate). This value is limited internally depending on the frequency and the number of times of oversampling used in the process (3-times oversampling by default).

## Examples

Here is an example of the `statevar` opcode. It uses the file `statevar.csd` [examples/statevar.csd].

### Example 843. Example of the `statevar` opcode.

# stix

stix — Semi-physical model of a stick sound.

## Description

*stix* is a semi-physical model of a stick sound. It is one of the PhISEM percussion opcodes. PhISEM (Physically Informed Stochastic Event Modeling) is an algorithmic approach for simulating collisions of multiple independent sound producing objects.

## Syntax

```
ares stix iamp, idettack [, inum] [, idamp] [, imaxshake]
```

## Initialization

*iamp* -- Amplitude of output. Note: As these instruments are stochastic, this is only a approximation.

*idettack* -- period of time over which all sound is stopped

*inum* (optional) -- The number of beads, teeth, bells, timbrels, etc. If zero, the default value is 30.

*idamp* (optional) -- the damping factor, as part of this equation:

$$\text{damping\_amount} = 0.998 + (\text{idamp} * 0.002)$$

The default *damping\_amount* is 0.998 which means that the default value of *idamp* is 0. The maximum *damping\_amount* is 1.0 (no damping). This means the maximum value for *idamp* is 1.0.

The recommended range for *idamp* is usually below 75% of the maximum value.

*imaxshake* (optional) -- amount of energy to add back into the system. The value should be in range 0 to 1.

## Examples

Here is an example of the stix opcode. It uses the file *stix.csd* [examples/stix.csd].

### Example 844. Example of the stix opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# STKBandedWG

STKBandedWG — STKBandedWG uses banded waveguide techniques to model a variety of sounds.

## Description

This opcode uses banded waveguide techniques to model a variety of sounds, including bowed bars, glasses, and bowls.

## Syntax

```
asignal STKBandedWG ifrequency, iamplitude, [kpress, kv1[], kmot, kv2[], klflo, kv3[], klfodepth, kv4[], kve
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kpress* -- controller 2, pressure of bow. Value range of kv1 is 0-127.

*kmot* -- controller 4, motion of bow. Value range of kv2 is 0-127.

*klflo* -- controller 11, speed of low-frequency oscillator. Value range of kv3 is 0-127.

*klfodepth* -- controller 1, depth of low-frequency oscillator. Value range of kv4 is 0-127.

*kvel* -- controller 128, velocity of bow. Value range of kv5 is 0-127.

*kstrk* -- controller 64, striking of bow. Value range of kv6 is 0-127.

*kinstr* -- controller 16, instrument presets (0 = uniform bar, 1 = tuned bar, 2 = glass harmonica, 3 = Tibetan bowl). Value range of kv7 is 0-3.

## Notes

The code for this opcode is taken directly from the BandedWG class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

*kc1, kv1, kc2, kv2, kc3, kv3, kc4, kv4, kc5, kv5, kc6, kv6, kc7, kv7, kc8, kv8* -- Up to 8 optional k-rate controller pairs for the STK opcodes. Each controller pair consists of a controller number (kc) followed by a controller value (kv). Both the controller numbers and the controller values are krate variables. However, during a performance, normally the controller numbers stay fixed while the corresponding controller values may change at any time. The order of the controller pair is arbitrary, as long as they are after *iamplitude*. Also, it is not needed that all controller pairs are used.

## Examples

Here is an example of the STKBandedWG opcode. It uses the file *STKBandedWG.csd* [examples/*STKBandedWG.csd*].

# STKBeeThree

STKBeeThree — STK Hammond-oid organ-like FM synthesis instrument.

## Description

STK Hammond-oid organ-like FM synthesis instrument.

This opcode a simple 4 operator topology, also referred to as algorithm 8 of the TX81Z. It simulates the sound of a Hammond-oid organ, and some related sounds.

## Syntax

```
asignal STKBeeThree ifrequency, iamplitude, [kop4, kv1[], kop3, kv2[], klf0, kv3[], klfodepth, kv4[], kadsr]
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kop4* -- controller 2, gain of feedback of operator 4. Value range of *kv1* is 0-127.

*kop3* -- controller 4, gain of operator 3. Value range of *kv2* is 0-127.

*klfo* -- controller 11, speed of low-frequency oscillator. Value range of *kv3* is 0-127.

*klfodepth* -- controller 1, depth of low-frequency oscillator. Value range of *kv4* is 0-127.

*kadsr* -- controller 128, ADSR 2 and 4 target. Value range of *kv5* is 0-127.

## Notes

The code for this opcode is taken directly from the BeeThree class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

*kc1, kv1, kc2, kv2, kc3, kv3, kc4, kv4, kc5, kv5, kc6, kv6, kc7, kv7, kc8, kv8* -- Up to 8 optional k-rate controller pairs for the STK opcodes. Each controller pair consists of a controller number (kc) followed by a controller value (kv). Both the controller numbers and the controller values are krate variables. However, during a performance, normally the controller numbers stay fixed while the corresponding controller values may change at any time. # STKBlowBotl

STKBlowBotl — STKBlowBotl uses a helmholtz resonator (biquad filter) with a polynomial jet excitation.

## Description

This opcode implements a helmholtz resonator (biquad filter) with a polynomial jet excitation (a la Cook).

## Syntax

```
asignal STKBlowBotl ifrequency, iamplitude, [knoise, kv1[, klfo, kv2[, klfodepth, kv3[, kvol, kv4]]]]
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*knoise* -- controller 4, gain of noise. Value range of kv1 is 0-127.

*klfo* -- controller 11, speed of low-frequency oscillator. Value range of kv2 is 0-127.

*klfodepth* -- controller 1, depth of low-frequency oscillator. Value range of kv3 is 0-127.

*kvol* -- controller 128, volume. Value range of kv4 is 0-127.

## Notes

The code for this opcode is taken directly from the BlowBotl class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

*kc1, kv1, kc2, kv2, kc3, kv3, kc4, kv4, kc5, kv5, kc6, kv6, kc7, kv7, kc8, kv8* -- Up to 8 optional k-rate controller pairs for the STK opcodes. Each controller pair consists of a controller number (kc) followed by a controller value (kv). Both the controller numbers and the controller values are krate variables. However, during a performance, normally the controller numbers stay fixed while the corresponding controller values may change at any time. The order of the controller pair is arbitrary, as long as they are after *iamplitude*. Also, it is not needed that all controller pairs are used.

# STKBlowHole

STKBlowHole — STK clarinet physical model with one register hole and one tonehole.

## Description

This opcode is based on the clarinet model, with the addition of a two-port register hole and a three-port dynamic tonehole implementation.

In this implementation, the distances between the reed/register hole and tonehole/bell are fixed. As a result, both the tonehole and register hole will have variable influence on the playing frequency, which is dependent on the length of the air column. In addition, the highest playing frequency is limited by these fixed lengths.

## Syntax

```
asignal STKBlowHole ifrequency, iamplitude, [kreed, kv1[, knoise, kv2[, khole, kv3[, kreg, kv4[, kbreat
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kreed* -- controller 2, stiffness of reed. Value range of kv1 is 0-127.

*knoise* -- controller 4, gain of noise. Value range of kv2 is 0-127.

*khole* -- controller 11, state of tonehole. Value range of kv3 is 0-127.

*kreg* -- controller 1, state of register. Value range of kv4 is 0-127.

*kbreath* -- controller 128, breath pressure. Value range of kv5 is 0-127.

## Notes

The code for this opcode is taken directly from the BlowHole class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

*kc1, kv1, kc2, kv2, kc3, kv3, kc4, kv4, kc5, kv5, kc6, kv6, kc7, kv7, kc8, kv8* -- Up to 8 optional k-rate controller pairs for the STK opcodes. Each controller pair consists of a controller number (kc) followed by a controller value (kv). Both the controller numbers and the controller values are krate variables. However, during a performance, normally the controller numbers stay fixed while the corresponding controller values may change at any time. # STKClarinet

STKClarinet — STKClarinet uses a simple clarinet physical model.

## Description

STKClarinet uses a simple clarinet physical model.

## Syntax

```
asignal STKClarinet ifrequency, iamplitude, [kstiff, kv1[], knoise, kv2[], klfo, kv3[], klfodepth, kv4[], kbreath]
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kstiff* -- controller 2, reed stiffness. Value range of kv1 is 0-127.

*knoise* -- controller 4, gain of noise. Value range of kv2 is 0-127.

*klfo* -- controller 11, speed of low-frequency oscillator. Value range of kv3 is 0-127.

*klfodepth* -- controller 1, depth of low-frequency oscillator. Value range of kv4 is 0-127.

*kbreath* -- controller 128, breath pressure. Value range of kv5 is 0-127.

### Note

The code for this opcode is taken directly from the Clarinet class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

*kc1, kv1, kc2, kv2, kc3, kv3, kc4, kv4, kc5, kv5, kc6, kv6, kc7, kv7, kc8, kv8* -- Up to 8 optional k-rate controller pairs for the STK opcodes. Each controller pair consists of a controller number (kc) followed by a controller value (kv). Both the controller numbers and the controller values are krate variables. However, during a performance, normally the controller numbers stay fixed while the corresponding controller values may change at any time. The order of the controller pair is arbitrary, as long as they are after *iamplitude*. Also, it is not needed that all controller pairs are used.

## Examples

Here is an example of the STKClarinet opcode. It uses the file *STKClarinet.csd* [examples/STKClarinet.csd].

# STKDrummer

STKDrummer — STKDrummer is a drum sampling synthesizer.

## Description

STKDrummer is a drum sampling synthesizer using raw waves and one-pole filters. The drum rawwave files are sampled at 22050 Hz, but will be appropriately interpolated for other sample rates.

## Syntax

```
asignal STKDrummer ifrequency, iamplitude
```

## Initialization

*ifrequency* -- Samples being played.

*iamplitude* -- Amplitude of note played (range 0-1).

### Note

The code for this opcode is taken directly from the Drummer class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

# STKFlute

STKFlute — STKFlute uses a simple flute physical model.

## Description

STKFlute uses a simple flute physical model. The jet model uses a polynomial, a la Cook.

## Syntax

```
asignal STKFlute ifrequency, iamplitude, [kjet, kv1[], knoise, kv2[], klfo, kv3[], klfodepth, kv4[], kbreat
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kjet* -- controller 2, jet delay. Value range of kv1 is 0-127.

*knoise* -- controller 4, gain of noise. Value range of kv2 is 0-127.

*klfo* -- controller 11, speed of low-frequency oscillator. Value range of kv3 is 0-127.

*klfodepth* -- controller 1, depth of low-frequency oscillator. Value range of kv4 is 0-127.

*kbreath* -- controller 128, breath pressure. Value range of kv5 is 0-127.

### Note

The code for this opcode is taken directly from the Flute class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

*kc1, kv1, kc2, kv2, kc3, kv3, kc4, kv4, kc5, kv5, kc6, kv6, kc7, kv7, kc8, kv8* -- Up to 8 optional k-rate controller pairs for the STK opcodes. Each controller pair consists of a controller number (kc) followed by a controller value (kv). Both the controller numbers and the controller values are krate variables. However, during a performance, normally the controller numbers stay fixed while the corresponding controller values may change at any time. The order of the controller pair is arbitrary, as long as they are after *iamplitude*. Also, it is not needed that all controller pairs are used.

# STKFMVoices

STKFMVoices — STKFMVoices is a singing FM synthesis instrument.

## Description

STKFMVoices is a singing FM synthesis instrument. It has 3 carriers and a common modulator, also referred to as algorithm 6 of the TX81Z.

## Syntax

```
asignal STKFMVoices ifrequency, iamplitude, [kvowel, kv1[], kspec, kv2[], klfo, kv3[], klfodepth, kv4[], ka
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kvowel* -- controller 2, vowel. Value range of kv1 is 0-127.

*kspec* -- controller 4, spectral tilt. Value range of kv2 is 0-127.

*klfo* -- controller 11, speed of low-frequency oscillator. Value range of kv3 is 0-127.

*klfodepth* -- controller 1, depth of low-frequency oscillator. Value range of kv4 is 0-127.

*kadsr* -- controller 128, ADSR 2 and 4 Target. Value range of kv5 is 0-127.

### Note

# STKHevyMetI

**STKHevyMetl** — STKHevyMetl produces metal sounds.

## Description

STKHevyMetl produces metal sounds, using FM synthesis. It uses 3 cascade operators with feedback modulation, also referred to as algorithm 3 of the TX81Z.

# Syntax

```
asignal STKHeavyMetal ifrequency, iamplitude, [kmod, kv1[], kcros, kv2[], klf, kv3[], klfodepth, kv4[], kad,
```

# Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kmod* -- controller2, total modulator index. Value range of kv1 is 0-127.

*kcross* -- controller 4, crossfade of modulator. Value range of kv2 is 0-127.

*klfo* -- controller 11, speed of low-frequency oscillator. Value range of kv3 is 0-127.

*klfodepth* -- controller 1, depth of low-frequency oscillator. Value range of kv4 is 0-127.

*kadsr* -- controller 128, ADSR 2 and 4 target. Value range of kv5 is 0-127.

## Note

The code for this opcode is taken directly from the HevyMetl class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrrma.stanford.edu/software/stk/classes.html>

*kc1, kv1, kc2, kv2, kc3, kv3, kc4, kv4, kc5, kv5, kc6, kv6, kc7, kv7, kc8, kv8* -- Up to 8 optional k-rate controller pairs for the STK opcodes. # STKMandolin

STKMandolin — STKMandolin produces mandolin-like sounds.

## Description

STKMandolin produces mandolin-like sounds, using "commuted synthesis" techniques to model a mandolin instrument.

## Syntax

```
asignal STKMandolin ifrequency, iamplitude, [kbody, kv1[, kpos, kv2[, ksus, kv3[, kdetune, kv4[, kmic,
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kbody* -- controller 2, size of body. Value range of kv1 is 0-127.

*kpos* -- controller 4, pluck position. Value range of kv2 is 0-127.

*ksus* -- controller 11, string sustain. Value range of kv3 is 0-127.

*kdetune* -- controller 1, string detuning. Value range of kv4 is 0-127.

*kmic* -- controller 128, position of microphone. Value range of kv5 is 0-127.

### Note

The code for this opcode is taken directly from the Mandolin class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

*kc1, kv1, kc2, kv2, kc3, kv3, kc4, kv4, kc5, kv5, kc6, kv6, kc7, kv7, kc8, kv8* -- Up to 8 optional k-rate controller pairs for the STK opcodes. Each controller pair consists of a controller number (kc) followed by a controller value (kv). Both the controller numbers and the controller values are krate variables. However, during a performance, normally the controller numbers stay fixed while the corresponding controller values may change at any time. The order of the controller pair is arbitrary, as long as they are after *iamplitude*. Also, it is not needed that all controller pairs are used.

# STKModalBar

STKModalBar — STKModalBar is a resonant bar instrument.

## Description

This opcode is a resonant bar instrument. It has a number of different struck bar instruments.

## Syntax

```
asignal STKModalBar ifrequency, iamplitude, [khard, kv1[], kpos, kv2[], kflo, kv3[], klfodepth, kv4[], kmix]
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*khard* -- controller 2, hardness of the stick. Value range of kv1 is 0-127.

*kpos* -- controller 4, stick position. Value range of kv2 is 0-127.

*kflo* -- controller 11, speed of low-frequency oscillator. Value range of kv3 is 0-127.

*klfodepth* -- controller 1, depth of low-frequency oscillator. Value range of kv4 is 0-127.

*kmix* -- controller 8, direct stick mix. Value range of kv5 is 0-127.

*kvol* -- controller 128, volume. Value range of kv6 is 0-127.

*kinstr* -- controller 16, instrument presets (0 = marimba, 1 = vibraphone, 2 = agogo, 3 = wood1, 4 = reso, 5 = wood2, 6 = beats, 7 = two fixed, 8 = clump). Value range of kv7 is 0-16.

### Note

# STKMoog

STKMoog — STKMoog produces moog-like swept filter sounds.

## Description

STKMoog produces moog-like swept filter sounds, using one attack wave, one looped wave, and an ADSR envelope and adds two sweepable formant filters.

## Syntax

```
asignal STKMoog ifrequency, iamplitude, [kq, kv1[, krate, kv2[, klfo, kv3[, klfodepth, kv4[, kvol, kv5[
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kq* -- controller 2, Q filter. Value range of kv1 is 0-127.

*krate* -- controller 4, rate of filter sweep. Value range of kv2 is 0-127.

*klfo* -- controller 11, speed of low-frequency oscillator. Value range of kv3 is 0-127.

*klfodepth* -- controller 1, depth of low-frequency oscillator. Value range of kv4 is 0-127.

*kvol* -- controller 128, volume. Value range of kv5 is 0-127.

### Note

The code for this opcode is taken directly from the Moog class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

*kc1, kv1, kc2, kv2, kc3, kv3, kc4, kv4, kc5, kv5, kc6, kv6, kc7, kv7, kc8, kv8* -- Up to 8 optional k-rate controller pairs for the STK opcodes. Each controller pair consists of a controller number (kc) followed by a controller value (kv). Both the controller numbers and the controller values are krate variables. However, during a performance, normally the controller numbers stay fixed while the corresponding controller values may change at any time. The order of the controller pair is arbitrary, as long as they are after *iamplitude*. Also, it is not needed that all controller pairs are used.

# STKPercFlut

STKPercFlut — STKPercFlut is a percussive flute FM synthesis instrument.

## Description

STKPercFlut is a percussive flute FM synthesis instrument. The instrument uses an algorithm like the algorithm 4 of the TX81Z.

## Syntax

```
asignal STKPercFlut ifrequency, iamplitude, [kmod, kv1[, kcross, kv2[, klflo, kv3[, klfodepth, kv4[, kadsr[, krate]]]]]]
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kmod* -- controller 2, total modulator index. Value range of kv1 is 0-127.

*kcross* -- controller 4, crossfade of modulator. Value range of kv2 is 0-127.

*klflo* -- controller 11, speed of low-frequency oscillator. Value range of kv3 is 0-127.

*klfodepth* -- controller 1, depth of low-frequency oscillator. Value range of kv4 is 0-127.

*kadsr* -- controller 128, ADSR 2 and 4 target. Value range of kv5 is 0-127.

### Note

The code for this opcode is taken directly from the PercFlut class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

*kc1, kv1, kc2, kv2, kc3, kv3, kc4, kv4, kc5, kv5, kc6, kv6, kc7, kv7, kc8, kv8* -- Up to 8 optional k-rate controller pairs for the STK opcodes. Each controller pair consists of a controller number (kc) followed by a controller value (kv). Both the controller numbers and the controller values are krate variables. However, during a performance, normally the controller numbers stay fixed while the corresponding controller values may change at any time. The order of the controller pair is arbitrary, as long as they are after *iamplitude*. Also, it is not needed that all controller pairs are used.

## Examples

Here is an example of the STKPercFlut opcode. It uses the file *STKPercFlut.csd* [examples/STKPercFlut.csd].

# STKResonate

STKResonate — STKResonate is a noise driven formant filter.

## Description

STKResonate is a noise driven formant filter. This instrument contains a noise source, which excites a biquad resonance filter, with volume controlled by an ADSR.

## Syntax

```
asignal STKResonate ifrequency, iamplitude, [kfreq, kv1[, kpole, kv2[, knotch, kv3[, kzero, kv4[, kenv,
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kfreq* -- controller 2, frequency of resonance. Value range of kv1 is 0-127.

*kpole* -- controller 4, pole radii. Value range of kv2 is 0-127.

*knotch* -- controller 11, notch frequency. Value range of kv3 is 0-127.

*kzero* -- controller 1, zero radii. Value range of kv4 is 0-127.

*kenv* -- controller 128, gain of envelope. Value range of kv5 is 0-127.

### Note

The code for this opcode is taken directly from the Resonate class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

# STKRhodey

STKRhodey — STK Fender Rhodes-like electric piano FM synthesis instrument.

## Description

STK Fender Rhodes-like electric piano FM synthesis instrument.

This opcode implements an instrument based on two simple FM Pairs summed together, also referred to as algorithm 5 of the Yamaha TX81Z. It simulates the sound of a Rhodes electric piano, and some related sounds.

## Syntax

```
asignal STKRhodey ifrequency, iamplitude, [kmod, kv1[, kcros
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kmod* -- controller 2, modulator index 1. Value range of kv1 is 0-127.

*kcross* -- controller 4, crossfade of outputs. Value range of kv2 is 0-127.

*klfo* -- controller 11, speed of low-frequency oscillator. Value range of kv3 is 0-127.

*klfodepth* -- controller1, depth of low-frequency oscillator. Value range of kv4 is 0-127.

*kadsr* -- controller 128, ADSR 2 and 4 target. Value range of kv5 is 0-127.

### Note

The code for this opcode is taken directly from the Rhodey class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

# STKSaxofony

STKSaxofony — STKSaxofony is a faux conical bore reed instrument.

## Description

STKSaxofony is a faux conical bore reed instrument. This opcode uses a "hybrid" digital waveguide instrument that can generate a variety of wind-like sounds. It has also been referred to as the "blown string" model. The waveguide section is essentially that of a string, with one rigid and one lossy termination. The non-linear function is a reed table. The string can be "blown" at any point between the terminations, though just as with strings, it is impossible to excite the system at either end. If the excitation is placed at the string mid-point, the sound is that of a clarinet. At points closer to the "bridge", the sound is closer to that of a saxophone.

## Syntax

```
asignal STKSaxofony ifrequency, iamplitude, [kstiff, kv1[, kapert, kv2[, kblow, kv3[, knoise, kv4[, klf
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kstiff* -- controller 2, stiffness of reed. Value range of kv1 is 0-127.

*kapert* -- controller 26, reed aperture. Value range of kv2 is 0-127.

*kblow* -- controller 11, blow position. Value range of kv3 is 0-127.

*knoise* -- controller 4, noise gain. Value range of kv4 is 0-127.

*klf* -- controller 29, speed of low-frequency oscillator. Value range of kv5 is 0-127.

*klfodepth* -- controller 1, depth of low-frequency oscillator. Value range of kv6 is 0-127.

*kbreath* -- controller 128, breath pressure. Value range of kv7 is 0-127.

### Note

The code for this opcode is taken directly from the Saxofony class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

*kc1, kv1, kc2, kv2, kc3, kv3, kc4, kv4, kc5, kv5, kc6, kv6, kc7, kv7, kc8, kv8* -- Up to 8 optional k-rate controller pairs for the STK opcodes. Each controller pair consists of a controller number (kc) followed by a controller value (kv). Both the controller numbers and the controller values are krate variables. However, during a performance, normally the controller numbers stay fixed while the corresponding controller values may change at any time. The order of the controller pair is arbitrary, as long as they are after *iamplitude*. Also, it is not needed that all controller pairs are used.

# STKShakers

STKShakers — STKShakers is an instrument that simulates environmental sounds or collisions of multiple independent sound producing objects.

## Description

STKShakers are a set of PhISEM and PhOLIES instruments: PhISEM (Physically Informed Stochastic Event Modeling) is an algorithmic approach for simulating collisions of multiple independent sound producing objects. It can simulate a Maraca, Sekere, Cabasa, Bamboo Wind Chimes, Water Drops, Tambourine, Sleighbells, and a Guiro. On <http://soundlab.cs.princeton.edu/research/controllers/shakers/> PhOLIES (Physically-Oriented Library of Imitated Environmental Sounds) there is a similar approach for the synthesis of environmental sounds. It simulates of breaking sticks, crunchy snow (or not), a wrench, sandpaper, and more..

## Syntax

```
asignal STKShakers ifrequency, iamplitude, [kenerg, kv1[, kdecay, kv2[, kshake, kv3[, knum, kv4[, kres,
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kenerg* -- controller 2, shake energy. Value range of kv1 is 0-127.

*kdecay* -- controller 4, system decay. Value range of kv2 is 0-127.

*kshake* -- controller 128, shake energy. Value range of kv3 is 0-127.

*knum* -- controller 11, number of objects. Value range of kv4 is 0-127.

*kres* -- controller 1, resonance frequency. Value range of kv5 is 0-127.

*kinstr* -- controller 1071, instrument selection (Maraca = 0, Cabasa = 1, Sekere = 2, Guiro = 3, Water Drops = 4, Bamboo Chimes = 5, Tambourine = 6, Sleigh Bells = 7, Sticks = 8, Crunch = 9, Wrench = 10, Sand Paper = 11, Coke Can = 12, Next Mug = 13, Penny + Mug = 14, Nickle + Mug = 15, Dime + Mug = 16, Quarter + Mug = 17, Franc + Mug = 18, Peso + Mug = 19, Big Rocks = 20, Little Rocks = 21, Tuned Bamboo Chimes = 22). Value range of kv6 is 0-22.

### Note

The code for this opcode is taken directly from the Shakers class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

*kc1, kv1, kc2, kv2, kc3, kv3, kc4, kv4, kc5, kv5, kc6, kv6, kc7, kv7, kc8, kv8* -- Up to 8 optional k-rate controller pairs for the STK opcodes. Each controller pair consists of a controller number (kc) followed by a controller value (kv). Both the controller numbers and the controller values are krate variables. However, during a performance, normally the

controller numbers stay fixed while the corresponding controller values may change at any time. The order of the controller pair is arbitrary, as long as they are after *iamplitude*. Also, it is not needed that all controller pairs are used.

# STKSimple

STKSimple — STKSimple is a wavetable/noise instrument.

## Description

STKSimple is a wavetable/noise instrument. It combines a looped wave, a noise source, a biquad resonance filter, a one-pole filter, and an ADSR envelope to create some interesting sounds.

## Syntax

```
asignal STKSimple ifrequency, iamplitude, [kpos, kv1[, kcross, kv2[, kenv, kv3[, kgain, kv4]]]]
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kpos* -- controller 2, position of filter pole. Value range of kv1 is 0-127.

*kcross* -- controller 4, noise/pitched cross-fade. Value range of kv2 is 0-127.

*kenv* -- controller 11, rate of envelope. Value range of kv3 is 0-127.

*kgain* -- controller 128, gain. Value range of kv4 is 0-127.

### Note

The code for this opcode is taken directly from the Simple class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

# STKStifKarp

STKStifKarp — STKStifKarp is a plucked stiff string instrument.

## Description

STKStifKarp is a plucked stiff string instrument. It uses a simple plucked string algorithm (Karplus Strong) with enhancements, including string stiffness and pluck position controls. The stiffness is modeled with allpass filters.

## Syntax

```
asignal STKStifKarp ifrequency, iamplitude, [kpos, kv1[, ksus, kv2[, kstretch, kv3]]]
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kpos* -- controller 4, pickup position. Value range of kv1 is 0-127.

*ksus* -- controller 11, string sustain. Value range of kv2 is 0-127.

*kstretch* -- controller 1, string stretch. Value range of kv3 is 0-127.

### Note

The code for this opcode is taken directly from the StifKarp class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

*kc1, kv1, kc2, kv2, kc3, kv3, kc4, kv4, kc5, kv5, kc6, kv6, kc7, kv7, kc8, kv8* -- Up to 8 optional k-rate controller pairs for the STK opcodes. Each controller pair consists of a controller number (kc) followed by a controller value (kv). Both the controller numbers and the controller values are krate variables. However, during a performance, normally the controller numbers stay fixed while the corresponding controller values may change at any time. The order of the controller pair is arbitrary, as long as they are after *iamplitude*. Also, it is not needed that all controller pairs are used.

## Examples

Here is an example of the STKStifKarp opcode. It uses the file *STKStifKarp.csd* [examples/STKStifKarp.csd].

# STKTubeBell

STKTubeBell — STKTubeBell is a tubular bell (orchestral chime) FM synthesis instrument.

## Description

STKTubeBell is a tubular bell (orchestral chime) FM synthesis instrument. It uses two simple FM Pairs summed together, also referred to as algorithm 5 of the TX81Z.

## Syntax

```
asignal STKTubeBell ifrequency, iamplitude, [kmod, kv1[, kcross, kv2[, klflo, kv3[, klfodepth, kv4[, kadsr[, krate]]]]]]
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kmod* -- controller 2, modulator index 1. Value range of kv1 is 0-127.

*kcross* -- controller 4, crossfade of outputs. Value range of kv2 is 0-127.

*klflo* -- controller 11, speed of low-frequency oscillator. Value range of kv3 is 0-127.

*klfodepth* -- controller 1, depth of low-frequency oscillator. Value range of kv4 is 0-127.

*kadsr* -- controller 128, ADSR 2 and 4 target. Value range of kv5 is 0-127.

### Note

The code for this opcode is taken directly from the TubeBell class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

# STKVocForm

STKVocForm — STKVocForm is a four formant synthesis instrument.

## Description

STKVocForm is a four formant synthesis instrument. This instrument contains an excitation singing wavetable (looping wave with random and periodic vibrato, smoothing on frequency, etc.), excitation noise, and four sweepable complex resonances. Measured formant data is included, and enough data is there to support either parallel or cascade synthesis. In the floating point case cascade synthesis is the most natural so that's what you'll find here.

## Syntax

```
asignal STKVocForm ifrequency, iamplitude, [kmix, kv1[], ksel, kv2[], klfo, kv3[], klfodepth, kv4[], kloud
```

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

## Performance

*kmix* -- controller 2, voiced/unvoiced mix. Value range of kv1 is 0-127.

*ksel* -- controller 4, vowel/phoneme selection. Value range of kv2 is 0-127.

*klfo* -- controller 11, speed of low-frequency oscillator. Value range of kv3 is 0-127.

*klfodepth* -- controller 1, depth of low-frequency oscillator. Value range of kv4 is 0-127.

*kloud* -- controller 128, loudness (spectral tilt). Value range of kv5 is 0-127.

### Note

The code for this opcode is taken directly from the VoicForm class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

*kc1, kv1, kc2, kv2, kc3, kv3, kc4, kv4, kc5, kv5, kc6, kv6, kc7, kv7, kc8, kv8* -- Up to 8 optional k-rate controller pairs for the STK opcodes. Each controller pair consists of a controller number (kc) followed by a controller value (kv). Both the controller numbers and the controller values are krate variables. However, during a performance, normally the controller numbers stay fixed while the corresponding controller values may change at any time. The order of the controller pair is arbitrary, as long as they are after *iamplitude*. Also, it is not needed that all controller pairs are used.

# STKWhistle

**STKWhistle** — STKWhistle produces whistle sounds.

## Description

STKWhistle produces (police) whistle sounds. It uses a hybrid physical/spectral model of a police whistle (a la Cook).

# Syntax

## Initialization

*ifrequency* -- Frequency of note played, in Hertz.

*iamplitude* -- Amplitude of note played (range 0-1).

# Performance

*kmod* -- controller 2, blowing frequency modulation. Value range of kv1 is 0-127.

*knoise* -- controller 4, noise gain. Value range of kv2 is 0-127.

*kfipfreq* -- controller 11, fipple modulation frequency. Value range of kv3 is 0-127.

*kfipgains* -- controller 1, fipple modulation gain. Value range of kv4 is 0-127.

*kvvol* -- controller 128, volume. Value range of kv5 is 0-127.

Note

The code for this opcode is taken directly from the Whistle class in the Synthesis Toolkit in C++ by Perry R. Cook and Gary P. Scavone. More on the STK classes can be found here: <https://ccrma.stanford.edu/software/stk/classes.html>

*kc1, kv1, kc2, kv2, kc3, kv3, kc4, kv4, kc5, kv5, kc6, kv6, kc7, kv7, kc8, kv8* -- Up to 8 optional k-rate controller pairs for the STK opcodes. Each controller pair consists of a controller number (kc) followed by a controller value (kv). Both the controller numbers and the controller values are krate variables. However, during a performance, normally the controller numbers stay fixed while the corresponding controller values may change at any time. The order of the controller pair is arbitrary, as long as they are after *iamplitude*. Also, it is not needed that all controller pairs are used.

# strcmp

strcmp — Compare strings

## Description

Compare strings and set the result to -1, 0, or 1 if the first string is less than, equal to, or greater than the second, respectively. strcmp compares at i-time only.

## Syntax

```
ires strcmp S1, S2
```

## Examples

Here is an example of the strcmp opcode. It uses the file *strcmp.csd* [examples/strcmp.csd].

### Example 876. Example of the strcmp opcode.

```

# strcmpk

stremp — Compare strings

## Description

Compare strings and set the result to -1, 0, or 1 if the first string is less than, equal to, or greater than the second, respectively. *strcmpk* does the comparison both at initialization and performance time.

## Syntax

```
kres strcmpk S1, S2
```

## See also

# streson

*streson* — A string resonator with variable fundamental frequency.

## Description

An audio signal is modified by a string resonator with variable fundamental frequency.

## Syntax

```
ares streson asig, kfr, ifdbgain
```

## Initialization

*ifdbgain* -- feedback gain, between 0 and 1, of the internal delay line. A value close to 1 creates a slower decay and a more pronounced resonance. Small values may leave the input signal unaffected. Depending on the filter frequency, typical values are > .9.

## Performance

*asig* -- the input audio signal.

*kfr* -- the fundamental frequency of the string.

*streson* passes the input *asig* through a network composed of comb, low-pass and all-pass filters, similar to the one used in some versions of the Karplus-Strong algorithm, creating a string resonator effect. The fundamental frequency of the “string” is controlled by the k-rate variable *kfr*. This opcode can be used to simulate sympathetic resonances to an input signal.

See *Modal Frequency Ratios* for frequency ratios of real instruments which can be used to determine the values of *kfrq*.

*streson* is an adaptation of the StringFlt object of the SndObj Sound Object Library developed by the author.

## Examples

Here is an example of the *streson* opcode. It uses the file *streson.csd* [examples/streson.csd].

### Example 877. Example of the streson opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# strfromurl

strfromurl — Set string variable to value read from an URL

## Description

*strfromurl* sets a string variable at initialization time to the value found from reading an URL.

## Syntax

```
Sdst strfromurl StringURL
```

## Initialization

*StringURL* -- string naming an URL.

*Sdst* -- destination string variable

## Examples

Here is an example of the strfromurl opcode. It uses the file *strfromurl.csd* [examples/strfromurl.csd].

### Example 878. Example of the strfromurl opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# strget

strget — Set string variable to value from strset table or string p-field

## Description

*strget* sets a string variable at initialization time to the value stored in *strset* table at the specified index, or a string p-field from the score. If there is no string defined for the index, the variable is set to an empty string.

## Syntax

```
Sdst strget indx
```

## Initialization

*indx* -- strset index, or score p-field

*Sdst* -- destination string variable

## Examples

Here is an example of the strget opcode. It uses the file *strget.csd* [examples/strget.csd].

### Example 879. Example of the strget opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# strset

strset — Allows a string to be linked with a numeric value.

## Description

Allows a string to be linked with a numeric value.

## Syntax

```
strset iarg, istring
```

## Initialization

*iarg* -- the numeric value.

*istring* -- the alphanumeric string (in double-quotes).

*strset* (optional) allows a string, such as a filename, to be linked with a numeric value. Its use is optional.

## Examples

The following statement, used in the orchestra header, will allow the numeric value 10 to be substituted anywhere the soundfile *asound.wav* is called for.

```
strset 10, "asound.wav"
```

## Examples

Here is an example of the strset opcode. It uses the file *strset.csd* [examples/strset.csd].

### Example 883. Example of the strset opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out    Audio in     No messages

# strsub

strsub — Extract a substring

## Description

Return a substring of the source string. strsub runs at init time only.

## Syntax

```
Sdst strsub Ssrc[, istart[, iend]]
```

## Initialization

*istart* (optional, defaults to 0) -- start position in Ssrc, counting from 0. A negative value means the end of the string.

*iend* (optional, defaults to -1) -- end position in Ssrc, counting from 0. A negative value means the end of the string. If *iend* is less than *istart*, the output is reversed.

## Examples

Here is an example of the strsub opcode. It uses the file *strsub.csd* [examples/strsub.csd].

### Example 884. Example of the strsub opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform

# strsubk

strsubk — Extract a substring

## Description

Return a substring of the source string. strsubk runs both at init and performance time.

## Syntax

```
Sdst strsubk Ssrc, kstart, kend
```

## Performance

*kstart* -- start position in Ssrc, counting from 0. A negative value means the end of the string.

*kend* -- end position in Ssrc, counting from 0. A negative value means the end of the string. If kend is less than kstart, the output is reversed.

## strtod

strtod — Converts a string to a float (i-rate).

## Description

Convert a string to a floating point value. It is also possible to pass an strset index or a string p-field from the score instead of a string argument. If the string cannot be parsed as a floating point or integer number, an init or perf error occurs and the instrument is deactivated.

## Syntax

```
ir strtod Sstr  
ir strtod indx
```

## Initialization

*Sstr* -- String to convert.

*indx* -- index of string set by strset

## Performance

*ir* -- Value of string as float.

## Credits

Author: Istvan Varga  
2005

# strtodk

strtodk — Converts a string to a float (k-rate).

## Description

Convert a string to a floating point value at i- or k-rate. It is also possible to pass an strset index or a string p-field from the score instead of a string argument. If the string cannot be parsed as a floating point or integer number, an init or perf error occurs and the instrument is deactivated.

### Note

If a k-rate index variable is used, it should be valid at i-time as well.

## Syntax

```
kr strtodk Sstr
```

```
kr strtodk kndx
```

## Performance

*kr* -- Value of string as float.

*Sstr* -- String to convert.

*indx* -- index of string set by strset

## Credits

Author: Istvan Varga  
2005

# strtol

strtol — Converts a string to a signed integer (i-rate).

## Description

Convert a string to a signed integer value. It is also possible to pass an strset index or a string p-field from the score instead of a string argument. If the string cannot be parsed as an integer number, an init error occurs and the instrument is deactivated.

## Syntax

```
ir strtol Sstr  
ir strtol indx
```

## Initialization

*Sstr* -- String to convert.

*indx* -- index of string set by strset

strtol can parse numbers in decimal, octal (prefixed by 0), and hexadecimal (with a prefix of 0x) format.

## Performance

*ir* -- Value of string as signed integer.

## Credits

Author: Istvan Varga  
2005

# strtolk

strtolk — Converts a string to a signed integer (k-rate).

## Description

Convert a string to a signed integer value at i- or k-rate. It is also possible to pass an strset index or a string p-field from the score instead of a string argument. If the string cannot be parsed as an integer number, an init or perf error occurs and the instrument is deactivated.

### Note

If a k-rate index variable is used, it should be valid at i-time as well.

## Syntax

```
kr strtolk Sstr
```

```
kr strtolk knidx
```

strtolk can parse numbers in decimal, octal (prefixed by 0), and hexadecimal (with a prefix of 0x) format.

## Performance

*kr* -- Value of string as signed integer.

*Sstr* -- String to convert.

*indx* -- index of string set by strset

## Credits

Author: Istvan Varga  
2005

# strupper

strupper — Convert a string to upper case

## Description

Convert Ssrc to upper case, and write the result to Sdst. strupper runs at init time only.

## Syntax

```
Sdst strupper Ssrc
```

## See also

# strupperk

strupperk — Convert a string to upper case

## Description

Convert Ssrc to upper case, and write the result to Sdst. strupperk runs both at init and performance time.

## Syntax

```
Sdst strupperk Ssrc
```

## See also

*strupper*

# subinstr

subinstr — Creates and runs a numbered instrument instance.

## Description

Creates an instance of another instrument and is used as if it were an opcode.

## Syntax

```
a1, [...] [, a8] subinstr instrnum [, p4] [, p5] [...]
```

```
a1, [...] [, a8] subinstr "insname" [, p4] [, p5] [...]
```

## Initialization

*instrnum* -- Number of the instrument to be called.

“*insname*” -- A string (in double-quotes) representing a named instrument.

## Performance

*a1, ..., a8* -- The audio output from the called instrument. This is generated using the *signal output* opcodes.

*p4, p5, ...* -- Additional input values the are mapped to the called instrument p-fields, starting with p4.

The called instrument's p2 and p3 values will be identical to the host instrument's values. While the host instrument can *control its own duration*, any such attempts inside the called instrument will most likely have no effect.

## See Also

*event, schedule, subinstrinit*

## Examples

Here is an example of the subinstr opcode. It uses the file *subinstr.csd* [examples/subinstr.csd].

### Example 885. Example of the subinstr opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# svfilter

**svfilter** — A resonant second order filter, with simultaneous lowpass, highpass and bandpass outputs.

## Description

Implementation of a resonant second order filter, with simultaneous lowpass, highpass and bandpass outputs.

## Syntax

```
alow, ahigh, aband svfilter asig, kcf, kq [, iscl] [, iskip]
```

## Initialization

*iscl* -- coded scaling factor, similar to that in *reson*. A non-zero value signifies a peak response factor of 1, i.e. all frequencies other than *kcf* are attenuated in accordance with the (normalized) response curve. A zero value signifies no scaling of the signal, leaving that to some later adjustment (see *balance*). The default value is 0.

*iskip* (optional, default=0) -- initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*svfilter* is a second order state-variable filter, with k-rate controls for cutoff frequency and Q. As Q is increased, a resonant peak forms around the cutoff frequency. *svfilter* has simultaneous lowpass, highpass, and bandpass filter outputs; by mixing the outputs together, a variety of frequency responses can be generated. The state-variable filter, or "multimode" filter was a common feature in early analog synthesizers, due to the wide variety of sounds available from the interaction between cutoff, resonance, and output mix ratios. *svfilter* is well suited to the emulation of "analog" sounds, as well as other applications where resonant filters are called for.

*kcf* -- Cutoff or resonant frequency of the filter, measured in Hz.

*kq* -- Q of the filter, which is defined (for bandpass filters) as bandwidth/cutoff. *kq* should be in a range between 1 and 500. As *kq* is increased, the resonance of the filter increases, which corresponds to an increase in the magnitude and "sharpness" of the resonant peak. When using *svfilter* without any scaling of the signal (where *iscl* is either absent or 0), the volume of the resonant peak increases as Q increases. For high values of Q, it is recommended that *iscl* be set to a non-zero value, or that an external scaling function such as *balance* is used.

*svfilter* is based upon an algorithm in Hal Chamberlin's *Musical Applications of Microprocessors* (Hayden Books, 1985).

## Examples

Here is an example of the svfilter opcode. It uses the file *svfilter.csd* [examples/svfilter.csd].

### Example 889. Example of the svfilter opcode.

# syncgrain

`syncgrain` — Synchronous granular synthesis.

## Description

`syncgrain` implements synchronous granular synthesis. The source sound for the grains is obtained by reading a function table containing the samples of the source waveform. For sampled-sound sources, `GEN01` is used. `syncgrain` will accept deferred allocation tables.

The grain generator has full control of frequency (grains/sec), overall amplitude, grain pitch (a sampling increment) and grain size (in secs), both as fixed or time-varying (signal) parameters. An extra parameter is the grain pointer speed (or rate), which controls which position the generator will start reading samples in the table for each successive grain. It is measured in fractions of grain size, so a value of 1 (the default) will make each successive grain read from where the previous grain should finish. A value of 0.5 will make the next grain start at the midway position from the previous grain start and finish, etc.. A value of 0 will make the generator read always from a fixed position of the table (wherever the pointer was last at). A negative value will decrement pointer positions. This control gives extra flexibility for creating timescale modifications in the resynthesis.

`syncgrain` will generate any number of parallel grain streams (which will depend on grain density/frequency), up to the `iolaps` value (default 100). The number of streams (overlapped grains) is determined by `grainsize*grain_freq`. More grain overlaps will demand more calculations and the synthesis might not run in realtime (depending on processor power).

`syncgrain` can simulate FOF-like formant synthesis, provided that a suitable shape is used as grain envelope and a sinewave as the grain wave. For this use, grain sizes of around 0.04 secs can be used. The formant centre frequency is determined by the grain pitch. Since this is a sampling increment, in order to use a frequency in Hz, that value has to be scaled by `tablesize/sr`. Grain frequency will determine the fundamental.

`syncgrain` uses floating-point indexing, so its precision is not affected by large-size tables. This opcode is based on the `SndObj` library `SyncGrain` class.

## Syntax

```
asig syncgrain kamp, kfreq, kpitch, kgrsize, kprate, ifun1, \
      ifun2, iolaps
```

## Initialization

`ifun1` -- source signal function table. Deferred-allocation tables (see `GEN01`) are accepted, but the opcode expects a mono source.

`ifun2` -- grain envelope function table.

`iolaps` -- maximum number of overlaps,  $\max(kfreq) * \max(kgrsize)$ . Estimating a large value should not affect performance, but exceeding this value will probably have disastrous consequences.

## Performance

`kamp` -- amplitude scaling

*kfreq* -- frequency of grain generation, or density, in grains/sec.

*kpitch* -- grain pitch scaling (1=normal pitch, < 1 lower, > 1 higher; negative, backwards)

*kgrsize* -- grain size in secs.

*kprate* -- readout pointer rate, in grains. The value of 1 will advance the reading pointer 1 grain ahead in the source table. Larger values will time-compress and smaller values will time-expand the source signal. Negative values will cause the pointer to run backwards and zero will freeze it.

## Examples

Here is an example of the syncgrain opcode. It uses the file *syncgrain.csd* [examples/syncgrain.csd].

### Example 890. Example of the syncgrain opcode.

# syncloop

`syncloop` — Synchronous granular synthesis.

## Description

`syncloop` is a variation on `syncgrain`, which implements synchronous granular synthesis. `syncloop` adds loop start and end points and an optional start position. Loop start and end control grain start positions, so the actual grains can go beyond the loop points (if the loop points are not at the extremes of the table), enabling seamless crossfading. For more information on the granular synthesis process, check the `syncgrain` manual page.

## Syntax

```
asig syncloop kamp, kfreq, kpitch, kgrsize, kprate, klstart, \
      klend, ifun1, ifun2, iolaps[, istart, iskip]
```

## Initialization

*ifun1* -- source signal function table. Deferred-allocation tables (see *GEN01*) are accepted, but the opcode expects a mono source.

*ifun2* -- grain envelope function table.

*iolaps* -- maximum number of overlaps,  $\max(kfreq) * \max(kgrsize)$ . Estimating a large value should not affect performance, but exceeding this value will probably have disastrous consequences.

*istart* -- starting point of synthesis in secs (defaults to 0).

*iskip* -- if 1, the opcode initialisation is skipped, for tied notes, performance continues from the position in the loop where the previous note stopped. The default, 0, does not skip initialisation

## Performance

*kamp* -- amplitude scaling

*kfreq* -- frequency of grain generation, or density, in grains/sec.

*kpitch* -- grain pitch scaling (1=normal pitch, < 1 lower, > 1 higher; negative, backwards)

*kgrsize* -- grain size in secs.

*kprate* -- readout pointer rate, in grains. The value of 1 will advance the reading pointer 1 grain ahead in the source table. Larger values will time-compress and smaller values will time-expand the source signal. Negative values will cause the pointer to run backwards and zero will freeze it.

*klstart* -- loop start in secs.

*klend* -- loop end in secs.

# syncphasor

`syncphasor` — Produces a normalized moving phase value with sync input and output.

## Description

Produces a moving phase value between zero and one and an extra impulse output ("sync out") whenever its phase value crosses or is reset to zero. The phase can be reset at any time by an impulse on the "sync in" parameter.

## Syntax

```
aphase, asyncout syncphasor xcps, asyncin, [, iphs]
```

## Initialization

*iphs* (optional) -- initial phase, expressed as a fraction of a cycle (0 to 1). A negative value will cause phase initialization to be skipped. The default value is zero.

## Performance

*aphase* -- the output phase value; always between 0 and 1.

*asyncout* -- the sync output has a value of 1.0 for one sample whenever the phase value crosses zero or whenever the sync input is non-zero. It is zero at all other times.

*asyncin* -- the sync input causes the phase to reset to zero whenever *asyncin* is non-zero.

*xcps* -- frequency of the phasor in cycles-per-second. If *xcps* is negative, the phase value will decrease from 1 to 0 instead of increasing.

An internal phase is successively accumulated in accordance with the *xcps* frequency to produce a moving phase value, normalized to lie in the range  $0 \leq \text{phs} < 1$ . When used as the index to a *table* unit, this phase (multiplied by the desired function table length) will cause it to behave like an oscillator.

The phase of *syncphasor* though can be synced to another phasor (or other signal) using the *asyncin* parameter. Any time that *asyncin* is a non-zero value, the value of *aphase* will be reset to zero. *syncphasor* also outputs its own "sync" signal that consists of a one-sample impulse whenever its phase crosses zero or is reset. This makes it easy to chain together multiple *syncphasor* opcodes to create an oscillator "hard sync" effect.

## Examples

Here is an example of the *syncphasor* opcode. It uses the file *syncphasor.csd* [examples/*syncphasor.csd*].

; http://en.wikipedia.org/wiki/Phase_distortion_synthesis

; Sawtooth Resonance waveform. Smoothing function is just the inverted
; master phasor.

; The Wikipedia article shows an inverted cosine as the stored waveform,
; which implies that it must be unipolar for the smoothing to work.
; I have substituted a sine wave in the first phrase to keep the output
; bipolar. The second phrase demonstrates the much "rezzier" sound of the
; bipolar cosine due to discontinuities.

# system

system — Call an external program via the system call

## Description

**system** and **system\_i** call any external command understood by the operating system, similarly to the C function `system()`. **system\_i** runs at i-time only, while **system** runs both at initialization and performance time.

## Syntax

```
ires system_i itrig, Scmd, [inowait]
```

```
kres system ktrig, Scmd, [knowait]
```

## Initialization

*Scmd* -- command string

*itrig* -- if greater than zero the opcode executes the command; otherwise it is a null operation.

## Performance

*ktrig* -- if greater than zero and different from the value on the previous control cycle the opcode executes the command. Initially this previous value is taken as zero.

*inowait,knowait* -- if given a non zero the command is run in the background and the command does not wait for the result. (default = 0)

*ires, kres* -- the return code of the command in wait mode and if the command is run. In other cases returns zero.

More than one system command (a script) can be executed with a single **system** opcode by using double braces strings `{}{}`.

### Note

This opcode is very system dependant, so should be used with extreme care (or not used) if platform neutrality is desired.

## Example

Here is an example of the **system\_i** opcode. It uses the file `system.csd` [examples/system.csd].

### Example 894. Example of the system opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# tb

tb0, tb1, tb2, tb3, tb4, tb5, tb6, tb7, tb8, tb9, tb10, tb11, tb12, tb13, tb14, tb15, tb0\_init, tb1\_init, tb2\_init, tb3\_init, tb4\_init, tb5\_init, tb6\_init, tb7\_init, tb8\_init, tb9\_init, tb10\_init, tb11\_init, tb12\_init, tb13\_init, tb14\_init, tb15\_init — Table Read Access inside expressions.

## Description

Allow to read tables in function fashion, to be used inside expressions. At present time Csound only supports functions with a single input argument. However, to access table elements, user must provide two numbers, i.e. the number of table and the index of element. So, in order to allow to access a table element with a function, a previous preparation step should be done.

## Syntax

```
tb0_init ifn  
  
tb1_init ifn  
  
tb2_init ifn  
  
tb3_init ifn  
  
tb4_init ifn  
  
tb5_init ifn  
  
tb6_init ifn  
  
tb7_init ifn  
  
tb8_init ifn  
  
tb9_init ifn  
  
tb10_init ifn  
  
tb11_init ifn  
  
tb12_init ifn  
  
tb13_init ifn  
  
tb14_init ifn  
  
tb15_init ifn  
  
iout = tb0(iIndex)  
kout = tb0(kIndex)
```

```
iout = tb1(iIndex)  
  
kout = tb1(kIndex)  
  
iout = tb2(iIndex)  
  
kout = tb2(kIndex)  
  
iout = tb3(iIndex)  
  
kout = tb3(kIndex)  
  
iout = tb4(iIndex)  
  
kout = tb4(kIndex)  
  
iout = tb5(iIndex)  
  
kout = tb5(kIndex)  
  
iout = tb6(iIndex)  
  
kout = tb6(kIndex)  
  
iout = tb7(iIndex)  
  
kout = tb7(kIndex)  
  
iout = tb8(iIndex)  
  
kout = tb8(kIndex)  
  
iout = tb9(iIndex)  
  
kout = tb9(kIndex)  
  
iout = tb10(iIndex)  
  
kout = tb10(kIndex)  
  
iout = tb11(iIndex)  
  
kout = tb11(kIndex)  
  
iout = tb12(iIndex)  
  
kout = tb12(kIndex)  
  
iout = tb13(iIndex)  
  
kout = tb13(kIndex)  
  
iout = tb14(iIndex)
```

```
kout = tb14(kIndex)

iout = tb15(iIndex)

kout = tb15(kIndex)
```

## Performance

There are 16 different opcodes whose name is associated with a number from 0 to 15. User can associate a specific table with each opcode (so the maximum number of tables that can be accessed in function fashion is 16). Prior to access a table, user must associate the table with one of the 16 opcodes by means of an opcode chosen among *tb0\_init*, ..., *tb15\_init*. For example,

```
tb0_init 1
```

associates table 1 with *tb0()* function, so that, each element of table 1 can be accessed (in function fashion) with:

```
kvar = tb0(k_some_index_of_table1) * k_some_other_var
```

```
iVar = tb0(i_some_index_of_table1) + i_some_other_var
```

etc...

By using these opcodes, user can drastically reduce the number of lines of an orchestra, improving its readability.

# tab

tab — Fast table opcodes.

## Description

Fast table opcodes. Faster than *table* and *tablew* because don't allow wrap-around and limit and don't check index validity. Have been implemented in order to provide fast access to arrays. Support non-power of two tables (can be generated by any GEN function by giving a negative length value).

## Syntax

```
ir tab_i indx, ifn[, ixmode]  
  
kr tab kndx, ifn[, ixmode]  
  
ar tab xndx, ifn[, ixmode]  
  
tabw_i isig, indx, ifn [,ixmode]  
  
tabw ksig, kndx, ifn [,ixmode]  
  
tabw asig, andx, ifn [,ixmode]
```

## Initialization

*ifn* -- table number

*ixmode* -- defaults to zero. If zero *xndx* and *ixoff* ranges match the length of the table; if non zero *xndx* and *ixoff* have a 0 to 1 range.

*isig* -- input value to write.

*indx* -- table index

## Performance

*asig, ksig* -- input signal to write.

*andx, kndx* -- table index.

*tab* and *tabw* opcodes are similar to *table* and *tablew*, but are faster and support tables having non-power-of-two length.

Special care of index value must be taken into account. Index values out of the table allocated space will crash Csound.

## Examples

Here is an example of the tab opcode. It uses the file *tab.csd* [examples/tab.csd].

### Example 895. Example of the tab opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# tabifd

tabifd — Instantaneous Frequency Distribution, magnitude and phase analysis.

## Description

The tabifd opcode takes an input function table and performs an Instantaneous Frequency, magnitude and phase analysis, using the STFT and tabifd (Instantaneous Frequency Distribution), as described in Lazzarini et al, "Time-stretching using the Instantaneous Frequency Distribution and Partial Tracking", Proc.of ICMC05, Barcelona. It generates two PV streaming signals, one containing the amplitudes and frequencies (a similar output to pvsanal) and another containing amplitudes and unwrapped phases.

## Syntax

```
ffr,fphs tabifd ktimpt, kamp, kpitch, ifftsize, ihopsize, iwintype,ifn
```

## Initialization

*ifftsize* -- FFT analysis size, must be power-of-two and integer multiple of the hopsize.

*ihopsize* -- hopsize in samples

*iwintype* -- window type (0: Hamming, 1: Hanning)

*ifn* -- source function table

## Performance

*ffr* -- output pv stream in AMP\_FREQ format

*fphs* -- output pv stream in AMP\_PHASE format

*ktimpt* -- time point (in secs) to read from table (if less than 0 or bigger than table length, it will wrap-around)

*kamp* -- amplitude scaling

*kpitch* -- pitch scaling (transposition)

## Examples

Here is an example of the tabifd opcode. It uses the file *tabifd.csd* [examples/tabifd.csd].

### Example 896. Example of the tabifd opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# table

table — Accesses table values by direct indexing.

## Description

Accesses table values by direct indexing.

## Syntax

```
ares table andx, ifn [, ixmode] [, ixoff] [, iwrap]  
  
ires table indx, ifn [, ixmode] [, ixoff] [, iwrap]  
  
kres table kndx, ifn [, ixmode] [, ixoff] [, iwrap]
```

## Initialization

*ifn* -- function table number.

*ixmode* (optional) -- index data mode. The default value is 0.

- 0 = raw index
- 1 = normalized (0 to 1)

*ixoff* (optional) -- amount by which index is to be offset. For a table with origin at center, use *tablesize/2* (raw) or *.5* (normalized). The default value is 0.

*iwrap* (optional) -- wraparound index flag. The default value is 0.

- 0 = nowrap (index < 0 treated as index=0; index > *tablesize* sticks at index=*size*)
- 1 = wraparound.

## Performance

*table* invokes table lookup on behalf of init, control or audio indices. These indices can be raw entry numbers (0,1,2...*size* - 1) or scaled values (0 to 1-e). Indices are first modified by the offset value then checked for range before table lookup (see *iwrap*). If index is likely to be full scale, or if interpolation is being used, the table should have an extended guard point. *table* indexed by a periodic phasor ( see *phasor*) will simulate an oscillator.

## Examples

Here is an example of the table opcode. It uses the file *table.csd* [examples/table.csd].

### Example 897. Example of the table opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## table3

table3 — Accesses table values by direct indexing with cubic interpolation.

### Description

Accesses table values by direct indexing with cubic interpolation.

### Syntax

```
ares table3 andx, ifn [, ixmode] [, ixoff] [, iwrap]  
  
ires table3 indx, ifn [, ixmode] [, ixoff] [, iwrap]  
  
kres table3 kndx, ifn [, ixmode] [, ixoff] [, iwrap]
```

### Initialization

*ifn* -- function table number.

*ixmode* (optional) -- index data mode. The default value is 0.

- 0 = raw index
- 1 = normalized (0 to 1)

*ixoff* (optional) -- amount by which index is to be offset. For a table with origin at center, use tablesiz/2 (raw) or .5 (normalized). The default value is 0.

*iwrap* (optional) -- wraparound index flag. The default value is 0.

- 0 = nowrap (index < 0 treated as index=0; index > tablesiz sticks at index=siz)
- 1 = wraparound.

### Performance

*table3* is identical to *tablei*, except that it uses cubic interpolation. (New in Csound version 3.50).

### See Also

*table*, *tablei*, *oscill*, *oscill2*, *osciln*

# tablecopy

tablecopy — Simple, fast table copy opcode.

## Description

Simple, fast table copy opcode.

## Syntax

```
tablecopy kdft, ksft
```

## Performance

*kdft* -- Destination function table.

*ksft* -- Number of source function table.

*tablecopy* -- Simple, fast table copy opcode. Takes the table length from the destination table, and reads from the start of the source table. For speed reasons, does not check the source length - just copies regardless - in "wrap" mode. This may read through the source table several times. A source table with length 1 will cause all values in the destination table to be written to its value.

*tablecopy* cannot read or write the guardpoint. To read it use *table*, with *ndx* = the table length. Likewise use table write to write it.

To write the guardpoint to the value in location 0, use *tablegpw*.

This is primarily to change function tables quickly in a real-time situation.

## Examples

Here is an example of the tablecopy opcode. It uses the file *tablecopy.csd* [examples/tablecopy.csd].

### Example 898. Example of the tablecopy opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# tablefilter

tablefilter — Filters a source table and writes result into a destination table.

## Description

This opcode can be used in order to filter values from function tables following certain algorithms. The filtered output is written into a destination table and the number of elements that have passed the filter is returned.

## Syntax

```
knumpassed tablefilter kouttable, kintatable, kmode, kparam
```

## Performance

*knumpassed* -- the number of elements that have passed the filter.

*kouttable* -- the number of the table containing the values that have passed.

*kintatable* -- the number of the table used as filter input.

*kmode* -- mode of the filter:

- 1 -- tests the weight of the denominators of the fractions in the source table. Letting pass only values from the source that are less heavy than the weight of the threshold.
- 2 -- tests the weight of the denominators of the fractions in the source table. Letting pass only values from the source that are heavier than or equal to the weight of the threshold.

*kparam* -- integer threshold parameter for the filter. It means that denominators whose weights are heavier than the weight of this threshold are not passed through the filter. The weight of an integer is calculated using Clarence Barlow's function of indigestibility of a number. According to this function, higher prime numbers contribute to an increased weight of any natural integer they divide. The order of the first 16 integers according to their indigestibility is: 1, 2, 4, 3, 8, 6, 16, 12, 9, 5, 10, 15, 7, 14.

## Examples

Here is an example of the tablefilter opcode. It uses the file *tablefilter.csd* [examples/tablefilter.csd].

### Example 899. Example of the tablefilter opcode.

# tablefilteri

tablefilteri — Filters a source table and writes result into a destination table.

## Description

This opcode can be used in order to filter values from function tables following certain algorithms. The filtered output is written into a destination table and the number of elements that have passed the filter is returned.

## Syntax

```
inumpassed tablefilteri iouttable, iintatble, imode, iparam
```

## Initialization

*inumpassed* -- the number of elements that have passed the filter.

*iouttable* -- the number of the table containing the values that have passed.

*iintatble* -- the number of the table used as filter input.

*imode* -- mode of the filter:

- 1 -- tests the weight of the denominators of the fractions in the source table. Letting pass only values from the source that are less heavy than the weight of the threshold.
- 2 -- tests the weight of the denominators of the fractions in the source table. Letting pass only values from the source that are heavier than or equal to the weight of the threshold.

*iparam* -- integer threshold parameter for the filter. It means that denominators whose weights are heavier than the weight of this threshold are not passed through the filter. The weight of an integer is calculated using Clarence Barlow's function of indigestibility of a number. According to this function, higher prime numbers contribute to an increased weight of any natural integer they divide. The order of the first 16 integers according to their indigestibility is: 1, 2, 4, 3, 8, 6, 16, 12, 9, 5, 10, 15, 7, 14.

## Examples

Here is an example of the tablefilteri opcode. It uses the file *tablefilter.csd* [examples/tablefilter.csd].

# tablegpw

tablegpw — Writes a table's guard point.

## Description

Writes a table's guard point.

## Syntax

```
tablegpw kfn
```

## Performance

*kfn* -- Table number to be interrogated

*tablegpw* -- For writing the table's guard point, with the value which is in location 0. Does nothing if table does not exist.

Likely to be useful after manipulating a table with *tablemix* or *tablecopy*.

## See Also

*tablecopy*, *tablemix*, *tableicopy*, *tableigpw*, *tableimix*

# tablei

tablei — Accesses table values by direct indexing with linear interpolation.

## Description

Accesses table values by direct indexing with linear interpolation.

## Syntax

```
ares tablei andx, ifn [, ixmode] [, ixoff] [, iwrap]  
  
ires tablei indx, ifn [, ixmode] [, ixoff] [, iwrap]  
  
kres tablei kndx, ifn [, ixmode] [, ixoff] [, iwrap]
```

## Initialization

*ifn* -- function table number. *tablei* requires the extended guard point.

*ixmode* (optional) -- index data mode. The default value is 0.

- 0 = raw index
- 1 = normalized (0 to 1)

*ixoff* (optional) -- amount by which index is to be offset. For a table with origin at center, use *tablesize*/2 (raw) or .5 (normalized). The default value is 0.

*iwrap* (optional) -- wraparound index flag. The default value is 0.

- 0 = nowrap (index < 0 treated as index=0; index > *tablesize* sticks at index=*size*)
- 1 = wraparound.

## Performance

*tablei* is a interpolating unit in which the fractional part of index is used to interpolate between adjacent table entries. The smoothness gained by interpolation is at some small cost in execution time (see also *oscili*, etc.), but the interpolating and non-interpolating units are otherwise interchangeable. Note that when *tablei* uses a periodic index whose modulo *n* is less than the power of 2 table length, the interpolation process requires that there be an (*n* + 1)th table value that is a repeat of the 1st (see *f Statement* in score).

## Examples

Here is an example of the tablei opcode. It uses the file *tablei.csd* [examples/tablei.csd].

**Example 901. Example of the tablei opcode.**

# tableicopy

tableicopy — Simple, fast table copy opcode.

## Description

Simple, fast table copy opcode.

## Syntax

```
tableicopy idft, isft
```

## Initialization

*idft* -- Destination function table.

*isft* -- Number of source function table.

## Performance

*tableicopy* -- Simple, fast table copy opcodes. Takes the table length from the destination table, and reads from the start of the source table. For speed reasons, does not check the source length - just copies regardless - in "wrap" mode. This may read through the source table several times. A source table with length 1 will cause all values in the destination table to be written to its value.

*tableicopy* cannot read or write the guardpoint. To read it use *table*, with *ndx* = the table length. Likewise use *table write* to write it.

To write the guardpoint to the value in location 0, use *tablegpw*.

This is primarily to change function tables quickly in a real-time situation.

# tableikt

tableikt — Provides k-rate control over table numbers.

## Description

k-rate control over table numbers. Function tables are read with linear interpolation.

The standard Csound opcode *tablei*, when producing a k- or a-rate result, can only use an init-time variable to select the table number. *tableikt* accepts k-rate control as well as i-time. In all other respects they are similar to the original opcodes.

## Syntax

```
ares tableikt xndx, kfn [, ixmode] [, ixoff] [, iwrap]  
kres tableikt kndx, kfn [, ixmode] [, ixoff] [, iwrap]
```

## Initialization

*ixmode* -- if 0, *xndx* and *ixoff* ranges match the length of the table. if non-zero *xndx* and *ixoff* have a 0 to 1 range. Default is 0

*ixoff* -- if 0, total index is controlled directly by *xndx*, ie. the indexing starts from the start of the table. If non-zero, start indexing from somewhere else in the table. Value must be positive and less than the table length (*ixmode* = 0) or less than 1 (*ixmode* not equal to 0). Default is 0.

*iwrap* -- if *iwrap* = 0, *Limit mode*: when total index is below 0, then final index is 0. Total index above table length results in a final index of the table length - high out of range total indexes stick at the upper limit of the table. If *iwrap* not equal to 0, *Wrap mode*: total index is wrapped modulo the table length so that all total indexes map into the table. For instance, in a table of length 8, *xndx* = 5 and *ixoff* = 6 gives a total index of 11, which wraps to a final index of 3. Default is 0.

## Performance

*kndx* -- Index into table, either a positive number range matching the table length (*ixmode* = 0) or a 0 to 1 range (*ixmode* not equal to 0).

*xndx* -- matching the table length (*ixmode* = 0) or a 0 to 1 range (*ixmode* not equal to 0)

*kfn* -- Table number. Must be  $\geq 1$ . Floats are rounded down to an integer. If a table number does not point to a valid table, or the table has not yet been loaded (*GEN01*) then an error will result and the instrument will be de-activated.

### Caution with k-rate table numbers

At k-rate, if a table number of  $< 1$  is given, or the table number points to a non-existent table, or to one which has a length of 0 (it is to be loaded from a file later) then an error will result and the instrument will be deactivated. *kfn* must be initialized at the appropriate rate using *init*. Attempting to load an i-rate value into *kfn* will result in an error.

# Examples

Here is an example of the tableikt opcode. It uses the file *tableikt.csd* [examples/tableikt.csd].

# tableimix

tableimix — Mixes two tables.

## Description

Mixes two tables.

## Syntax

```
tableimix idft, idoff, ilen, is1ft, is1off, is1g, is2ft, is2off, is2g
```

## Initialization

*idft* -- Destination function table.

*idoff* -- Offset to start writing from. Can be negative.

*ilen* -- Number of write operations to perform. Negative means work backwards.

*is1ft*, *is2ft* -- Source function tables. These can be the same as the destination table, if care is exercised about direction of copying data.

*is1off*, *is2off* -- Offsets to start reading from in source tables.

*is1g*, *is2g* -- Gains to apply when reading from the source tables. The results are added and the sum is written to the destination table.

## Performance

*tableimix* -- This opcode mixes from two tables, with separate gains into the destination table. Writing is done for *ilen* locations, usually stepping forward through the table - if *ilen* is positive. If it is negative, then the writing and reading order is backwards - towards lower indexes in the tables. This bi-directional option makes it easy to shift the contents of a table sideways by reading from it and writing back to it with a different offset.

If *ilen* is 0, no writing occurs. Note that the internal integer value of *ilen* is derived from the ANSI C floor() function - which returns the next most negative integer. Hence a fractional negative *ilen* value of -2.3 would create an internal length of 3, and cause the copying to start from the offset locations and proceed for two locations to the left.

The total index for table reading and writing is calculated from the starting offset for each table, plus the index value, which starts at 0 and then increments (or decrements) by 1 as mixing proceeds.

These total indexes can potentially be very large, since there is no restriction on the offset or the *ilen*. However each total index for each table is ANDed with a length mask (such as 0000 0111 for a table of length 8) to form a final index which is actually used for reading or writing. So no reading or writing can occur outside the tables. This is the same as "wrap" mode in table read and write. These opcodes do not read or write the guardpoint. If a table has been rewritten with one of these, then if it has a guardpoint which is supposed to contain the same value as the location 0, then call *tableigpw* afterwards.

The indexes and offsets are all in table steps - they are not normalized to 0 - 1. So for a table of length 256, *ilen* should be set to 256 if all the table was to be read or written.

The tables do not need to be the same length - wrapping occurs individually for each table.

## Examples

Here is an example of the tableimix opcode. It uses the file *tableimix.csd* [examples/tableimix.csd].

# tableiw

tableiw — Change the contents of existing function tables.

## Description

This opcode operates on existing function tables, changing their contents. *tableiw* is used when all inputs are init time variables or constants and you only want to run it at the initialization of the instrument. The valid combinations of variable types are shown by the first letter of the variable names.

## Syntax

```
tableiw isig, indx, ifn [, ixmode] [, ixoff] [, iwgmode]
```

## Initialization

*isig* -- Input value to write to the table.

*indx* -- Index into table, either a positive number range matching the table length (*ixmode* = 0) or a 0 to 1 range (*ixmode* not equal to 0)

*ifn* -- Table number. Must be  $\geq 1$ . Floats are rounded down to an integer. If a table number does not point to a valid table, or the table has not yet been loaded (*GEN01*) then an error will result and the instrument will be de-activated.

*ixmode* (optional, default=0) -- index mode.

- 0 = *indx* and *ixoff* ranges match the length of the table.
- not equal to 0 = *indx* and *ixoff* have a 0 to 1 range.

*ixoff* (optional, default=0) -- index offset.

- 0 = Total index is controlled directly by *indx*, i.e. the indexing starts from the start of the table.
- Not equal to 0 = Start indexing from somewhere else in the table. Value must be positive and less than the table length (*ixmode* = 0) or less than 1 (*ixmode* not equal to 0).

*iwgmode* (optional, default=0) -- Wrap and guard point mode.

- 0 = Limit mode.
- 1 = Wrap mode.
- 2 = Guardpoint mode.

## Performance

## Limit mode (0)

Limit the total index ( $indx + iwoff$ ) to between 0 and the guard point. For a table of length 5, this means that locations 0 to 3 and location 4 (the guard point) can be written. A negative total index writes to location 0.

## Wrap mode (1)

Wrap total index value into locations 0 to E, where E is either one less than the table length or the factor of 2 number which is one less than the table length. For example, wrap into a 0 to 3 range - so that total index 6 writes to location 2.

## Guardpoint mode (2)

The guardpoint is written at the same time as location 0 is written - with the same value.

This facilitates writing to tables which are intended to be read with interpolation for producing smooth cyclic waveforms. In addition, before it is used, the total index is incremented by half the range between one location and the next, before being rounded down to the integer address of a table location.

Normally ( $igemode = 0$  or  $1$ ) for a table of length 5 - which has locations 0 to 3 as the main table and location 4 as the guard point, a total index in the range of 0 to 0.999 will write to location 0. ("0.999" means just less than 1.0.) 1.0 to 1.999 will write to location 1 etc. A similar pattern holds for all total indexes 0 to 4.999 ( $igemode = 0$ ) or to 3.999 ( $igemode = 1$ ).  $igemode = 0$  enables locations 0 to 4 to be written - with the guardpoint (4) being written with a potentially different value from location 0.

With a table of length 5 and the  $igemode = 2$ , then when the total index is in the range 0 to 0.499, it will write to locations 0 and 4. Range 0.5 to 1.499 will write to location 1 etc. 3.5 to 4.0 will also write to locations 0 and 4.

This way, the writing operation most closely approximates the results of interpolated reading. Guard point mode should only be used with tables that have a guardpoint.

Guardpoint mode is accomplished by adding 0.5 to the total index, rounding to the next lowest integer, wrapping it modulo the factor of two which is one less than the table length, writing the table (locations 0 to 3 in our example) and then writing to the guard point if index = 0.

## Examples

Here is an example of the tableiw opcode. It uses the file *tableiw.csd* [examples/tableiw.csd].

### Example 904. Example of the tableiw opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# tablekt

tablekt — Provides k-rate control over table numbers.

## Description

k-rate control over table numbers.

The standard Csound opcode *table* when producing a k- or a-rate result, can only use an init-time variable to select the table number. *tablekt* accepts k-rate control as well as i-time. In all other respects they are similar to the original opcodes.

## Syntax

```
ares tablekt xndx, kfn [, ixmode] [, ixoff] [, iwrap]  
kres tablekt kndx, kfn [, ixmode] [, ixoff] [, iwrap]
```

## Initialization

*ixmode* -- if 0, *xndx* and *ixoff* ranges match the length of the table. if non-zero *xndx* and *ixoff* have a 0 to 1 range. Default is 0

*ixoff* -- if 0, total index is controlled directly by *xndx*, ie. the indexing starts from the start of the table. If non-zero, start indexing from somewhere else in the table. Value must be positive and less than the table length (*ixmode* = 0) or less than 1 (*ixmode* not equal to 0). Default is 0.

*iwrap* -- if *iwrap* = 0, *Limit mode*: when total index is below 0, then final index is 0. Total index above table length results in a final index of the table length - high out of range total indexes stick at the upper limit of the table. If *iwrap* not equal to 0, *Wrap mode*: total index is wrapped modulo the table length so that all total indexes map into the table. For instance, in a table of length 8, *xndx* = 5 and *ixoff* = 6 gives a total index of 11, which wraps to a final index of 3. Default is 0.

## Performance

*kndx* -- Index into table, either a positive number range matching the table length (*ixmode* = 0) or a 0 to 1 range (*ixmode* not equal to 0).

*xndx* -- matching the table length (*ixmode* = 0) or a 0 to 1 range (*ixmode* not equal to 0)

*kfn* -- Table number. Must be  $\geq 1$ . Floats are rounded down to an integer. If a table number does not point to a valid table, or the table has not yet been loaded (*GEN01*) then an error will result and the instrument will be de-activated.

### Caution with k-rate table numbers

At k-rate, if a table number of  $< 1$  is given, or the table number points to a non-existent table, or to one which has a length of 0 (it is to be loaded from a file later) then an error will result and the instrument will be deactivated. *kfn* must be initialized at the appropriate rate using *init*. Attempting to load an i-rate value into *kfn* will result in an error.

## Examples

Here is an example of the tablekt opcode. It uses the file *tablekt.css* [examples/tablekt.css].

### **Example 905. Example of the tablekt opcode.**

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

Its output should include lines like these:

|     |         |
|-----|---------|
| i1  | 2.00000 |
| i1  | 1.00000 |
| i1  | 2.00000 |
| i1  | 1.00000 |
| ... |         |

# tablemix

tablemix — Mixes two tables.

## Description

Mixes two tables.

## Syntax

```
tablemix kdft, kdoff, klen, ks1ft, ksloff, ks1g, ks2ft, ks2off, ks2g
```

## Performance

*kdft* -- Destination function table.

*kdoff* -- Offset to start writing from. Can be negative.

*klen* -- Number of write operations to perform. Negative means work backwards.

*ks1ft*, *ks2ft* -- Source function tables. These can be the same as the destination table, if care is exercised about direction of copying data.

*ksloff*, *ks2off* -- Offsets to start reading from in source tables.

*ks1g*, *ks2g* -- Gains to apply when reading from the source tables. The results are added and the sum is written to the destination table.

*tablemix* -- This opcode mixes from two tables, with separate gains into the destination table. Writing is done for *klen* locations, usually stepping forward through the table - if *klen* is positive. If it is negative, then the writing and reading order is backwards - towards lower indexes in the tables. This bi-directional option makes it easy to shift the contents of a table sideways by reading from it and writing back to it with a different offset.

If *klen* is 0, no writing occurs. Note that the internal integer value of *klen* is derived from the ANSI C floor() function - which returns the next most negative integer. Hence a fractional negative *klen* value of -2.3 would create an internal length of 3, and cause the copying to start from the offset locations and proceed for two locations to the left.

The total index for table reading and writing is calculated from the starting offset for each table, plus the index value, which starts at 0 and then increments (or decrements) by 1 as mixing proceeds.

These total indexes can potentially be very large, since there is no restriction on the offset or the *klen*. However each total index for each table is ANDed with a length mask (such as 0000 0111 for a table of length 8) to form a final index which is actually used for reading or writing. So no reading or writing can occur outside the tables. This is the same as "wrap" mode in table read and write. These opcodes do not read or write the guardpoint. If a table has been rewritten with one of these, then if it has a guardpoint which is supposed to contain the same value as the location 0, then call *tablegpw* afterwards.

The indexes and offsets are all in table steps - they are not normalized to 0 - 1. So for a table of length 256, *klen* should be set to 256 if all the table was to be read or written.

The tables do not need to be the same length - wrapping occurs individually for each table.

## Examples

Here is an example of the tablemix opcode. It uses the file *tablemix.csd* [examples/tablemix.csd].

### Example 906. Example of the tablemix opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# tableng

tableng — Interrogates a function table for length.

## Description

Interrogates a function table for length.

## Syntax

```
iros tableng ifn  
  
kres tableng kfn
```

## Initialization

*ifn* -- Table number to be interrogated

## Performance

*kfn* -- Table number to be interrogated

*tableng* returns the length of the specified table. This will be a power of two number in most circumstances. It will not show whether a table has a guardpoint or not. It seems this information is not available in the table's data structure. If the specified table is not found, then 0 will be returned.

Likely to be useful for setting up code for table manipulation operations, such as *tablemix* and *tablecopy*.

## Examples

Here is an example of the *tableng* opcode. It uses the file *tableng.csd* [examples

### Example 907. Example of the tableng opcode.

# tablera

tablera — Reads tables in sequential locations.

## Description

These opcode reads tables in sequential locations to an a-rate variable. Some thought is required before using it. It has at least two major, and quite different, applications which are discussed below.

## Syntax

```
ares tablera kfn, kstart, koff
```

## Performance

*ares* -- a-rate destination for reading *ksmps* values from a table.

*kfn* -- i- or k-rate number of the table to read or write.

*kstart* -- Where in table to read or write.

*koff* -- i- or k-rate offset into table. Range unlimited - see explanation at end of this section.

In one application, *tablera* is intended to be used in pair with *tablewa*, or with several *tablera* opcodes before a *tablewa* -- all sharing the same *kstart* variable.

These read from and write to sequential locations in a table at audio rates, with *ksmps* floats being written and read each cycle.

*tablera* starts reading from location *kstart*. *tablewa* starts writing to location *kstart*, and then writes to *kstart* with the number of the location one more than the one it last wrote. (Note that for *tablewa*, *kstart* is both an input and output variable.) If the writing index reaches the end of the table, then no further writing occurs and zero is written to *kstart*.

For instance, if the table's length was 16 (locations 0 to 15), and *ksmps* was 5. Then the following steps would occur with repetitive runs of the *tablewa* opcode, assuming that *kstart* started at 0.

| Run Number | Initial <i>kstart</i> | Final <i>kstart</i> | Locations Written |
|------------|-----------------------|---------------------|-------------------|
| 1          | 0                     | 5                   | 0 1 2 3 4         |
| 2          | 5                     | 10                  | 5 6 7 8 9         |
| 3          | 10                    | 15                  | 10 11 12 13 14    |
| 4          | 15                    | 0                   | 15                |

This is to facilitate processing table data using standard a-rate orchestra code between the *tablera* and *tablewa* opcodes. They allow all Csound k-rate operators to be used (with caution) on a-rate variables - something that would only be possible otherwise by *ksmps* = 1, *downsamp* and *upsamp*.

### Several cautions

- The k-rate code in the processing loop is really running at a-rate, so time dependent functions like *port* and *oscil* work faster than normal - their code is expecting to be running at k-rate.
- This system will produce undesirable results unless the *ksmps* fits within the table length. For instance a table of length 16 will accommodate 1 to 16 samples, so this example will work with *ksmps* = 1 to 16.

Both these opcodes generate an error and deactivate the instrument if a table with length < *ksmps* is selected. Likewise an error occurs if *kstart* is below 0 or greater than the highest entry in the table - if *kstart* = table length.

- *kstart* is intended to contain integer values between 0 and (table length - 1). Fractional values above this should not affect operation but do not achieve anything useful.
- These opcodes are not interpolating, and the *kstart* and *koff* parameters always have a range of 0 to (table length - 1) - not 0 to 1 as is available in other table read/write opcodes. *koff* can be outside this range but it is wrapped around by the final AND operation.
- These opcodes are permanently in wrap mode. When *koff* is 0, no wrapping needs to occur, since the *kstart++* index will always be within the table's normal range. *koff* not equal to 0 can lead to wrapping.
- The offset does not affect the number of read/write cycles performed, or the value written to *kstart* by *tablewa*.
- These opcodes cannot read or write the guardpoint. Use *tablegpw* to write the guardpoint after manipulations have been done with *tablewa*.

## Examples

```
kstart = 0

lab1:
    atemp tablera ktabsource, kstart, 0 ; Read 5 values from table into an
                                              ; a-rate variable.

    atemp = log(atemp) ; Process the values using a-rate
                       ; code.

    kstart tablewa ktabdest, atemp, 0 ; Write it back to the table

if ktemp 0 goto lab1 ; Loop until all table locations
                      ; have been processed.
```

The above example shows a processing loop, which runs every k-cycle, reading each location in the table *ktabsource*, and writing the log of those values into the same locations of table *ktabdest*.

This enables whole tables, parts of tables (with offsets and different control loops) and data from several tables at once to be manipulated with a-rate code and written back to another (or to the same) table. This is a bit of a fudge, but it is faster than doing it with k-rate table read and write code.

Another application is:

```
kzero = 0
kloop = 0

kzero tablewa 23, asignal, 0 ; ksmps a-rate samples written
; into locations 0 to (ksmps -1) of table 23.

lab1: ktemp table kloop, 23 ; Start a loop which runs ksmps times,
; in which each cycle processes one of
[ Some code to manipulate ] ; table 23's values with k-rate orchestra
[ the value of ktemp. ] ; code.

tablew ktemp, kloop, 23 ; Write the processed value to the table.

kloop = kloop + 1 ; Increment the kloop, which is both the
; pointer into the table and the loop
if kloop < ksmps goto lab1 ; counter. Keep looping until all values
; in the table have been processed.

asignal tablera 23, 0, 0 ; Copy the table contents back
; to an a-rate variable.
```

*koff* -- This is an offset which is added to the sum of *kstart* and the internal index variable which steps through the table. The result is then ANDed with the lengthmask (000 0111 for a table of length 8 - or 9 with guardpoint) and that final index is used to read or write to the table. *koff* can be any value. It is converted into a long using the ANSI floor() function so that -4.3 becomes -5. This is what we would want when using offsets which range above and below zero.

Ideally this would be an optional variable, defaulting to 0, however with the existing Csound orchestra read code, such default parameters must be init time only. We want k-rate here, so we cannot have a default.

# tableseg

tableseg — Creates a new function table by making linear segments between values in stored function tables.

## Description

*tableseg* is like *linseg* but interpolate between values in a stored function tables. The result is a new function table passed internally to any following *vpvoc* which occurs before a subsequent *tableseg* (much like *lpread/lpreson* pairs work). The uses of these are described below under *vpvoc*.

## Syntax

```
tableseg ifn1, idur1, ifn2 [, idur2] [, ifn3] [...]
```

## Initialization

*ifn1*, *ifn2*, *ifn3*, etc. -- function table numbers. *ifn1*, *ifn2*, and so on, must be the same size.

*idur1*, *idur2*, etc. -- durations during which interpolation from one table to the next will take place.

## Examples

Here is an example of the *tableseg* opcode. It uses the file *tableseg.csd* [examples/tableseg.csd].

### Example 908. Example of the tableseg opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# tableshuffle

tableshuffle — shuffles the content of a function table so that each element of the source table is put into a different random position.

## Description

This opcode can be used in order to shuffle the content of function tables into a random order but without loosing any of the elements. Imagine shuffling a deck of cards. Each element of the table is copied to a different random position. If that position was already chosen before then the next free position is chosen. The length of the table remains the same.

## Syntax

```
tableshuffle ktablenum  
  
tableshufflei itablenum
```

## Performance

*ktablenum* or *itablenum* -- the number of the table to shuffle.

## Examples

Here is an example of the tableshuffle opcode. It uses the file *farey7shuffled.csd* [examples/farey7shuffled.csd].

### Example 909. Example of the tableshuffle opcode.

# tablew

tablew — Change the contents of existing function tables.

## Description

This opcode operates on existing function tables, changing their contents. *tablew* is for writing at k- or at a-rates, with the table number being specified at init time. Using *tablew* with i-rate signal and index values is allowed, but the specified data will always be written to the function table at k-rate, not during the initialization pass. The valid combinations of variable types are shown by the first letter of the variable names.

## Syntax

```
tablew asig, andx, ifn [, ixmode] [, ixoff] [, iwgmode]
```

```
tablew isig, indx, ifn [, ixmode] [, ixoff] [, iwgmode]
```

```
tablew ksig, kndx, ifn [, ixmode] [, ixoff] [, iwgmode]
```

## Initialization

*asig, isig, ksig* -- The value to be written into the table.

*andx, indx, kndx* -- Index into table, either a positive number range matching the table length (*ixmode* = 0) or a 0 to 1 range (*ixmode* != 0)

*ifn* -- Table number. Must be  $\geq 1$ . Floats are rounded down to an integer. If a table number does not point to a valid table, or the table has not yet been loaded (*GEN01*) then an error will result and the instrument will be de-activated.

*ixmode* (optional, default=0) -- index mode.

- 0 = *xndx* and *ixoff* ranges match the length of the table.
- !=0 = *xndx* and *ixoff* have a 0 to 1 range.

*ixoff* (optional, default=0) -- index offset.

- 0 = Total index is controlled directly by *xndx*, i.e. the indexing starts from the start of the table.
- !=0 = Start indexing from somewhere else in the table. Value must be positive and less than the table length (*ixmode* = 0) or less than 1 (*ixmode* != 0).

*iwgmode* (optional, default=0) -- Wrap and guardpoint mode.

- 0 = Limit mode.
- 1 = Wrap mode.

- 2 = Guardpoint mode.

## Performance

### Limit mode (0)

Limit the total index ( $ndx + iwoff$ ) to between 0 and the guard point. For a table of length 5, this means that locations 0 to 3 and location 4 (the guard point) can be written. A negative total index writes to location 0.

### Wrap mode (1)

Wrap total index value into locations 0 to E, where E is either one less than the table length or the factor of 2 number which is one less than the table length. For example, wrap into a 0 to 3 range - so that total index 6 writes to location 2.

### Guardpoint mode (2)

The guardpoint is written at the same time as location 0 is written - with the same value.

This facilitates writing to tables which are intended to be read with interpolation for producing smooth cyclic waveforms. In addition, before it is used, the total index is incremented by half the range between one location and the next, before being rounded down to the integer address of a table location.

Normally ( $igwmode = 0$  or  $1$ ) for a table of length 5 - which has locations 0 to 3 as the main table and location 4 as the guard point, a total index in the range of 0 to 0.999 will write to location 0. ("0.999" means just less than 1.0.) 1.0 to 1.999 will write to location 1 etc. A similar pattern holds for all total indexes 0 to 4.999 ( $igwmode = 0$ ) or to 3.999 ( $igwmode = 1$ ).  $igwmode = 0$  enables locations 0 to 4 to be written - with the guardpoint (4) being written with a potentially different value from location 0.

With a table of length 5 and the  $iwgmode = 2$ , then when the total index is in the range 0 to 0.499, it will write to locations 0 and 4. Range 0.5 to 1.499 will write to location 1 etc. 3.5 to 4.0 will also write to locations 0 and 4.

This way, the writing operation most closely approximates the results of interpolated reading. Guard point mode should only be used with tables that have a guardpoint.

Guardpoint mode is accomplished by adding 0.5 to the total index, rounding to the next lowest integer, wrapping it modulo the factor of two which is one less than the table length, writing the table (locations 0 to 3 in our example) and then writing to the guard point if index = 0.

*tablew* has no output value. The last three parameters are optional and have default values of 0.

## Caution with k-rate table numbers

At k-rate or a-rate, if a table number of < 1 is given, or the table number points to a non-existent table, or to one which has a length of 0 (it is to be loaded from a file later) then an error will result and the instrument will be deactivated. *kfn* and *afn* must be initialized at the appropriate rate using *init*. Attempting to load an i-rate value into *kfn* or *afn* will result in an error.

### Warning

Note that *tablew* is always a k-rate opcode. This means that even its i-rate version runs at k-rate and will write the value of the i-rate variable. For this reason, the following code will not work as expected:

```
<CsoundSynthesizer>
<CsOptions>
</CsOptions>
<CsInstruments>
giFt ftgen 1, 0, 8, 2, 0
instr 1
indx = 0
    tablew 10, indx, giFt
    ival tab_i indx, giFt
    print ival
endin
</CsInstruments>
<CsScore>
i 1 0 1
</CsScore>
</CsoundSynthesizer>
```

Although it may seem this program should print a 10 to the console. It will print 0, because *tab\_i* will read the value at the initialization of the note, before the first performance pass, when *tablew* writes its value.

# tablewa

tablewa — Writes tables in sequential locations.

## Description

This opcode writes to a table in sequential locations to and from an a-rate variable. Some thought is required before using it. It has at least two major, and quite different, applications which are discussed below.

## Syntax

```
kstart tablewa kfn, asig, koff
```

## Performance

*kstart* -- Where in table to read or write.

*kfn* -- i- or k-rate number of the table to read or write.

*asig* -- a-rate signal to read from when writing to the table.

*koff* -- i- or k-rate offset into table. Range unlimited - see explanation at end of this section.

In one application, it is intended to be used with one or with several *tablera* opcodes before a *tablewa* -- all sharing the same *kstart* variable.

These read from and write to sequential locations in a table at audio rates, with *ksmps* floats being written and read each cycle.

*tablera* starts reading from location *kstart*. *tablewa* starts writing to location *kstart*, and then writes to *kstart* with the number of the location one more than the one it last wrote. (Note that for *tablewa*, *kstart* is both an input and output variable.) If the writing index reaches the end of the table, then no further writing occurs and zero is written to *kstart*.

For instance, if the table's length was 16 (locations 0 to 15), and *ksmps* was 5. Then the following steps would occur with repetitive runs of the *tablewa* opcode, assuming that *kstart* started at 0.

| Run Number | Initial <i>kstart</i> | Final <i>kstart</i> | Locations Written |
|------------|-----------------------|---------------------|-------------------|
| 1          | 0                     | 5                   | 0 1 2 3 4         |
| 2          | 5                     | 10                  | 5 6 7 8 9         |
| 3          | 10                    | 15                  | 10 11 12 13 14    |
| 4          | 15                    | 0                   | 15                |

This is to facilitate processing table data using standard a-rate orchestra code between the *tablera* and *tablewa* opcodes. They allow all Csound k-rate operators to be used (with caution) on a-rate variables - something that would only be possible otherwise by *ksmps* = 1, *downsamp* and *upsamp*.

### Several cautions

- The k-rate code in the processing loop is really running at a-rate, so time dependent functions like *port* and *oscil* work faster than normal - their code is expecting to be running at k-rate.
- This system will produce undesirable results unless the *ksmps* fits within the table length. For instance a table of length 16 will accommodate 1 to 16 samples, so this example will work with *ksmps* = 1 to 16.

Both these opcodes generate an error and deactivate the instrument if a table with length < *ksmps* is selected. Likewise an error occurs if *kstart* is below 0 or greater than the highest entry in the table - if *kstart* = table length.

- *kstart* is intended to contain integer values between 0 and (table length - 1). Fractional values above this should not affect operation but do not achieve anything useful.
- These opcodes are not interpolating, and the *kstart* and *koff* parameters always have a range of 0 to (table length - 1) - not 0 to 1 as is available in other table read/write opcodes. *koff* can be outside this range but it is wrapped around by the final AND operation.
- These opcodes are permanently in wrap mode. When *koff* is 0, no wrapping needs to occur, since the *kstart++* index will always be within the table's normal range. *koff* not equal to 0 can lead to wrapping.
- The offset does not affect the number of read/write cycles performed, or the value written to *kstart* by *tablewa*.
- These opcodes cannot read or write the guardpoint. Use *tablegpw* to write the guardpoint after manipulations have been done with *tablewa*.

## Examples

```
kstart = 0

lab1:
    atemp tablera ktabsource, kstart, 0 ; Read 5 values from table into an
                                         ; a-rate variable.

    atemp = log(atemp) ; Process the values using a-rate
                         ; code.

    kstart tablewa ktabdest, atemp, 0 ; Write it back to the table

if ktemp 0 goto lab1 ; Loop until all table locations
                         ; have been processed.
```

The above example shows a processing loop, which runs every k-cycle, reading each location in the table *ktabsource*, and writing the log of those values into the same locations of table *ktabdest*.

This enables whole tables, parts of tables (with offsets and different control loops) and data from several tables at once to be manipulated with a-rate code and written back to another (or to the same) table. This is a bit of a fudge, but it is faster than doing it with k-rate table read and write code.

Another application is:

```
kzero = 0
kloop = 0

kzero tablewa 23, asignal, 0 ; ksmps a-rate samples written
; into locations 0 to (ksmps -1) of table 23.

lab1: ktemp table kloop, 23 ; Start a loop which runs ksmps times,
; in which each cycle processes one of
[ Some code to manipulate ] ; table 23's values with k-rate orchestra
[ the value of ktemp. ] ; code.

tablew ktemp, kloop, 23 ; Write the processed value to the table.

kloop = kloop + 1 ; Increment the kloop, which is both the
; pointer into the table and the loop
if kloop < ksmps goto lab1 ; counter. Keep looping until all values
; in the table have been processed.

asignal tablera 23, 0, 0 ; Copy the table contents back
; to an a-rate variable.
```

*koff* -- This is an offset which is added to the sum of *kstart* and the internal index variable which steps through the table. The result is then ANDed with the lengthmask (000 0111 for a table of length 8 - or 9 with guardpoint) and that final index is used to read or write to the table. *koff* can be any value. It is converted into a long using the ANSI floor() function so that -4.3 becomes -5. This is what we would want when using offsets which range above and below zero.

Ideally this would be an optional variable, defaulting to 0, however with the existing Csound orchestra read code, such default parameters must be init time only. We want k-rate here, so we cannot have a default.

# tablewkt

tablewkt — Change the contents of existing function tables.

## Description

This opcode operates on existing function tables, changing their contents. *tablewkt* uses a k-rate variable for selecting the table number. The valid combinations of variable types are shown by the first letter of the variable names.

## Syntax

```
tablewkt asig, andx, kfn [, ixmode] [, ixoff] [, iwgmode]
```

```
tablewkt ksig, kndx, kfn [, ixmode] [, ixoff] [, iwgmode]
```

## Initialization

*asig, ksig* -- The value to be written into the table.

*andx, kndx* -- Index into table, either a positive number range matching the table length (*ixmode* = 0) or a 0 to 1 range (*ixmode* != 0)

*kfn* -- Table number. Must be  $\geq 1$ . Floats are rounded down to an integer. If a table number does not point to a valid table, or the table has not yet been loaded (*GEN0I*) then an error will result and the instrument will be de-activated.

*ixmode* -- index mode. Default is zero.

- 0 = *xndx* and *ixoff* ranges match the length of the table.
- Not equal to 0 = *xndx* and *ixoff* have a 0 to 1 range.

*ixoff* -- index offset. Default is 0.

- 0 = Total index is controlled directly by *xndx*, i.e. the indexing starts from the start of the table.
- Not equal to 0 = Start indexing from somewhere else in the table. Value must be positive and less than the table length (*ixmode* = 0) or less than 1 (*ixmode* != 0).

*iwgmode* -- table writing mode. Default is 0.

- 0 = Limit mode.
- 1 = Wrap mode.
- 2 = Guardpoint mode.

# Performance

## Limit mode (0)

Limit the total index ( $ndx + iwoff$ ) to between 0 and the guard point. For a table of length 5, this means that locations 0 to 3 and location 4 (the guard point) can be written. A negative total index writes to location 0.

## Wrap mode (1)

Wrap total index value into locations 0 to E, where E is one less than either the table length or the factor of 2 number which is one less than the table length. For example, wrap into a 0 to 3 range - so that total index 6 writes to location 2.

## Guardpoint mode (2)

The guardpoint is written at the same time as location 0 is written - with the same value.

This facilitates writing to tables which are intended to be read with interpolation for producing smooth cyclic waveforms. In addition, before it is used, the total index is incremented by half the range between one location and the next, before being rounded down to the integer address of a table location.

Normally ( $igwmode = 0$  or  $1$ ) for a table of length 5 - which has locations 0 to 3 as the main table and location 4 as the guard point, a total index in the range of 0 to 0.999 will write to location 0. ("0.999" means just less than 1.0.) 1.0 to 1.999 will write to location 1 etc. A similar pattern holds for all total indexes 0 to 4.999 ( $igwmode = 0$ ) or to 3.999 ( $igwmode = 1$ ).  $igwmode = 0$  enables locations 0 to 4 to be written - with the guardpoint (4) being written with a potentially different value from location 0.

With a table of length 5 and the  $iwgmode = 2$ , then when the total index is in the range 0 to 0.499, it will write to locations 0 and 4. Range 0.5 to 1.499 will write to location 1 etc. 3.5 to 4.0 will also write to locations 0 and 4.

This way, the writing operation most closely approximates the results of interpolated reading. Guard point mode should only be used with tables that have a guardpoint.

Guardpoint mode is accomplished by adding 0.5 to the total index, rounding to the next lowest integer, wrapping it modulo the factor of two which is one less than the table length, writing the table (locations 0 to 3 in our example) and then writing to the guard point if index = 0.

## Caution with k-rate table numbers

At k-rate or a-rate, if a table number of  $< 1$  is given, or the table number points to a non-existent table, or to one which has a length of 0 (it is to be loaded from a file later) then an error will result and the instrument will be deactivated.  $kfn$  and  $afn$  must be initialized at the appropriate rate using *init*. Attempting to load an i-rate value into  $kfn$  or  $afn$  will result in an error.

# tablexkt

tablexkt — Reads function tables with linear, cubic, or sinc interpolation.

## Description

Reads function tables with linear, cubic, or sinc interpolation.

## Syntax

```
ares tablexkt xndx, kfn, kwar, iwsize [, ixmode] [, ixoff] [, iwrap]
```

## Initialization

*iwsize* -- This parameter controls the type of interpolation to be used:

- 2: Use linear interpolation. This is the lowest quality, but also the fastest mode.
- 4: Cubic interpolation. Slightly better quality than *iwsize* = 2, at the expense of being somewhat slower.
- 8 and above (up to 1024): sinc interpolation with window size set to *iwsize* (should be an integer multiply of 4). Better quality than linear or cubic interpolation, but very slow. When transposing up, a *kwar* value above 1 can be used for anti-aliasing (this is even slower).

*ixmode1* (optional) -- index data mode. The default value is 0.

- 0: raw index
- any non-zero value: normalized (0 to 1)

## Notes

if *tablexkt* is used to play back samples with looping (e.g. table index is generated by lphasor), there must be at least *iwsize* / 2 extra samples after the loop end point for interpolation, otherwise audible clicking may occur (also, at least *iwsize* / 2 samples should be before the loop start point).

*ixoff* (optional) -- amount by which index is to be offset. For a table with origin at center, use *tablesize* / 2 (raw) or 0.5 (normalized). The default value is 0.

*iwrap* (optional) -- wraparound index flag. The default value is 0.

- 0: Nowrap (index < 0 treated as index = 0; index >= *tablesize* (or 1.0 in normalized mode) sticks at the guard point).
- any non-zero value: Index is wrapped to the allowed range (not including the guard point in this case).

## Note

*iwrap* also applies to extra samples for interpolation.

## Performance

*ares* -- audio output

*xndx* -- table index

*kfn* -- function table number

*kwarp* -- if greater than 1, use  $\sin(x / \text{kwarp}) / x$  function for sinc interpolation, instead of the default  $\sin(x) / x$ . This is useful to avoid aliasing when transposing up (*kwarp* should be set to the transpose factor in this case, e.g. 2.0 for one octave), however it makes rendering up to twice as slow. Also, *iwsize* should be at least *kwarp* \* 8. This feature is experimental, and may be optimized both in terms of speed and quality in new versions.

## Note

*kwarp* has no effect if it is less than, or equal to 1, or linear or cubic interpolation is used.

## Examples

Here is an example of the *tablexkt* opcode. It uses the file *tablexkt.csd* [examples/tablexkt.csd].

# tablexseg

tablexseg — Creates a new function table by making exponential segments between values in stored function tables.

## Description

*tablexseg* is like *expseg* but interpolate between values in a stored function tables. The result is a new function table passed internally to any following *vpvoc* which occurs before a subsequent *tablexseg* (much like *lpread/lpreson* pairs work). The uses of these are described below under *vpvoc*.

## Syntax

```
tablexseg ifn1, idur1, ifn2 [, idur2] [, ifn3] [...]
```

## Initialization

*ifn1*, *ifn2*, *ifn3*, etc. -- function table numbers. *ifn1*, *ifn2*, and so on, must be the same size.

*idur1*, *idur2*, etc. -- durations during which interpolation from one table to the next will take place.

## Examples

Here is an example of the *tablexseg* opcode. It uses the file *tablexseg.csd* [examples/tablexseg.csd].

### Example 911. Example of the tablexseg opcode.

# tabmorph

*tabmorph* — Allow morphing between a set of tables.

## Description

*tabmorph* allows morphing between a set of tables of the same size, by means of a weighted average between two currently selected tables.

## Syntax

```
kout tabmorph kindex, kweightpoint, ktabnum1, ktabnum2, \
      ifn1, ifn2 [, ifn3, ifn4, ..., ifnN]
```

## Initialization

*ifn1, ifn2 [, ifn3, ifn4, ..., ifnN]* - function table numbers. This is a set of chosen tables the user want to use in the morphing. All tables must have the same length. Be aware that only two of these tables can be chosen for the morphing at one time. Since it is possible to use non-integer numbers for the *ktabnum1* and *ktabnum2* arguments, the morphing is the result from the interpolation between adjacent consecutive tables of the set.

## Performance

*kout* - The output value for index *kindex*, resulting from morphing two tables (see below).

*kindex* - main index of the morphed resultant table. The range is 0 to table\_length (not included).

*kweightpoint* - the weight of the influence of a pair of selected tables in the morphing. The range of this argument is 0 to 1. A zero makes it output the first table unaltered, a 1 makes it output the second table of the pair unaltered. All intermediate values between 0 and 1 determine the gradual morphing between the two tables of the pair.

*ktabnum1* - the first table chosen for the morphing. This number doesn't express the table number directly, but the position of the table in the set sequence (starting from 0 to N-1). If this number is an integer, the corresponding table will be chosen unaltered. If it contains fractional values, then an interpolation with the next adjacent table will result.

*ktabnum2* - the second table chosen for the morphing. This number doesn't express the table number directly, but the position of the table in the set sequence (starting from 0 to N-1). If this number is an integer, corresponding table will be chosen unaltered. If it contains fractional values, then an interpolation with the next adjacent table will result.

The *tabmorph* family of opcodes is similar to the *table* family, but allows morphing between two tables chosen into a set of tables. Firstly the user has to provide a set of tables of equal length (ifn2 [, ifn3, ifn4, ..., ifnN]). Then he can choose a pair of tables in the set in order to perform the morphing: *ktabnum1* and *ktabnum2* are filled with numbers (zero represents the first table in the set, 1 the second, 2 the third and so on). Then determine the morphing between the two chosen tables with the *kweightpoint* parameter. After that the resulting table can be indexed with the *kindex* parameter like a normal *table* opcode. If the value of this parameter surpasses the length of tables (which must be the same for all tables), then it is wrapped around.

*tabmorph* acts similarly to the *table* opcode, that is, without using interpolation. This means that it trun-

cates the fractional part of the *kindex* argument. Anyway, fractional parts of *ktabnum1* and *ktabnum2* are significant, resulting in linear interpolation between the same element of two adjacent subsequent tables.

## Examples

Here is an example of the *tabmorph* opcode. It uses the file *tabmorph.csd* [examples/tbmorph.csd].

### Example 912. Example of the *tabmorph* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# tabmorpha

`tabmorpha` — Allow morphing between a set of tables at audio rate with interpolation.

## Description

`tabmorpha` allows morphing between a set of tables of the same size, by means of a weighted average between two currently selected tables.

## Syntax

```
aout tabmorpha aindex, aweightpoint, atabnum1, atabnum2, \
      ifn1, ifn2 [, ifn3, ifn4, ... ifnN]
```

## Initialization

*ifn1, ifn2, ifn3, ifn4, ... ifnN* - function table numbers. This is a set of chosen tables the user want to use in the morphing. All tables must have the same length. Be aware that only two of these tables can be chosen for the morphing at one time. Since it is possible to use non-integer numbers for the *atabnum1* and *atabnum2* arguments, the morphing is the result from the interpolation between adjacent consecutive tables of the set.

## Performance

*aout* - The output value for index *aindex*, resulting from morphing two tables (see below).

*aindex* - main index index of the morphed resultant table. The range is 0 to *table\_length* (not included).

*aweightpoint* - the weight of the influence of a pair of selected tables in the morphing. The range of this argument is 0 to 1. A zero makes it output the first table unaltered, a 1 makes it output the second table of the pair unaltered. All intermediate values between 0 and 1 determine the gradual morphing between the two tables of the pair.

*atabnum1* - the first table chosen for the morphing. This number doesn't express the table number directly, but the position of the table in the set sequence (starting from 0 to N-1). If this number is an integer, the corresponding table will be chosen unaltered. If it contains fractional values, then an interpolation with the next adjacent table will result.

*atabnum2* - the second table chosen for the morphing. This number doesn't express the table number directly, but the position of the table in the set sequence (starting from 0 to N-1). If this number is an integer, corresponding table will be chosen unaltered. If it contains fractional values, then an interpolation with the next adjacent table will result.

The `tabmorpha` family of opcodes is similar to the `table` family, but allows morphing between two tables chosen into a set of tables. Firstly the user has to provide a set of tables of equal length (*ifn2 [, ifn3, ifn4,...ifnN]*). Then he can choose a pair of tables in the set in order to perform the morphing: *atabnum1* and *atabnum2* are filled with numbers (zero represents the first table in the set, 1 the second, 2 the third and so on). Then determine the morphing between the two chosen tables with the *aweightpoint* parameter. After that the resulting table can be indexed with the *aindex* parameter like a normal `table` opcode. If the value of this parameter surpasses the length of tables (which must be the same for all tables), then it is wrapped around.

`tabmorpha` is the audio-rate version of `tabmorphi` (it uses interpolation). All input arguments work at a-

rate.

## Examples

Here is an example of the tabmorpha opcode. It uses the file *tabmorpha.csd* [examples/tabcodex/tabcodex.csd].

# tabmorphak

`tabmorphak` — Allow morphing between a set of tables at audio rate with interpolation.

## Description

`tabmorphak` allows morphing between a set of tables of the same size, by means of a weighted average between two currently selected tables.

## Syntax

```
aout tabmorphak aindex, kweightpoint, ktabnum1, ktabnum2, \
      ifn1, ifn2 [, ifn3, ifn4, ... ifnN]
```

## Initialization

*ifn1, ifn2, ifn3, ifn4, ... ifnN* - function table numbers. This is a set of chosen tables the user want to use in the morphing. All tables must have the same length. Be aware that only two of these tables can be chosen for the morphing at one time. Since it is possible to use non-integer numbers for the *ktabnum1* and *ktabnum2* arguments, the morphing is the result from the interpolation between adjacent consecutive tables of the set.

## Performance

*aout* - The output value for index *aindex*, resulting from morphing two tables (see below).

*aindex* - main index index of the morphed resultant table. The range is 0 to *table\_length* (not included).

*kweightpoint* - the weight of the influence of a pair of selected tables in the morphing. The range of this argument is 0 to 1. A zero makes it output the first table unaltered, a 1 makes it output the second table of the pair unaltered. All intermediate values between 0 and 1 determine the gradual morphing between the two tables of the pair.

*ktabnum1* - the first table chosen for the morphing. This number doesn't express the table number directly, but the position of the table in the set sequence (starting from 0 to N-1). If this number is an integer, the corresponding table will be chosen unaltered. If it contains fractional values, then an interpolation with the next adjacent table will result.

*ktabnum2* - the second table chosen for the morphing. This number doesn't express the table number directly, but the position of the table in the set sequence (starting from 0 to N-1). If this number is an integer, corresponding table will be chosen unaltered. If it contains fractional values, then an interpolation with the next adjacent table will result.

The `tabmorphak` family of opcodes is similar to the `table` family, but allows morphing between two tables chosen into a set of tables. Firstly the user has to provide a set of tables of equal length (*ifn2* [, *ifn3*, *ifn4*, ... *ifnN*]). Then he can choose a pair of tables in the set in order to perform the morphing: *ktabnum1* and *ktabnum2* are filled with numbers (zero represents the first table in the set, 1 the second, 2 the third and so on). Then determine the morphing between the two chosen tables with the *kweightpoint* parameter. After that the resulting table can be indexed with the *aindex* parameter like a normal table opcode. If the value of this parameter surpasses the length of tables (which must be the same for all tables), then it is wrapped around.

`tabmorphak` works at a-rate, but *kweightpoint*, *ktabnum1* and *ktabnum2* are working at k-rate, making it

more efficient than *tabmorphia*, since there are less calculations. Except the rate of these three arguments, it is identical to *tabmorphia*.

## Examples

Here is an example of the tabmorphak opcode. It uses the file *tabmorphak.csd* [examples/tabcodes/tabcodes/]  
[examples/tabcodes/tabcodes/].

# tabmorphi

`tabmorphi` — Allow morphing between a set of tables with interpolation.

## Description

*tabmorphi* allows morphing between a set of tables of the same size, by means of a weighted average between two currently selected tables.

## Syntax

```
kout tabmorphi kindex, kweightpoint, ktabnum1, ktabnum2, \
      ifn1, ifn2 [, ifn3, ifn4, ..., ifnN]
```

## Initialization

*ifn1, ifn2 [, ifn3, ifn4, ..., ifnN]* - function table numbers. This is a set of chosen tables the user want to use in the morphing. All tables must have the same length. Be aware that only two of these tables can be chosen for the morphing at one time. Since it is possible to use non-integer numbers for the *ktabnum1* and *ktabnum2* arguments, the morphing is the result from the interpolation between adjacent consecutive tables of the set.

## Performance

*kout* - The output value for index *kindex*, resulting from morphing two tables (see below).

*kindex* - main index index of the morphed resultant table. The range is 0 to *table\_length* (not included).

*kweightpoint* - the weight of the influence of a pair of selected tables in the morphing. The range of this argument is 0 to 1. A zero makes it output the first table unaltered, a 1 makes it output the second table of the pair unaltered. All intermediate values between 0 and 1 determine the gradual morphing between the two tables of the pair.

*ktabnum1* - the first table chosen for the morphing. This number doesn't express the table number directly, but the position of the table in the set sequence (starting from 0 to N-1). If this number is an integer, the corresponding table will be chosen unaltered. If it contains fractional values, then an interpolation with the next adjacent table will result.

*ktabnum2* - the second table chosen for the morphing. This number doesn't express the table number directly, but the position of the table in the set sequence (starting from 0 to N-1). If this number is an integer, corresponding table will be chosen unaltered. If it contains fractional values, then an interpolation with the next adjacent table will result.

The *tabmorphi* family of opcodes is similar to the *table* family, but allows morphing between two tables chosen into a set of tables. Firstly the user has to provide a set of tables of equal length (ifn2 [, ifn3, ifn4, ..., ifnN]). Then he can choose a pair of tables in the set in order to perform the morphing: *ktabnum1* and *ktabnum2* are filled with numbers (zero represents the first table in the set, 1 the second, 2 the third and so on). Then determine the morphing between the two chosen tables with the *kweightpoint* parameter. After that the resulting table can be indexed with the *kindex* parameter like a normal *table* opcode. If the value of this parameter surpasses the length of tables (which must be the same for all tables), then it is wrapped around.

*tabmorphi* is identical to *tabmorph*, but it performs linear interpolation for non-integer values of *kindex*.

much like *tablei*.

## Examples

Here is an example of the tabmorphi opcode. It uses the file *tabmorphi.csd* [examples/tabmorphi.csd].

# tabplay

`tabplay` — Playing-back control signals.

## Description

Plays-back control-rate signals on trigger-temporization basis.

## Syntax

```
tabplay ktrig, knumtics, kfn, kout1 [,kout2,..., koutN]
```

## Performance

*ktrig* -- starts playing when non-zero.

*knumtics* -- stop recording or reset playing pointer to zero when the number of tics defined by this argument is reached.

*kfn* -- table where k-rate signals are recorded.

*kout1,...,koutN* -- playback output signals.

The *tabplay* and *tabrec* opcodes allow to record/playback control signals on trigger-temporization basis.

*tabplay* plays back a group of k-rate signals, previously recorded by *tabrec* into a table. Each time *ktrig* argument is triggered, an internal counter is increased of one unit. After *knumtics* trigger impulses are received by *ktrig* argument, the internal counter is zeroed and playback is restarted from the beginning, in looping style.

These opcodes can be used like a sort of ``middle-term'' memory that ``remembers'' generated signals. Such memory can be used to supply generative music with a coherent iterative compositional structure.

## See Also

*tabrec*

# tabrec

tabrec — Recording of control signals.

## Description

Records control-rate signals on trigger-temporization basis.

## Syntax

```
tabrec  ktrig_start, ktrig_stop, knumtics, kfn, kin1 [,kin2,...,kinN]
```

## Performance

*ktrig\_start* -- start recording when non-zero.

*ktrig\_stop* -- stop recording when *knumtics* trigger impulses are received by this input argument.

*knumtics* -- stop recording or reset playing pointer to zero when the number of tics defined by this argument is reached.

*kfn* -- table where k-rate signals are recorded.

*kin1,...,kinN* -- input signals to record.

The *tabrec* and *tabplay* opcodes allow to record/playback control signals on trigger-temporization basis.

*tabrec* opcode records a group of k-rate signals by storing them into *kfn* table. Each time *ktrig\_start* is triggered, *tabrec* resets the table pointer to zero and begins to record. Recording phase stops after *knumtics* trigger impulses have been received by *ktrig\_stop* argument.

These opcodes can be used like a sort of ``middle-term'' memory that ``remembers'' generated signals. Such memory can be used to supply generative music with a coherent iterative compositional structure.

# tabsum

tabsum — Adding values in a range of a table.

## Description

Sums the values in an f-table in a consecutive range.

## Syntax

```
kr tabsum ifn[, kmin] [, kmax]
```

## Initialization

*ifn* -- table number

## Performance

*kr* -- input signal to write.

*kmin*, *kmax* -- range of the table to sum. If omitted or zero they default to 0 to length of the table.

## Examples

Here is an example of the tabsum opcode. It uses the file *tabsum.csd* [examples/tabsum.csd].

### Example 916. Example of the tabsum opcode.

# tab2pvs

tab2pvs — Copies spectral data from k-rate arrays (or t-variables.). Also known as pvsfromarray.

## Description

Copies a pvs frame from a t-variable or k-rate array. Currently only AMP+FREQ is produced. This opcode requires the t-type to be defined, which means it only works in the new bison/flex-based parser.

## Syntax

```
fsig tab2pvs tvar|karr[],ihopsize, iwinsize, iwinstype]
```

## Performance

*tvar* -- k-rate array (or t-variable) containing the input. It is produced at every k-period, but may not contain a new frame, pvs frames are produced at their own frame rate that is independent of kr. The size of this vector will determine the fftsize, N = size - 2.

*fsig* -- output fsig to be copied.

*iolap* -- size of the analysis overlap, defaults to  *isize/4*.

*iwinsize* -- size of the analysis window, defaults to  *isize*.

*iwinstype* -- type of analysis window, defaults to 1, Hanning.

## Examples

### Example 917. Example

```
karr[] init 1026

# tambourine

tambourine — Semi-physical model of a tambourine sound.

## Description

*tambourine* is a semi-physical model of a tambourine sound. It is one of the PhISEM percussion opcodes. PhISEM (Physically Informed Stochastic Event Modeling) is an algorithmic approach for simulating collisions of multiple independent sound producing objects.

## Syntax

```
ares tambourine kamp, idettack [, inum] [, idamp] [, imaxshake] [, ifreq] \
[, ifreq1] [, ifreq2]
```

## Initialization

*idettack* -- period of time over which all sound is stopped

*inum* (optional) -- The number of beads, teeth, bells, timbrels, etc. If zero, the default value is 32.

*idamp* (optional) -- the damping factor, as part of this equation:

$$\text{damping\_amount} = 0.9985 + (\text{idamp} * 0.002)$$

The default *damping\_amount* is 0.9985 which means that the default value of *idamp* is 0. The maximum *damping\_amount* is 1.0 (no damping). This means the maximum value for *idamp* is 0.75.

The recommended range for *idamp* is usually below 75% of the maximum value.

*imaxshake* (optional, default=0) -- amount of energy to add back into the system. The value should be in range 0 to 1.

*ifreq* (optional) -- the main resonant frequency. The default value is 2300.

*ifreq1* (optional) -- the first resonant frequency. The default value is 5600.

*ifreq2* (optional) -- the second resonant frequency. The default value is 8100.

## Performance

*kamp* -- Amplitude of output. Note: As these instruments are stochastic, this is only an approximation.

## Examples

Here is an example of the tambourine opcode. It uses the file *tambourine.csd* [examples/tambourine.csd].

### Example 918. Example of the tambourine opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# taninv2

`taninv2` — Returns an arctangent.

## Description

Returns the arctangent of  $iy/ix$ ,  $ky/kx$ , or  $ay/ax$ .

## Syntax

```
ares taninv2 ay, ax  
  
ires taninv2 iy, ix  
  
kres taninv2 ky, kx  
  
. . . taninv2(ky, kx) . . . (no rate restriction)
```

Returns the arctangent of  $iy/ix$ ,  $ky/kx$ , or  $ay/ax$ . If  $y$  is zero, `taninv2` returns zero regardless of the value of  $x$ . If  $x$  is zero, the return value is:

- $\#2$ , if  $y$  is positive.
- $-\#2$ , if  $y$  is negative.
- $0$ , if  $y$  is 0.

## Initialization

$iy, ix$  -- values to be converted

## Performance

$ky, kx$  -- control rate signals to be converted

$ay, ax$  -- audio rate signals to be converted

## Examples

Here is an example of the `taninv2` opcode. It uses the file `taninv2.csd` [examples/taninv2.csd].

### Example 922. Example of the taninv2 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# tbvcf

**tbvcf** — Models some of the filter characteristics of a Roland TB303 voltage-controlled filter.

## Description

This opcode attempts to model some of the filter characteristics of a Roland TB303 voltage-controlled filter. Euler's method is used to approximate the system, rather than traditional filter methods. Cutoff frequency, Q, and distortion are all coupled. Empirical methods were used to try to unentwine, but frequency is only approximate as a result. Future fixes for some problems with this opcode may break existing orchestras relying on this version of *tbvcf*.

## Syntax

```
ares tbvcf asig, xfco, xres, kdist, kasym [, iskip]
```

## Initialization

*iskip* (optional, default=0) -- if non zero skip the initialisation of the filter. (New in Csound version 4.23f13 and 5.0)

## Performance

*asig* -- input signal. Should be normalized to  $\pm 1$ .

*xfco* -- filter cutoff frequency. Optimum range is 10,000 to 1500. Values below 1000 may cause problems.

*xres* -- resonance or Q. Typically in the range 0 to 2.

*kdist* -- amount of distortion. Typical value is 2. Changing *kdist* significantly from 2 may cause odd interaction with *xfco* and *xres*.

*kasym* -- asymmetry of resonance. Typically in the range 0 to 1.

## Examples

Here is an example of the tbvcf opcode. It uses the file *tbvcf.csd* [examples/tbvcf.csd].

### Example 923. Example of the tbvcf opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# tempest

tempest — Estimate the tempo of beat patterns in a control signal.

## Description

Estimate the tempo of beat patterns in a control signal.

## Syntax

```
ktemp tempest kin, iprd, imindur, imemdur, ihp, ithresh, ihtim, ixfdbak, \
istarttempo, ifn [, idisprd] [, itweek]
```

## Initialization

*iprd* -- period between analyses (in seconds). Typically about .02 seconds.

*imindur* -- minimum duration (in seconds) to serve as a unit of tempo. Typically about .2 seconds.

*imemdur* -- duration (in seconds) of the *kin* short-term memory buffer which will be scanned for periodic patterns. Typically about 3 seconds.

*ihp* -- half-power point (in Hz) of a low-pass filter used to smooth input *kin* prior to other processing. This will tend to suppress activity that moves much faster. Typically 2 Hz.

*ithresh* -- loudness threshold by which the low-passed *kin* is center-clipped before being placed in the short-term buffer as tempo-relevant data. Typically at the noise floor of the incoming data.

*ihtim* -- half-time (in seconds) of an internal forward-masking filter that masks new *kin* data in the presence of recent, louder data. Typically about .005 seconds.

*ixfdbak* -- proportion of this unit's *anticipated value* to be mixed with the incoming *kin* prior to all processing. Typically about .3.

*istarttempo* -- initial tempo (in beats per minute). Typically 60.

*ifn* -- table number of a stored function (drawn left-to-right) by which the short-term memory data is attenuated over time.

*idisprd* (optional) -- if non-zero, display the short-term past and future buffers every *idisprd* seconds (normally a multiple of *iprd*). The default value is 0 (no display).

*itweek* (optional) -- fine-tune adjust this unit so that it is stable when analyzing events controlled by its own output. The default value is 1 (no change).

## Performance

*tempest* examines *kin* for amplitude periodicity, and estimates a current tempo. The input is first low-pass filtered, then center-clipped, and the residue placed in a short-term memory buffer (attenuated over time) where it is analyzed for periodicity using a form of autocorrelation. The period, expressed as a *tempo* in beats per minute, is output as *ktemp*. The period is also used internally to make predictions about future amplitude patterns, and these are placed in a buffer adjacent to that of the input. The two adjacent buffers can be periodically displayed, and the predicted values optionally mixed with the in-

coming signal to simulate expectation.

This unit is useful for sensing the metric implications of any k-signal (e.g.- the RMS of an audio signal, or the second derivative of a conducting gesture), before sending to a *tempo* statement.

## Examples

Here is an example of the tempest opcode. It uses the file *tempest.csd* [examples/tempest.csd], and *beats.wav* [examples/beats.wav].

### Example 924. Example of the tempest opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

e

</CsScore>
</CsoundSynthesizer>
```

The tempo of the audio file “beats.wav” is 120 beats per minute. In this examples, tempest will print out its best guess as the audio file plays. Its output should include lines like this:

```
. i1    118.24654  
. i1    121.72949
```

# tempo

`tempo` — Apply tempo control to an uninterpreted score.

## Description

Apply tempo control to an uninterpreted score.

## Syntax

```
tempo ktempo, istarttempo
```

## Initialization

*istarttempo* -- initial tempo (in beats per minute). Typically 60.

## Performance

*ktempo* -- The tempo to which the score will be adjusted.

*tempo* allows the performance speed of Csound scored events to be controlled from within an orchestra. It operates only in the presence of the Csound *-t* flag. When that flag is set, scored events will be performed from their uninterpreted p2 and p3 (beat) parameters, initially at the given command-line tempo. When a *tempo* statement is activated in any instrument (*ktempo* 0.), the operating tempo will be adjusted to *ktempo* beats per minute. There may be any number of *tempo* statements in an orchestra, but coincident activation is best avoided.

## Examples

Here is an example of the *tempo* opcode. Remember, it only works if you use the *-t* flag with Csound. The example uses the file *tempo.csd* [examples/tempo.csd].

### Example 925. Example of the *tempo* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# tempascal

*tempascal* — Phase-locked vocoder processing with onset detection/processing, 'tempo-scaling'.

## Description

*tempascal* implements phase-locked vocoder processing using function tables containing sampled-sound sources, with *GEN01*, and *tempascal* will accept deferred allocation tables.

This opcode allows for time and frequency-independent scaling. Time is advanced internally, but controlled by a tempo scaling parameter; when an onset is detected, timescaling is momentarily stopped to avoid smearing of attacks. The quality of the effect is generally improved with phase locking switched on.

*tempascal* will also scale pitch, independently of frequency, using a transposition factor (k-rate).

## Syntax

```
asig tempascal ktimescal, kamp, kpitch, ktab, klock [,ifftsize, idecim, ithresh]
```

## Initialization

*ifftsize* -- FFT size (power-of-two), defaults to 2048.

*idecim* -- decimation, defaults to 4 (meaning hopsize = ifftsize/4)

*idbthresh* -- threshold based on dB power spectrum ratio between two successive windows. A detected ratio above it will cancel timescaling momentarily, to avoid smearing (defaults to 1)

## Performance

*ktimescal* -- timescaling ratio, < 1 stretch, > 1 contract.

*kamp* -- amplitude scaling

*kpitch* -- grain pitch scaling (1=normal pitch, < 1 lower, > 1 higher; negative, backwards)

*klock* -- 0 or 1, to switch phase-locking on/off

*ktab* -- source signal function table. Deferred-allocation tables (see *GEN01*) are accepted, but the opcode expects a mono source. Tables can be switched at k-rate.

## Examples

Here is an example of the tempascal opcode. It uses the file *tempascal.csd* [examples/tempascal.csd].

### Example 926. Example of the tempascal opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# tempoval

tempoval — Reads the current value of the tempo.

## Description

Reads the current value of the tempo.

## Syntax

```
kres tempoval
```

## Performance

*kres* -- the value of the tempo. If you use a positive value with the *-t command-line flag*, *tempoval* returns the percentage increase/decrease from the original tempo of 60 beats per minute. If you don't, its value will be 60 (for 60 beats per minute).

## Examples

Here is an example of the *tempoval* opcode. Remember, it only works if you use the *-t* flag with Csound. It uses the file *tempoval.csd* [examples/tempoval.csd].

### Example 927. Example of the tempoval opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
; Audio out    Audio in
-odac          -iadc    -t60 ;;;RT audio I/O
; For Non-realtime output leave only the line below:
; -o tempoval.wav -W -t60 ;;; for file output any platform
</CsOptions>
<CsInstruments>

; Initialize the global variables.
sr = 44100
kr = 4410
ksmps = 10
nchnls = 1

; Instrument #1.
instr 1
; Adjust the tempo to 120 beats per minute.
tempo 120, 60

; Get the tempo value.
kval tempoval

printks "kval = %f\n", 0.1, kval
endin

</CsInstruments>
<CsScore>
```

```
; Play Instrument #1 for one second.  
i 1 0 1  
e  
  
</CsScore>  
</CsoundSynthesizer>
```

Since 120 beats per minute is a 50% increase over the original 60 beats per minute, its output should include lines like:

```
kval = 0.500000
```

# tigoto

tigoto — Transfer control at i-time when a new note is being tied onto a previously held note

## Description

Similar to *igoto* but effective only during an i-time pass at which a new note is being “tied” onto a previously held note. (See *i Statement*) It does not work when a tie has not taken place. Allows an instrument to skip initialization of units according to whether a proposed tie was in fact successful. (See also *tival*).

## Syntax

```
tigoto label
```

where *label* is in the same instrument block and is not an expression.

## Examples

Here is an example of the tigoto opcode. It uses the file *tigoto.csd* [examples/tigoto.csd].

### Example 928. Example of the tigoto opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# timedseq

timedseq — Time Variant Sequencer

## Description

An event-sequencer in which time can be controlled by a time-pointer. Sequence data are stored into a table.

## Syntax

```
ktrig  timedseq  ktmpnt, ifn, kp1 [,kp2, kp3, ...,kpN]
```

## Initialization

*ifn* -- number of table containing sequence data.

## Performance

*ktrig* -- output trigger signal

*ktmpnt* -- time pointer into sequence file, in seconds.

*kp1,...,kpN* -- output p-fields of notes. *kp2* meaning is relative action time and *kp3* is the duration of notes in seconds.

*timedseq* is a sequencer that allows to schedule notes starting from a user sequence, and depending from an external timing given by a time-pointer value (*ktmpnt* argument). User should fill table *ifn* with a list of notes, that can be provided in an external text file by using GEN23, or by typing it directly in the orchestra (or score) file with GEN02. The format of the text file containing the sequence is made up simply by rows containing several numbers separated by space (similarly to normal Csound score). The first value of each row must be a positive or null value, except for a special case that will be explained below. This first value is normally used to define the instrument number corresponding to that particular note (like normal score). The second value of each row must contain the action time of corresponding note and the third value its duration. This is an example:

```
0 0    0.25 1  93
0 0.25 0.25 2  63
0 0.5   0.25 3  91
0 0.75  0.25 4  70
0 1     0.25 5  83
0 1.25  0.25 6  75
0 1.5   0.25 7  78
0 1.75  0.25 8  78
0 2     0.25 9  83
0 2.25  0.25 10 70
0 2.5   0.25 11 54
0 2.75  0.25 12 80
-1 3    -1   -1 -1  ;; last row of the sequence
```

In this example, the first value of each row is always zero (it is a dummy value, but this p-field can be used, for example, to express a MIDI channel or an instrument number), except the last row, that begins with -1. This value (-1) is a special value, that indicates the end of sequence. It has itself an action time, because sequences can be looped. So the previous sequence has a default duration of 3 seconds, being value 3 the last action time of the sequence.

It is important that ALL lines contains the same number of values (in the example all rows contains exactly 5 values). The number of values contained by each row, MUST be the number of kpXX output arguments (notice that, even if kp1, kp2 etc. are placed at the right of the opcode, they are output arguments, not input arguments).

ktimpnt argument provide the real temporization of the sequence. Actually the passage of time through sequence is specified by ktmpnt itself, which represents the time in seconds. ktmpnt must always be positive, but can move forwards or backwards in time, be stationary or discontinuous, as a pointer into the sequence file, in the same way of pvoc or lpread. When ktmpnt crosses the action time of a note, a trigger signal is sent to ktrig output argument, and kp1, kp2,...kpN arguments are updated with the values of that note. This information can then be used with schedkwhen to actually activate note events. Notice that kp1,...kpn data can be further processed (for example delayed with delayk, transposed, etc.) before feeding schedkwhen.

*ktimpnt* can be controlled by a linear signal, for example:

```
ktmpnt line 0, p3, 3 ; original sequence duration was 3 secs
ktrig timedseq ktmpnt, 1, kp1, kp2, kp3, kp4, kp5
        schedkwhen ktrig, 105, 2, 0, kp3, kp4, kp5
```

in this case the complete sequence (with original duration of 3 seconds) will be played in *p3* seconds.

You can loop a sequence by controlling it with a phasor:

```
kphs phasor 1/3
ktmpnt = kphs * 3
ktrig timedseq ktmpnt, 1, kp1, kp2, kp3, kp4, kp5
        schedkwhen ktrig, 105, 2, 0, kp3, kp4, kp5
```

Obviously you can play only a fragment of the sequence, read it backward, and non-linearly access sequence data in the same way of pvoc and lpread opcodes.

With timedseq opcode you can do almost all things of a normal score, except you have the following limitations:

1. You can't have two notes exactly starting with the same action time; actually at least a k-cycle should separate timing of two notes (otherwise the schedkwhen mechanism eats one of them).
2. All notes of the sequence must have the same number of p-fields (even if they activate different instruments).

You can remedy this limitation by filling with dummy values notes that belongs to instruments with less p-fields than other ones.

## Examples

Here is a complete example of the timedseq opcode. It uses the file *timedseq.csd* [examples/timedseq.csd].

### Example 929. Example of the timedseq opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# timeinstk

timeinstk — Read absolute time in k-rate cycles.

## Description

Read absolute time, in k-rate cycles, since the start of an instance of an instrument. Called at both i-time as well as k-time.

## Syntax

```
kres timeinstk
```

## Performance

*timeinstk* is for time in k-rate cycles. So with:

```
sr      = 44100
kr      = 6300
ksmps  = 7
```

then after half a second, the *timeinstk* opcode would report 3150. It will always report an integer.

*timeinstk* produces a k-rate variable for output. There are no input parameters.

*timeinstk* is similar to *timek* except it returns the time since the start of this instance of the instrument.

## Examples

Here is an example of the *timeinstk* opcode. It uses the file *timeinstk.csd* [examples/timeinstk.csd].

### Example 930. Example of the *timeinstk* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>

# timeinsts

timeinsts — Read absolute time in seconds.

## Description

Read absolute time, in seconds, since the start of an instance of an instrument.

## Syntax

```
kres timeinsts
```

## Performance

Time in seconds is available with *timeinsts*. This would return 0.5 after half a second.

*timeinsts* produces a k-rate variable for output. There are no input parameters.

*timeinsts* is similar to *times* except it returns the time since the start of this instance of the instrument.

## Examples

Here is an example of the *timeinsts* opcode. It uses the file *timeinsts.csd* [examples/timeinsts.csd].

### Example 931. Example of the timeinsts opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# timek

timek — Read absolute time in k-rate cycles.

## Description

Read absolute time, in k-rate cycles, since the start of the performance.

## Syntax

```
iros timek  
  
kres timek
```

## Performance

*timek* is for time in k-rate cycles. So with:

```
sr      = 44100  
kr      = 6300  
ksmps  = 7
```

then after half a second, the *timek* opcode would report 3150. It will always report an integer.

*timek* can produce a k-rate variable for output. There are no input parameters.

*timek* can also operate only at the start of the instance of the instrument. It produces an i-rate variable (starting with *i* or *gi*) as its output.

## Examples

Here is an example of the timek opcode. It uses the file *timek.csd* [examples/timek.csd].

### Example 932. Example of the timek opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# timout

timout — Conditional branch during p-time depending on elapsed note time.

## Description

Conditional branch during p-time depending on elapsed note time. *istrt* and *idur* specify time in seconds. The branch to *label* will become effective at time *istrt*, and will remain so for just *idur* seconds. Note that *timeout* can be reinitialized for multiple activation within a single note (see example under *reinit*).

## Syntax

```
timout istrt, idur, label
```

where *label* is in the same instrument block and is not an expression.

## Examples

Here is an example of the timout opcode. It uses the file *timout.csd* [examples/timout.csd].

### Example 934. Example of the timout opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# tival

tival — Puts the value of the instrument's internal “tie-in” flag into the named i-rate variable.

## Syntax

```
ir tival
```

## Description

Puts the value of the instrument's internal “tie-in” flag into the named i-rate variable.

## Initialization

Puts the value of the instrument's internal “tie-in” flag into the named i-rate variable. Assigns 1 if this note has been “tied” onto a previously held note (see *i statement*); assigns 0 if no tie actually took place. (See also *tigoto*.)

## Examples

Here is an example of the tival opcode. It uses the file *tival.csd* [examples/tival.csd].

### Example 935. Example of the tival opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# tlineto

`tlineto` — Generate glissandos starting from a control signal.

## Description

Generate glissandos starting from a control signal with a trigger.

## Syntax

```
kres tlineto ksig, ktime, ktrig
```

## Performance

*kres* -- Output signal.

*ksig* -- Input signal.

*ktime* -- Time length of glissando in seconds.

*ktrig* -- Trigger signal.

*tlineto* is similar to *lineto* but can be applied to any kind of signal (not only stepped signals) without producing discontinuities. Last value of each segment is sampled and held from input signal each time *ktrig* value is set to a nonzero value. Normally *ktrig* signal consists of a sequence of zeroes (see *trigger opcode*).

The effect of glissando is quite different from *port*. Since in these cases, the lines are straight. Also the context of usage is different.

## Examples

Here is an example of the *tlineto* opcode. It uses the file *tlineto.csd* [examples/tlineto.csd].

### Example 936. Example of the tlineto opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## tone

*tone* — A first-order recursive low-pass filter with variable frequency response.

## Description

A first-order recursive low-pass filter with variable frequency response.

*tone* is a 1 term IIR filter. Its formula is:

$$y_n = c1 * x_n + c2 * y_{n-1}$$

where

- $b = 2 - \cos(2 \# hp/sr)$ ;
- $c2 = b - \sqrt{b^2 - 1.0}$
- $c1 = 1 - c2$

## Syntax

```
ares tone asig, khp [, iskip]
```

## Initialization

*iskip* (optional, default=0) -- initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*ares* -- the output audio signal.

*asig* -- the input audio signal.

*khp* -- the response curve's half-power point, in Hertz. Half power is defined as peak power / root 2.

*tone* implements a first-order recursive low-pass filter in which the variable *khp* (in Hz) determines the response curve's half-power point. Half power is defined as peak power / root 2.

## Examples

Here is an example of the tone opcode. It uses the file *tone.csd* [examples/tone.csd].

### Example 937. Example of the tone opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# tonek

`tonek` — A first-order recursive low-pass filter with variable frequency response.

## Description

A first-order recursive low-pass filter with variable frequency response.

## Syntax

```
kres tonek ksig, khp [, iskip]
```

## Initialization

*iskip* (optional, default=0) -- initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*kres* -- the output signal at control-rate.

*ksig* -- the input signal at control-rate.

*khp* -- the response curve's half-power point, in Hertz. Half power is defined as peak power / root 2.

*tonek* is like *tone* except its output is at control-rate rather than audio rate.

## Examples

Here is an example of the *tonek* opcode. It uses the file *tonek.csd* [examples/tonek.csd].

### Example 938. Example of the tonek opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# tonex

tonex — Emulates a stack of filters using the tone opcode.

## Description

*tonex* is equivalent to a filter consisting of more layers of *tone* with the same arguments, serially connected. Using a stack of a larger number of filters allows a sharper cutoff. They are faster than using a larger number instances in a Csound orchestra of the old opcodes, because only one initialization and k- cycle are needed at time and the audio loop falls entirely inside the cache memory of processor.

## Syntax

```
ares tonex asig, khp [, inumlayer] [, iskip]  
  
ares tonex asig, ahp [, inumlayer] [, iskip]
```

## Initialization

*inumlayer* (optional) -- number of elements in the filter stack. Default value is 4.

*iskip* (optional, default=0) -- initial disposition of internal data space. Since filtering incorporates a feedback loop of previous output, the initial status of the storage space used is significant. A zero value will clear the space; a non-zero value will allow previous information to remain. The default value is 0.

## Performance

*asig* -- input signal

*khp/ahp* -- the response curve's half-power point. Half power is defined as peak power / root 2.

## Examples

Here is an example of the tonex opcode. It uses the file *tonex.csd* [examples/tonex.csd].

### Example 939. Example of the tonex opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# trandom

trandom — Generates a controlled pseudo-random number series between min and max values according to a trigger.

## Description

Generates a controlled pseudo-random number series between min and max values at k-rate whenever the trigger parameter is different to 0.

## Syntax

```
kout trandom ktrig, kmin, kmax
```

## Performance

*ktrig* -- trigger (opcode produces a new random number whenever this value is not 0.)

*kmin* -- minimum range limit

*kmax* -- maximum range limit

*trandom* is almost identical to *random* opcode, except *trandom* updates its output with a new random value only when the *ktrig* argument is triggered (i.e. whenever it is not zero).

## Examples

Here is an example of the trandom opcode. It uses the file *trandom.csd* [examples/trandom.csd].

### Example 940. Example of the trandom opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# tradsyn

tradsyn — Streaming partial track additive synthesis

## Description

The *tradsyn* opcode takes an input containing a TRACKS pv streaming signal (as generated, for instance by *partials*), as described in Lazzarini et al, "Time-stretching using the Instantaneous Frequency Distribution and Partial Tracking", Proc.of ICMC05, Barcelona. It resynthesises the signal using linear amplitude and frequency interpolation to drive a bank of interpolating oscillators with amplitude and pitch scaling controls.

## Syntax

```
asig tradsyn fin, kscal, kpitch, kmaxtracks, ifn
```

## Performance

*asig* -- output audio rate signal

*fin* -- input pv stream in TRACKS format

*kscal* -- amplitude scaling

*kpitch* -- pitch scaling

*kmaxtracks* -- max number of tracks in resynthesis. Limiting this will cause a non-linear filtering effect, by discarding newer and higher-frequency tracks (tracks are ordered by start time and ascending frequency, respectively)

*ifn* -- function table containing one cycle of a sinusoid (sine or cosine).

## Examples

Here is an example of the tradsyn opcode. It uses the file *tradsyn.csd* [examples/tradsyn.csd].

### Example 941. Example of the tradsyn opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# transeg

transeg — Constructs a user-definable envelope.

## Description

Constructs a user-definable envelope.

## Syntax

```
ares transeg ia, idur, itype, ib [, idur2] [, itype] [, ic] ...
```

```
kres transeg ia, idur, itype, ib [, idur2] [, itype] [, ic] ...
```

## Initialization

*ia* -- starting value.

*ib, ic, etc.* -- value after *idur* seconds.

*idur* -- duration in seconds of first segment. A zero or negative value will cause all initialization to be skipped.

*idur2,... idurx etc.* -- duration in seconds of segment

*itype, itype2, etc.* -- if 0, a straight line is produced. If non-zero, then *transeg* creates the following curve, for *n* steps:

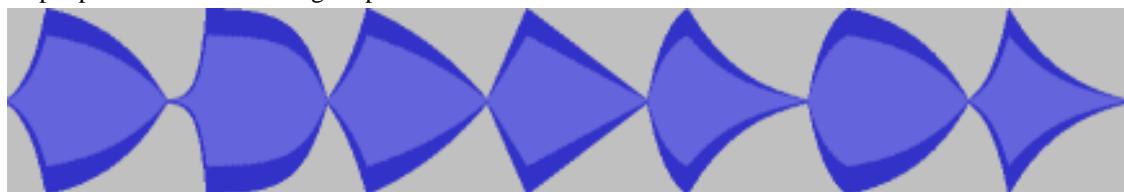

$$\text{ibeg} + (\text{ivalue} - \text{ibeg}) * (1 - \exp(-\text{i} * \text{itype}/(\text{n}-1))) / (1 - \exp(-\text{itype}))$$

## Performance

If *itype* > 0, there is a slowly rising (concave) or slowly decaying (convex) curve, while if *itype* < 0, the curve is fast rising (convex) or fast decaying (concave). See also *GEN16*.

## Examples

Here is an example of the *transeg* opcode. It uses the file *transeg.csd* [examples/transeg.csd]. The example produces the following output:

Output of the *transeg* example.

### Example 942. Example of the transeg opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# transegb

transegb — Constructs a user-definable envelope in absolute time.

## Description

Constructs a user-definable envelope in absolute time.

## Syntax

```
ares transegb ia, itim, itype, ib [, itim2] [, itype] [, ic] ...
```

```
kres transegb ia, itim, itype, ib [, itim2] [, itype] [, ic] ...
```

## Initialization

*ia* -- starting value.

*ib*, *ic*, etc. -- value after *itim* seconds.

*itim* -- time in seconds of end of first segment.

*itim2*...*itimx* etc. -- time in seconds at the end of the segment.

*itype*, *itype2*, etc. -- if 0, a straight line is produced. If non-zero, then *transegb* creates the following curve, for *n* steps:

$$\text{ibeg} + (\text{ivalue} - \text{ibeg}) * (1 - \exp(-\text{i} * \text{itype}/(\text{n}-1))) / (1 - \exp(-\text{itype}))$$

## Performance

If *itype* > 0, there is a slowly rising (concave) or slowly decaying (convex) curve, while if *itype* < 0, the curve is fast rising (convex) or fast decaying (concave). See also *GEN16*.

## Examples

Here is an example of the transegb opcode. It uses the file *transegb.csd* [examples/transegb.csd]. The example produces the following output:

Output of the transegb example.

### Example 943. Example of the transegb opcode.

# transegr

**transegr** — Constructs a user-definable envelope with extended release segment.

## Description

Constructs a user-definable envelope. It is the same as *transeg*, with an extended release segment.

## Syntax

```
ares transegr ia, idur, itype, ib [, idur2] [, itype] [, ic] ...
```

```
kres transegr ia, idur, itype, ib [, idur2] [, itype] [, ic] ...
```

## Initialization

*ia* -- starting value.

*ib, ic*, etc. -- value after *idur* seconds.

*idur* -- duration in seconds of first segment. A zero or negative value will cause all initialization to be skipped.

*idur2,... idurx* etc. -- duration in seconds of segment

*itype, itype2, etc.* -- if 0, a straight line is produced. If non-zero, then *transegr* creates the following curve, for *n* steps:

$$\text{ibeg} + (\text{ivalue} - \text{ibeg}) * (1 - \exp(-\text{i} * \text{itype}/(\text{n}-1))) / (1 - \exp(-\text{itype}))$$

## Performance

If *itype* > 0, there is a slowly rising (concave) or slowly decaying (convex) curve, while if *itype* < 0, the curve is fast rising (convex) or fast decaying (concave). See also *GEN16*.

This opcode is the same as of *transeg* with an additional release segment triggered by a MIDI noteoff event, a negative p1 *note event* in the score or a *turnoff2* opcode.

## Examples

Here is an example of the *transegr* opcode. It uses the file *transegr.csd* [examples/transegr.csd].

### Example 944. Example of the *transegr* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# trcross

trcross — Streaming partial track cross-synthesis.

## Description

The *trcross* opcode takes two inputs containing TRACKS pv streaming signals (as generated, for instance by *partials*) and cross-synthesises them into a single TRACKS stream. Two different modes of operation are used: mode 0, cross-synthesis by multiplication of the amplitudes of the two inputs and mode 1, cross-synthesis by the substitution of the amplitudes of input 1 by the input 2. Frequencies and phases of input 1 are preserved in the output. The cross-synthesis is done by matching tracks between the two inputs using a 'search interval'. The matching algorithm will look for tracks in the second input that are within the search interval around each track in the first input. This interval can be changed at the control rate. Wider search intervals will find more matches.

## Syntax

```
fsig trcross fin1, fin2, ksearch, kdepth [, kmode]
```

## Performance

*fsig* -- output pv stream in TRACKS format

*fin1* -- first input pv stream in TRACKS format.

*fin2* -- second input pv stream in TRACKS format

*ksearch* -- search interval ratio, defining a 'search area' around each track of 1st input for matching purposes.

*kdepth* -- depth of effect (0-1).

*kmode* -- mode of cross-synthesis. 0, multiplication of amplitudes (filtering), 1, substitution of amplitudes of input 1 by input 2 (akin to vocoding). Defaults to 0.

## Examples

Here is an example of the trcross opcode. It uses the file *trcross.csd* [examples/trcross.csd].

### Example 945. Example of the trcross opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# trfilter

trfilter — Streaming partial track filtering.

## Description

The *trfilter* opcode takes an input containing a TRACKS pv streaming signal (as generated, for instance by *partials*) and filters it using an amplitude response curve stored in a function table. The function table can have any size (no restriction to powers-of-two). The table lookup is done by linear-interpolation. It is possible to create time-varying filter curves by updating the amplitude response table with a table-writing opcode.

## Syntax

```
fsig trfilter fin, kamnt, ifn
```

## Performance

*fsig* -- output pv stream in TRACKS format

*fin* -- input pv stream in TRACKS format

*kamnt* -- amount of filtering (0-1)

*ifn* -- function table number. This will contain an amplitude response curve, from 0 Hz to the Nyquist (table indexes 0 to N). Any size is allowed. Larger tables will provide a smoother amplitude response curve. Table reading uses linear interpolation.

## Examples

Here is an example of the trfilter opcode. It uses the file *trfilter.csd* [examples/trfilter.csd].

### Example 946. Example of the trfilter opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# trhighest

`trhighest` — Extracts the highest-frequency track from a streaming track input signal.

## Description

The `trhighest` opcode takes an input containing TRACKS pv streaming signals (as generated, for instance by `partials`) and outputs only the highest track. In addition it outputs two k-rate signals, corresponding to the frequency and amplitude of the highest track signal.

## Syntax

```
fsig, kfr, kamp trhighest fin1, kscal
```

## Performance

*fsig* -- output pv stream in TRACKS format

*kfr* -- frequency (in Hz) of the highest-frequency track

*kamp* -- amplitude of the highest-frequency track

*fin* -- input pv stream in TRACKS format.

*kscal* -- amplitude scaling of output.

## Examples

Here is an example of the `trhighest` opcode. It uses the file `trhighest.csd` [examples/trhighest.csd].

### Example 947. Example of the `trhighest` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# trigger

`trigger` — Informs when a krate signal crosses a threshold.

## Description

Informs when a krate signal crosses a threshold.

## Syntax

```
kout trigger ksig, kthreshold, kmode
```

## Performance

*ksig* -- input signal

*kthreshold* -- trigger threshold

*kmode* -- can be 0 , 1 or 2

Normally *trigger* outputs zeroes: only each time *ksig* crosses *kthreshold* *trigger* outputs a 1. There are three modes of using *ktrig*:

- *kmode* = 0 - (down-up) *ktrig* outputs a 1 when current value of *ksig* is higher than *kthreshold*, while old value of *ksig* was equal to or lower than *kthreshold*.
- *kmode* = 1 - (up-down) *ktrig* outputs a 1 when current value of *ksig* is lower than *kthreshold* while old value of *ksig* was equal or higher than *kthreshold*.
- *kmode* = 2 - (both) *ktrig* outputs a 1 in both the two previous cases.

## Examples

Here is an example of the trigger opcode. It uses the file *trigger.csd* [examples/trigger.csd].

### Example 948. Example of the trigger opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# trigseq

trigseq — Accepts a trigger signal as input and outputs a group of values.

## Description

Accepts a trigger signal as input and outputs a group of values.

## Syntax

```
trigseq ktrig_in, kstart, kloop, kinitndx, kfn_values, kout1 [, kout2] [...]
```

## Performance

*ktrig\_in* -- input trigger signal

*kstart* -- start index of looped section

*kloop* -- end index of looped section

*kinitndx* -- initial index

### Note

Although *kinitndx* is listed as k-rate, it is in fact accessed only at init-time. So if you are using a k-rate argument, it must be assigned with *init*.

*kfn\_values* -- number of a table containing a sequence of groups of values

*kout1* -- output values

*kout2*, ... (optional) -- more output values

This opcode handles timed-sequences of groups of values stored into a table.

*trigseq* accepts a trigger signal (*ktrig\_in*) as input and outputs group of values (contained in the *kfn\_values* table) each time *ktrig\_in* assumes a non-zero value. Each time a group of values is triggered, table pointer is advanced of a number of positions corresponding to the number of group-elements, in order to point to the next group of values. The number of elements of groups is determined by the number of *koutX* arguments.

It is possible to start the sequence from a value different than the first, by assigning to *kinitndx* an index different than zero (which corresponds to the first value of the table). Normally the sequence is looped, and the start and end of loop can be adjusted by modifying *kstart* and *kloop* arguments. User must be sure that values of these arguments (as well as *kinitndx*) correspond to valid table numbers, otherwise Csound will crash because no range-checking is implemented.

It is possible to disable loop (one-shot mode) by assigning the same value both to *kstart* and *kloop* arguments. In this case, the last read element will be the one corresponding to the value of such arguments. Table can be read backward by assigning a negative *kloop* value.

*trigseq* is designed to be used together with *seqtime* or *trigger* opcodes.

## Examples

Here is an example of the trigseq opcode. It uses the file *trigseq.csd* [examples/trigseq.csd].

### **Example 949. Example of the trigseq opcode.**

# trirand

trirand — Triangular distribution random number generator

## Description

Triangular distribution random number generator. This is an x-class noise generator.

## Syntax

```
ares trirand krang  
  
ires trirand krang  
  
kres trirand krang
```

## Performance

*krange* -- the range of the random numbers (-*krange* to +*krange*).

For more detailed explanation of these distributions, see:

1. C. Dodge - T.A. Jerse 1985. Computer music. Schirmer books. pp.265 - 286
2. D. Lorrain. A panoply of stochastic cannons. In C. Roads, ed. 1989. Music machine . Cambridge, Massachusetts: MIT press, pp. 351 - 379.

## Examples

Here is an example of the trirand opcode. It uses the file *trirand.csd* [examples/trirand.csd].

# trlowest

`trlowest` — Extracts the lowest-frequency track from a streaming track input signal.

## Description

The `trlowest` opcode takes an input containing TRACKS pv streaming signals (as generated, for instance by `partials`) and outputs only the lowest track. In addition it outputs two k-rate signals, corresponding to the frequency and amplitude of the lowest track signal.

## Syntax

```
fsig, kfr, kamp trlowest fin1, kscal
```

## Performance

*fsig* -- output pv stream in TRACKS format

*kfr* -- frequency (in Hz) of the lowest-frequency track

*kamp* -- amplitude of the lowest-frequency track

*fin* -- input pv stream in TRACKS format.

*kscal* -- amplitude scaling of output.

## Examples

Here is an example of the `trlowest` opcode. It uses the file `trlowest.csd` [examples/trlowest.csd].

### Example 951. Example of the `trlowest` opcode.

# trmix

trmix — Streaming partial track mixing.

## Description

The *trmix* opcode takes two inputs containing TRACKS pv streaming signals (as generated, for instance by *partials*) and mixes them into a single TRACKS stream. Tracks will be mixed up to the available space (defined by the original number of FFT bins in the analysed signals). If the sum of the input tracks exceeds this space, the higher-ordered tracks in the second input will be pruned.

## Syntax

```
fsig trmix fin1, fin2
```

## Performance

*fsig* -- output pv stream in TRACKS format

*fin1* -- first input pv stream in TRACKS format.

*fin2* -- second input pv stream in TRACKS format

## Examples

Here is an example of the *trmix* opcode. It uses the file *trmix.csd* [examples/trmix.csd].

### Example 952. Example of the trmix opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# trscale

trscale — Streaming partial track frequency scaling.

## Description

The *trscale* opcode takes an input containing a TRACKS pv streaming signal (as generated, for instance by *partials*) and scales all frequencies by a k-rate amount. It can also, optionally, scale the gain of the signal by a k-rate amount (default 1). The result is pitch shifting of the input tracks.

## Syntax

```
fsig trscale fin, kpitch[, kgain]
```

## Performance

*fsig* -- output pv stream in TRACKS format

*fin* -- input pv stream in TRACKS format

*kpitch* -- frequency scaling

*kgain* -- amplitude scaling (default 1)

## Examples

Here is an example of the trscale opcode. It uses the file *trscale.csd* [examples/trscale.csd].

### Example 953. Example of the trscale opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# trshift

trshift — Streaming partial track frequency scaling.

## Description

The *trshift* opcode takes an input containing a TRACKS pv streaming signal (as generated, for instance by *partials*) and shifts all frequencies by a k-rate frequency. It can also, optionally, scale the gain of the signal by a k-rate amount (default 1). The result is frequency shifting of the input tracks.

## Syntax

```
fsig trshift fin, kpshift[, kgain]
```

## Performance

*fsig* -- output pv stream in TRACKS format

*fin* -- input pv stream in TRACKS format

*kshift* -- frequency shift in Hz

*kgain* -- amplitude scaling (default 1)

## Examples

Here is an example of the trshift opcode. It uses the file *trshift.csd* [examples/trshift.csd].

### Example 954. Example of the trshift opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# trssplit

trssplit — Streaming partial track frequency splitting.

## Description

The *trssplit* opcode takes an input containing a TRACKS pv streaming signal (as generated, for instance by *partials*) and splits it into two signals according to a k-rate frequency 'split point'. The first output will contain all tracks up from 0Hz to the split frequency and the second will contain the tracks from the split frequency up to the Nyquist. It can also, optionally, scale the gain of the output signals by a k-rate amount (default 1). The result is two output signals containing only part of the original spectrum.

## Syntax

```
fsiglow, fsighi trssplit fin, ksplit[, kgainlow, kgainhigh]
```

## Performance

*fsiglow* -- output pv stream in TRACKS format containing the tracks below the split point.

*fsighi* -- output pv stream in TRACKS format containing the tracks above and including the split point.

*fin* -- input pv stream in TRACKS format

*ksplit* -- frequency split point in Hz

*kgainlow, kgainhigh* -- amplitude scaling of each one of the outputs (default 1).

## Examples

Here is an example of the trssplit opcode. It uses the file *trssplit.csd* [examples/trssplit.csd].

### Example 955. Example of the trssplit opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# turnoff

turnoff — Enables an instrument to turn itself off or to turn an instance of another instrument off.

## Description

Enables an instrument to turn itself off or to turn an instance of another instrument off.

## Syntax

```
turnoff  
  
turnoff inst  
  
turnoff knst
```

## Initialization

### Initialization

*inst* -- when used with an i-time parameter, this is the instance handle of an instrument to be turned off (obtained from the nstance opcode).

*turnoff* -- with no parameters this p-time statement enables an instrument to turn itself off. Whether of finite duration or “held”, the note currently being performed by this instrument is immediately removed from the active note list. No other notes are affected.

*kinst* -- when used with an k-time parameter, this is the instance handle of an instrument to be turned off (obtained from the nstance opcode).

## Examples

The following example uses the turnoff opcode. It will cause a note to terminate when a control signal passes a certain threshold (here the Nyquist frequency). It uses the file *turnoff.csd* [examples/turnoff.csd].

### Example 956. Example of the turnoff opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

## See Also

*ihold, turnoff2, turnon*

# turnoff2

turnoff2 — Turn off instance(s) of other instruments at performance time.

## Description

Turn off instance(s) of other instruments at performance time.

## Syntax

```
turnoff2 kinsno, kmode, krelease
```

## Performance

*kinsno* -- instrument to be turned off (can be fractional) if zero or negative, no instrument is turned off

*kmode* -- sum of the following values:

- 0, 1, or 2: turn off all instances (0), oldest only (1), or newest only (2)
- 4: only turn off notes with exactly matching (fractional) instrument number, rather than ignoring fractional part
- 8: only turn off notes with indefinite duration ( $p3 < 0$  or MIDI)

*krelease* -- if non-zero, the turned off instances are allowed to release, otherwise are deactivated immediately (possibly resulting in clicks)

### Note

As a rule of thumb, you should turn off instruments with a higher instrument number than the one where turnoff is called, as doing otherwise might cause initialization issues.

## Examples

The following example uses the turnoff2 opcode, s written by Lou Cohen..

### Example 957. Example of the turnoff2 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## turnon

turnon — Activate an instrument for an indefinite time.

## Description

Activate an instrument for an indefinite time.

## Syntax

```
turnon insnum [, itime]
```

## Initialization

*insnum* -- instrument number to be activated

*itime* (optional, default=0) -- delay, in seconds, after which instrument *insnum* will be activated. Default is 0.

## Performance

*turnon* activates instrument *insnum* after a delay of *itime* seconds, or immediately if *itime* is not specified. Instrument is active until explicitly turned off. (See *turnoff*.)

## See Also

*turnoff*, *turnoff2*

# unirand

unirand — Uniform distribution random number generator (positive values only).

## Description

Uniform distribution random number generator (positive values only). This is an x-class noise generator.

## Syntax

```
ares unirand krang  
  
ires unirand krang  
  
kres unirand krang
```

## Performance

*krange* -- the range of the random numbers (0 - *krange*).

For more detailed explanation of these distributions, see:

1. C. Dodge - T.A. Jerse 1985. Computer music. Schirmer books. pp.265 - 286
2. D. Lorrain. A panoply of stochastic cannons. In C. Roads, ed. 1989. Music machine . Cambridge, Massachusetts: MIT press, pp. 351 - 379.

## Examples

Here is an example of the unirand opcode. It uses the file *unirand.csd* [examples/unirand.csd].

### Example 958. Example of the unirand opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# until

until — A syntactic looping construction.

## Description

A syntactic looping construction.

## Syntax

```
until condition do  
... od
```

## Performance

The statements between the *do* and *od* form the body of a loop which is obeyed until the conditional becomes true.

## Examples

Here is an example of the until construction. It uses the file *until.csd* [examples/until.csd].

### Example 959. Example of the until opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# upsamp

upsamp — Modify a signal by up-sampling.

## Description

Modify a signal by up-sampling.

## Syntax

```
ares upsamp ksig
```

## Performance

*upsamp* converts a control signal to an audio signal. It does it by simple repetition of the kval. *upsamp* is a slightly more efficient form of the assignment, *asig = ksig*.

## Examples

Here is an example of the *upsamp* opcode. It uses the file *upsamp.csd* [examples/upsamp.csd].

### Example 960. Example of the upsamp opcode.

# urandom

urandom — truly random opcodes with controllable range.

## Description

Truly random opcodes with controllable range. These units are for Unix-like systems only and use /dev/urandom to construct Csound random values

## Syntax

```
ax urandom [imin, imax]  
  
ix urandom [imin, imax]  
  
kx urandom [imin, imax]
```

## Initialization

*ix* -- i-rate output value.

*imin* -- minimum value of range; defaults to -1.

*imax* -- maximum value of range; defaults to +1.

### Notes

The algorithm produces  $2^{64}$  different possible values which are scaled to fit the range requested. The randomness comes from the usual Linux/OSX /dev/urandom method, and there is no guarantee that it will be truly random, but there is a good chance. It does not show any cycles.

## Performance

*ax* -- a-rate output value.

*kx* -- k-rate output value.

## Examples

Here is an example of the urandom opcode at a-rate. It uses the file *urandom.csd* [examples/urandom.csd].

### Example 961. An example of the urandom opcode at a-rate.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# urd

urd — A discrete user-defined-distribution random generator that can be used as a function.

## Description

A discrete user-defined-distribution random generator that can be used as a function.

## Syntax

```
aout = urd(ktableNum)  
  
iout = urd(itableNum)  
  
kout = urd(ktableNum)
```

## Initialization

*itableNum* -- number of table containing the random-distribution function. Such table is generated by the user. See GEN40, GEN41, and GEN42. The table length does not need to be a power of 2

## Performance

*ktableNum* -- number of table containing the random-distribution function. Such table is generated by the user. See GEN40, GEN41, and GEN42. The table length does not need to be a power of 2

*urd* is the same opcode as *duserrnd*, but can be used in function fashion.

For a tutorial about random distribution histograms and functions see:

- D. Lorrain. "A panoply of stochastic cannons". In C. Roads, ed. 1989. Music machine. Cambridge, Massachusetts: MIT press, pp. 351 - 379.

## Examples

Here is an example of the *urd* opcode. It uses the file *urd.csd* [examples/urd.csd].

### Example 963. Example of the **urd** opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# vactrol

vactrol — Envelope follower unit generator.

## Description

Envelope follower unit generator emulating a Perkin Elmer Vactrol VTL5C3/2.

## Syntax

```
ares vactrol asig [iup, idown]
```

## Initialisation

*iup* -- The rise time of the filter, which defaults to 20,

*idown* -- The fall time of the filter, which defaults to 3000,

## Performance

*asig* -- The signal from which to extract the envelope.

## Examples

Here is an example of the vactrol opcode. It uses the file *vactrol.csd* [examples/vactrol.csd].

### Example 964. Example of the vactrol opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# vadd

vadd — Adds a scalar value to a vector in a table.

## Description

Adds a scalar value to a vector in a table.

## Syntax

```
vadd ifn, kval, kelements [, kdstoffset] [, kverbose]
```

## Initialization

*ifn* - number of the table hosting the vectorial signal to be processed

## Performance

*kval* - scalar value to be added

*kelements* - number of elements of the vector

*kdstoffset* - index offset for the destination table (Optional, default=0)

*kverbose* - Selects whether or not warnings are printed (Optional, default=0)

*vadd* adds the value of *kval* to each element of the vector contained in the table *ifn*, starting from table index *kdstoffset*. This enables you to process a specific section of a table by specifying the offset and the number of elements to be processed. Offset is counted starting from 0, so if no offset is specified (or set to 0), the table will be modified from the beginning.

Note that this opcode runs at k-rate so the value of *kval* is added every control period. Use with care or you will end up with very large numbers (or use *vadd\_i*).

These opcodes (*vadd*, *vmult*, *vpow* and *vexp*) perform numeric operations between a vectorial control signal (hosted by the table *ifn*), and a scalar signal (*kval*). Result is a new vector that overrides old values of *ifn*. All these opcodes work at k-rate.

Negative values for *kdstoffset* are valid. Elements from the vector that are outside the table, will be discarded, and they will not wrap around the table.

If the optional *kverbose* argument is different to 0, the opcode will print warning messages every k-pass if table lengths are exceeded.

In all these opcodes, the resulting vectors are stored in *ifn*, overriding the initial vectors. If you want to keep initial vector, use *vcopy* or *vcopy\_i* to copy it in another table. All these operators are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2*, etc. They can also be useful in conjunction with the spectral opcodes *pvsftw* and *pvsftr*.

### Note

Please note that the *elements* argument has changed in version 5.03 from i-rate to k-rate. This will change the opcode's behavior in the unusual cases where the i-rate variable *iele-*

ments is changed inside the instrument, for example in:

```
instr 1
ielements = 10
ielements = 20
vadd 1, 1, ielements
vadd 2, 1, ielements
turnoff
endin
```

## Examples

Here is an example of the vadd opcode. It uses the file *vadd.csd* [examples/vadd.csd].

### Example 965. Example of the vadd opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## vadd\_i

vadd\_i — Adds a scalar value to a vector in a table.

## Description

Adds a scalar value to a vector in a table.

## Syntax

```
vadd_i ifn, ival, ielements [, idstoffset]
```

## Initialization

*ifn* - number of the table hosting the vectorial signal to be processed

*ielements* - number of elements of the vector

*ival* - scalar value to be added

*idstoffset* - index offset for the destination table

## Performance

*vadd\_i* adds the value of *ival* to each element of the vector contained in the table *ifn*, starting from table index *idstoffset*. This enables you to process a specific section of a table by specifying the offset and the number of elements to be processed. Offset is counted starting from 0, so if no offset is specified (or set to 0), the table will be modified from the beginning.

This opcode runs only on initialization, there is a k-rate version of this opcode called *vadd*.

Negative values for *idstoffset* are valid. Elements from the vector that are outside the table, will be discarded, and they will not wrap around the table.

In all these opcodes, the resulting vectors are stored in *ifn*, overriding the initial vectors. If you want to keep initial vector, use *vcopy* or *vcopy\_i* to copy it in another table. All these operators are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2*, etc. They can also be useful in conjunction with the spectral opcodes *pvsftw* and *pvsftr*.

## Examples

# vaddv

vaddv — Performs addition between two vectorial control signals.

## Description

Performs addition between two vectorial control signals.

## Syntax

```
vaddv ifn1, ifn2, kelements [, kdstoffset] [, ksrcoffset] [,kverbose]
```

## Initialization

*ifn1* - number of the table hosting the first vector to be processed

*ifn2* - number of the table hosting the second vector to be processed

## Performance

*kelements* - number of elements of the two vectors

*kdstoffset* - index offset for the destination (*ifn1*) table (Default=0)

*ksrcoffset* - index offset for the source (*ifn2*) table (Default=0)

*kverbose* - Selects whether or not warnings are printed (Default=0)

*vaddv* adds two vectorial control signals, that is, each element of the first vector is processed (only) with the corresponding element of the other vector. Each vectorial signal is hosted by a table (*ifn1* and *ifn2*). The number of elements contained in both vectors must be the same.

The result is a new vectorial control signal that overrides old values of *ifn1*. If you want to keep the old *ifn1* vector, use *vcopy\_ipcode* to copy it in another table. You can use *kdstoffset* and *ksrcoffset* to specify vectors in any location of the tables.

Negative values for *kdstoffset* and *ksrcoffset* are acceptable. If *kdstoffset* is negative, the out of range section of the vector will be discarded. If *ksrcoffset* is negative, the out of range elements will be assumed to be 0 (i.e. the destination elements will not be changed). If elements for the destination vector are beyond the size of the table (including guard point), these elements are discarded (i.e. elements do not wrap around the tables). If elements for the source vector are beyond the table length, these elements are taken as 0 (i.e. the destination vector will not be changed for these elements).

## Warning

Using the same table as source and destination table in versions earlier than 5.04, might produce unexpected behavior, so use with care.

This opcode works at k-rate (this means that every k-pass the vectors are added). There's an i-rate version of this opcode called *vaddv\_i*.

## Note

Please note that the *elements* argument has changed in version 5.03 from i-rate to k-rate. This will change the opcode's behavior in the unusual cases where the i-rate variable *ielements* is changed inside the instrument, for example in:

```
instr 1
ielements =      10
ielements =      20
ielements =      2, 1, ielements
turnoff
endin
```

All these operators (*vaddv*, *vsubv*, *vmultv*, *vdivv*, *vpowv*, *vexpv*, *vcopy* and *vmap*) are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2* etc.

## Examples

Here is an example of the *vaddv* opcode. It uses the file *vaddv.csd* [examples/vaddv.csd].

### Example 967. Example of the vaddv opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## vaddv\_i

vaddv\_i — Performs addition between two vectorial control signals at init time.

## Description

Performs addition between two vectorial control signals at init time.

## Syntax

```
vaddv_i ifn1, ifn2, ielements [, idstoffset] [, isrcoffset]
```

## Initialization

*ifn1* - number of the table hosting the first vector to be processed

*ifn2* - number of the table hosting the second vector to be processed

*ielements* - number of elements of the two vectors

*idstoffset* - index offset for the destination (ifn1) table (Default=0)

*isrcoffset* - index offset for the source (ifn2) table (Default=0)

## Performance

*vaddv\_i* adds two vectorial control signals, that is, each element of the first vector is processed (only) with the corresponding element of the other vector. Each vectorial signal is hosted by a table (ifn1 and ifn2). The number of elements contained in both vectors must be the same.

The result is a new vectorial control signal that overrides old values of ifn1. If you want to keep the old ifn1 vector, use *vcopy\_i* opcode to copy it in another table. You can use *idstoffset* and *isrcoffset* to specify vectors in any location of the tables.

Negative values for *idstoffset* and *isrcoffset* are acceptable. If *idstoffset* is negative, the out of range section of the vector will be discarded. If *isrcoffset* is negative, the out of range elements will be assumed to be 0 (i.e. the destination elements will not be changed). If elements for the destination vector are beyond the size of the table (including guard point), these elements are discarded (i.e. elements do not wrap around the tables). If elements for the source vector are beyond the table length, these elements are taken as 0 (i.e. the destination vector will not be changed for these elements).

### Warning

Using the same table as source and destination table in versions earlier than 5.04, might produce unexpected behavior, so use with care.

This opcode works at init time. There's an k-rate version of this opcode called *vaddv*.

All these operators (*vaddv\_i*, *vsubv\_i*, *vmultv\_i*, *vdivv\_i*, *vpowv\_i*, *vexpv\_i*, *vcopy* and *vmap*) are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2* etc.

# vaget

vaget — Access values of the current buffer of an a-rate variable by indexing.

## Description

Access values of the current buffer of an a-rate variable by indexing. Useful for doing sample-by-sample manipulation at k-rate without using setksmps 1.

### Note

Because this opcode does not do any bounds checking, the user must be careful not to try to read values past ksmpls (the size of a buffer for an a-rate variable) by using index values greater than ksmpls.

### Note

In Csound6 this opcode does do bounds checking.

## Syntax

*kval* **vaget** *kndx*, *avar*

## Performance

*kval* - value read from *avar*

*kndx* - index of the sample to read from the current buffer of the given *avar* variable

*avar* - a-rate variable to read from

## Examples

Here is an example of the *vaget* opcode. It uses the file *vaget.csd* [examples/vaget.csd].

### Example 968. Example of the *vaget* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# valpass

valpass — Variably reverberates an input signal with a flat frequency response.

## Description

Variably reverberates an input signal with a flat frequency response.

## Syntax

```
ares valpass asig, krvt, xlpt, imaxlpt [, iskip] [, insmps]
```

## Initialization

*imaxlpt* -- maximum loop time for *klpt*

*iskip* (optional, default=0) -- initial disposition of delay-loop data space (cf. *reson*). The default value is 0.

*insmps* (optional, default=0) -- delay amount, as a number of samples.

## Performance

*krvt* -- the reverberation time (defined as the time in seconds for a signal to decay to 1/1000, or 60dB down from its original amplitude).

*xlpt* -- variable loop time in seconds, same as *ilpt* in *comb*. Loop time can be as large as *imaxlpt*.

This filter reiterates input with an echo density determined by loop time *xlpt*. The attenuation rate is independent and is determined by *krvt*, the reverberation time (defined as the time in seconds for a signal to decay to 1/1000, or 60dB down from its original amplitude). Its output will begin to appear immediately.

## Examples

Here is an example of the valpass opcode. It uses the file *valpass.csd* [examples/valpass.csd].

### Example 969. Example of the valpass opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac ;;;realtime audio out
;-iadc ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime ouput leave only the line below:
;-o valpass.wav -W ;;; for file output any platform
</CsOptions>

# vaset

vaset — Write value of into the current buffer of an a-rate variable by index.

## Description

Write values into the current buffer of an a-rate variable at the given index. Useful for doing sample-by-sample manipulation at k-rate without using setksmps 1.

### Note

Because this opcode does not do any bounds checking, the user must be careful not to try to write values past ksmmps (the size of a buffer for an a-rate variable) by using index values greater than ksmmps.

### Note

In Csound6 this opcode does do bounds checking.

## Syntax

```
vaset kval, kndx, avar
```

## Performance

*kval* - value to write into *avar*

*kndx* - index of the sample to write to the current buffer of the given *avar* variable

*avar* - a-rate variable to write to

## Examples

Here is an example of the vaset opcode. It uses the file *vaset.csd* [examples/vaset.csd].

### Example 971. Example of the vaset opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# vbap

`vbap` — Distributes an audio signal among many channels.

## Description

Distributes an audio signal among many channels, up to 64 in the first form, arbitrary in the second.

## Syntax

```
ar1[, ar2...] vbap asig, kazim [,  
kelev] [, kspread] [, ilayout]
```

```
array[] vbap asig, kazim [,  
kelev] [, kspread] [, ilayout]
```

## Initialization

*ilayout* -- index of the speaker layout in the range 0-99, corresponding to a call to *vbaplsinit*.

## Performance

*asig* -- audio signal to be panned

*kazim* -- azimuth angle of the virtual source

*kelev* (optional) -- elevation angle of the virtual source

*kspread* (optional) -- spreading of the virtual source (range 0 - 100). If value is zero, conventional amplitude panning is used. When *kspread* is increased, the number of loudspeakers used in panning increases. If value is 100, the sound is applied to all loudspeakers.

*vbap* takes an input signal, *asig* and distributes it among the outputs, according to the controls *kazim* and *kelev*, and the configured loudspeaker placement. If *idim* = 2, *kelev* is set to zero. The distribution is performed using Vector Base Amplitude Panning (VBAP - See reference). VBAP distributes the signal using loudspeaker data configured with *vbaplsinit*. The signal is applied to, at most, two loudspeakers in 2-D loudspeaker configurations, and three loudspeakers in 3-D loudspeaker configurations. If the virtual source is panned outside the region spanned by loudspeakers, the nearest loudspeakers are used in panning.

### Warning

Please note that all *vbap* panning opcodes require the *vbap* system to be initialized using *vbaplsinit*.

## Examples

See the entry for *vbap8* for an example of usage of the *vbap* opcodes.

## Reference

Ville Pulkki: “Virtual Sound Source Positioning Using Vector Base Amplitude Panning” *Journal of the Audio Engineering Society*, 1997 June, Vol. 45/6, p. 456.

## Examples

Here is an example of the vbap opcode. It uses the file *vbap.csd* [examples/vbap.csd].

### Example 972. Example of the vbap opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac ;;;realtime audio out
;-iadc ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime output leave only the line below:
;-o vbap.wav -W ;; for file output any platform
</CsOptions>
<CsInstruments>

sr = 44100
ksmps = 32
nchnls = 4 ;quad
0dbfs = 1

vbaplsinit 2, 4, 0, 90, 180, 270

instr 1

asig diskin2 "beats.wav", 1, 0, 1
kaz line 0, p3, p4
a1,a2,a3,a4 vbap asig, 180, 100, kaz
    prints "spread of source = %d\n", 1, kaz

New in Csound Version 5.17.13.

Array version new in Csound Version 6.01.

# vbapmove

**vbapmove** — Distributes an audio signal among many channels with moving virtual sources.

## Description

Distributes an audio signal among upto 64 channels with moving virtual sources.

## Syntax

```
ar1[, ar2...] vbapmove asig, idur, ispread, ifldnum, ifld1 \
[, ifld2] [...]
```

```
aarray[] vbapmove asig, idur, ispread, ifldnum, ifld1 \
[, ifld2] [...]
```

## Initialization

*idur* -- the duration over which the movement takes place.

*ispread* -- spreading of the virtual source (range 0 - 100). If value is zero, conventional amplitude panning is used. When *ispread* is increased, the number of loudspeakers used in panning increases. If value is 100, the sound is applied to all loudspeakers.

*ifldnum* -- number of fields (absolute value must be 2 or larger). If *ifldnum* is positive, the virtual source movement is a polyline specified by given directions. Each transition is performed in an equal time interval. If *ifldnum* is negative, specified angular velocities are applied to the virtual source during specified relative time intervals (see below).

*ifld1*, *ifld2*, ... -- azimuth angles or angular velocities, and relative durations of movement phases (see below).

## Performance

*asig* -- audio signal to be panned

*vbapmove* allows the use of moving virtual sources. If *ifldnum* is positive, the fields represent directions of virtual sources and equal times, *iazi1*, [*iele1*,] *iazi2*, [*iele2*,], etc. The position of the virtual source is interpolated between directions starting from the first direction and ending at the last. Each interval is interpolated in time that is fraction *total\_time* / *number\_of\_intervals* of the duration of the sound event.

If *ifldnum* is negative, the fields represent angular velocities and equal times. The first field is, however, the starting direction, *iazi1*, [*iele1*,] *iazi\_vel1*, [*iele\_vel1*,] *iazi\_vel2*, [*iele\_vel2*,] .... Each velocity is applied to the note that is fraction *total\_time* / *number\_of\_velocities* of the duration of the sound event. If the elevation of the virtual source becomes greater than 90 degrees or less than 0 degrees, the polarity of angular velocity is changed. Thus the elevational angular velocity produces a virtual source that moves up and down between 0 and 90 degrees.

### Warning

Please note that all *vbap* panning opcodes require the *vbap* system to be initialized using *vbaplinit*.

## Examples

See the entry for *vbap8move* for an example of usage of the *vbapXmove* opcodes.

## Reference

Array outputs new in Csound Version 6.01

# vbapg

vbapg — Calculates the gains for a sound location between multiple channels.

## Description

Calculates the gains for a sound location for up to 64.

## Syntax

```
k1[, k2...] vbapg kazim [,kelev] [, ksspread] [, ilayout]
```

```
karray[] vbapg kazim [,kelev] [, ksspread] [, ilayout]
```

## Initialization

*ilayout* -- index of the speaker layout in the range 0-99, corresponding to a call to *vbaplsinit*. The default value is 0.

## Performance

*kazim* -- azimuth angle of the virtual source

*kelev* (optional) -- elevation angle of the virtual source

*kspread* (optional) -- spreading of the virtual source (range 0 - 100). If value is zero, conventional amplitude panning is used. When *kspread* is increased, the number of loudspeakers used in panning increases. If value is 100, the sound is applied to all loudspeakers.

*vbapg* calculates the gains that an input signal would have between multiple speakers according to the controls *kazim* and *kelev*, and the configured loudspeaker placement *ilayout*. If *idim* = 2, *kelev* is set to zero. The distribution is performed using Vector Base Amplitude Panning (VBAP - See reference). VBAP distributes the signal using loudspeaker data configured with *vbaplsinit*. The signal is applied to, at most, two loudspeakers in 2-D loudspeaker configurations, and three loudspeakers in 3-D loudspeaker configurations. If the virtual source is panned outside the region spanned by loudspeakers, the nearest loudspeakers are used in panning.

### Warning

Please note that all *vbap* panning opcodes require the *vbap* system to be initialized using *vbaplsinit*.

Array outputs new in Csound Version 6.01

# vbap16

`vbap16` — Distributes an audio signal among 16 channels.

## Description

Distributes an audio signal among 16 channels.

## Syntax

```
ar1, ..., ar16 vbap16 asig, kazim [, kelev] [, kspread]
```

## Performance

*asig* -- audio signal to be panned

*kazim* -- azimuth angle of the virtual source

*kelev* (optional) -- elevation angle of the virtual source

*kspread* (optional) -- spreading of the virtual source (range 0 - 100). If value is zero, conventional amplitude panning is used. When *kspread* is increased, the number of loudspeakers used in panning increases. If value is 100, the sound is applied to all loudspeakers.

*vbap16* takes an input signal, *asig*, and distribute it among 16 outputs, according to the controls *kazim* and *kelev*, and the configured loudspeaker placement. If *idim* = 2, *kelev* is set to zero. The distribution is performed using Vector Base Amplitude Panning (VBAP - See reference). VBAP distributes the signal using loudspeaker data configured with *vbaplsinit*. The signal is applied to, at most, two loudspeakers in 2-D loudspeaker configurations, and three loudspeakers in 3-D loudspeaker configurations. If the virtual source is panned outside the region spanned by loudspeakers, the nearest loudspeakers are used in panning.

### Warning

Please note that all *vbap* panning opcodes require the *vbap* system to be initialized using *vbaplsinit*.

## Examples

See the entry for *vbap8* for an example of usage of the *vbap* opcodes.

# vbap16move

vbap16move — Distribute an audio signal among 16 channels with moving virtual sources.

## Description

Distribute an audio signal among 16 channels with moving virtual sources.

## Syntax

```
ar1, ..., ar16 vbap16move asig, idur, ispread, ifldnum, ifld1 \
[, ifld2] [...]
```

## Initialization

*idur* -- the duration over which the movement takes place.

*ispread* -- spreading of the virtual source (range 0 - 100). If value is zero, conventional amplitude panning is used. When *ispread* is increased, the number of loudspeakers used in panning increases. If value is 100, the sound is applied to all loudspeakers.

*ifldnum* -- number of fields (absolute value must be 2 or larger). If *ifldnum* is positive, the virtual source movement is a polyline specified by given directions. Each transition is performed in an equal time interval. If *ifldnum* is negative, specified angular velocities are applied to the virtual source during specified relative time intervals (see below).

*ifld1*, *ifld2*, ... -- azimuth angles or angular velocities, and relative durations of movement phases.

## Performance

*asig* -- audio signal to be panned

*vbap16move* allows the use of moving virtual sources. If *ifldnum* is positive, the fields represent directions of virtual sources and equal times, *iazi1*, [*iele1*], *iazi2*, [*iele2*], etc. The position of the virtual source is interpolated between directions starting from the first direction and ending at the last. Each interval is interpolated in time that is fraction *total\_time* / *number\_of\_intervals* of the duration of the sound event.

If *ifldnum* is negative, the fields represent angular velocities and equal times. The first field is, however, the starting direction, *iazi1*, [*iele1*], *iazi\_vel1*, [*iele\_vel1*], *iazi\_vel2*, [*iele\_vel2*] .... Each velocity is applied to the note that is fraction *total\_time* / *number\_of\_velocities* of the duration of the sound event. If the elevation of the virtual source becomes greater than 90 degrees or less than 0 degrees, the polarity of angular velocity is changed. Thus the elevational angular velocity produces a virtual source that moves up and down between 0 and 90 degrees.

### Warning

Please note that all *vbap* panning opcodes require the *vbap* system to be initialized using *vbapsinit*.

## Examples

See the entry for *vbap8move* for an example of usage of the *vbapXmove* opcodes.

# vbap4

`vbap4` — Distributes an audio signal among 4 channels.

## Description

Distributes an audio signal among 4 channels.

## Syntax

```
ar1, ar2, ar3, ar4 vbap4 asig, kazim [, kelev] [, kspread]
```

## Performance

*asig* -- audio signal to be panned

*kazim* -- azimuth angle of the virtual source

*kelev* (optional) -- elevation angle of the virtual source

*kspread* (optional) -- spreading of the virtual source (range 0 - 100). If value is zero, conventional amplitude panning is used. When *kspread* is increased, the number of loudspeakers used in panning increases. If value is 100, the sound is applied to all loudspeakers.

*vbap4* takes an input signal, *asig* and distributes it among 4 outputs, according to the controls *kazim* and *kelev*, and the configured loudspeaker placement. If *idim* = 2, *kelev* is set to zero. The distribution is performed using Vector Base Amplitude Panning (VBAP - See reference). VBAP distributes the signal using loudspeaker data configured with *vbaplsinit*. The signal is applied to, at most, two loudspeakers in 2-D loudspeaker configurations, and three loudspeakers in 3-D loudspeaker configurations. If the virtual source is panned outside the region spanned by loudspeakers, the nearest loudspeakers are used in panning.

### Warning

Please note that all *vbap* panning opcodes require the *vbap* system to be initialized using *vbaplsinit*.

## Examples

See the entry for *vbap8* for an example of usage of the *vbap* opcodes.

## Reference

Ville Pulkki: “Virtual Sound Source Positioning Using Vector Base Amplitude Panning” *Journal of the Audio Engineering Society*, 1997 June, Vol. 45/6, p. 456.

## Examples

Here is an example of the *vbap4* opcode. It uses the file *vbap4.csd* [examples/vbap4.csd].

### Example 976. Example of the vbap4 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac ;;;realtime audio out

# vbap4move

vbap4move — Distributes an audio signal among 4 channels with moving virtual sources.

## Description

Distributes an audio signal among 4 channels with moving virtual sources.

## Syntax

```
ar1, ar2, ar3, ar4 vbap4move asig, idur, ispread, ifldnum, ifld1 \
[, ifld2] [...]
```

## Initialization

*idur* -- the duration over which the movement takes place.

*ispread* -- spreading of the virtual source (range 0 - 100). If value is zero, conventional amplitude panning is used. When *ispread* is increased, the number of loudspeakers used in panning increases. If value is 100, the sound is applied to all loudspeakers.

*ifldnum* -- number of fields (absolute value must be 2 or larger). If *ifldnum* is positive, the virtual source movement is a polyline specified by given directions. Each transition is performed in an equal time interval. If *ifldnum* is negative, specified angular velocities are applied to the virtual source during specified relative time intervals (see below).

*ifld1*, *ifld2*, ... -- azimuth angles or angular velocities, and relative durations of movement phases (see below).

## Performance

*asig* -- audio signal to be panned

*vbap4move* allows the use of moving virtual sources. If *ifldnum* is positive, the fields represent directions of virtual sources and equal times, *iazi1*, [*iele1*,] *iazi2*, [*iele2*,], etc. The position of the virtual source is interpolated between directions starting from the first direction and ending at the last. Each interval is interpolated in time that is fraction *total\_time* / *number\_of\_intervals* of the duration of the sound event.

If *ifldnum* is negative, the fields represent angular velocities and equal times. The first field is, however, the starting direction, *iazi1*, [*iele1*,] *iazi\_vel1*, [*iele\_vel1*,] *iazi\_vel2*, [*iele\_vel2*,] .... Each velocity is applied to the note that is fraction *total\_time* / *number\_of\_velocities* of the duration of the sound event. If the elevation of the virtual source becomes greater than 90 degrees or less than 0 degrees, the polarity of angular velocity is changed. Thus the elevational angular velocity produces a virtual source that moves up and down between 0 and 90 degrees.

### Warning

Please note that all *vbap* panning opcodes require the *vbap* system to be initialized using *vbaplsinit*.

## Examples

See the entry for *vbap8move* for an example of usage of the *vbapXmove* opcodes.

## Reference

Ville Pulkki: “Virtual Sound Source Positioning Using Vector Base Amplitude Panning” *Journal of the Audio Engineering Society*, 1997 June, Vol. 45/6, p. 456.

# vbap8

`vbap8` — Distributes an audio signal among 8 channels.

## Description

Distributes an audio signal among 8 channels.

## Syntax

```
ar1, ..., ar8 vbap8 asig, kazim [, kelev] [, kspread]
```

## Performance

*asig* -- audio signal to be panned

*kazim* -- azimuth angle of the virtual source

*kelev* (optional) -- elevation angle of the virtual source

*kspread* (optional) -- spreading of the virtual source (range 0 - 100). If value is zero, conventional amplitude panning is used. When *kspread* is increased, the number of loudspeakers used in panning increases. If value is 100, the sound is applied to all loudspeakers.

*vbap8* takes an input signal, *asig*, and distributes it among 8 outputs, according to the controls *kazim* and *kelev*, and the configured loudspeaker placement. If *idim* = 2, *kelev* is set to zero. The distribution is performed using Vector Base Amplitude Panning (VBAP - See reference). VBAP distributes the signal using loudspeaker data configured with *vbaplsinit*. The signal is applied to, at most, two loudspeakers in 2-D loudspeaker configurations, and three loudspeakers in 3-D loudspeaker configurations. If the virtual source is panned outside the region spanned by loudspeakers, the nearest loudspeakers are used in panning.

### Warning

Please note that all *vbap* panning opcodes require the *vbap* system to be initialized using *vbaplsinit*.

# vbap8move

vbap8move — Distributes an audio signal among 8 channels with moving virtual sources.

## Description

Distributes an audio signal among 8 channels with moving virtual sources.

## Syntax

```
ar1, ..., ar8 vbap8move asig, idur, ispread, ifldnum, ifldl \
[, ifld2] [...]
```

## Initialization

*idur* -- the duration over which the movement takes place.

*ispread* -- spreading of the virtual source (range 0 - 100). If value is zero, conventional amplitude panning is used. When *ispread* is increased, the number of loudspeakers used in panning increases. If value is 100, the sound is applied to all loudspeakers.

*ifldnum* -- number of fields (absolute value must be 2 or larger). If *ifldnum* is positive, the virtual source movement is a polyline specified by given directions. Each transition is performed in an equal time interval. If *ifldnum* is negative, specified angular velocities are applied to the virtual source during specified relative time intervals (see below).

*ifld1*, *ifld2*, ... -- azimuth angles or angular velocities, and relative durations of movement phases (see below).

## Performance

*asig* -- audio signal to be panned

*vbap8move* allows the use of moving virtual sources. If *ifldnum* is positive, the fields represent directions of virtual sources and equal times, *iazi1*, [*iele1*], *iazi2*, [*iele2*], etc. The position of the virtual source is interpolated between directions starting from the first direction and ending at the last. Each interval is interpolated in time that is fraction *total\_time* / *number\_of\_intervals* of the duration of the sound event.

If *ifldnum* is negative, the fields represent angular velocities and equal times. The first field is, however, the starting direction, *iazi1*, [*iele1*] *iazi\_vel1*, [*iele\_vel1*] *iazi\_vel2*, [*iele\_vel2*] .... Each velocity is applied to the note that is fraction *total\_time* / *number\_of\_velocities* of the duration of the sound event. If the elevation of the virtual source becomes greater than 90 degrees or less than 0 degrees, the polarity of angular velocity is changed. Thus the elevational angular velocity produces a virtual source that moves up and down between 0 and 90 degrees.

### Warning

# vbaplsinit

vbaplsinit — Configures VBAP output according to loudspeaker parameters.

## Description

Configures VBAP output according to loudspeaker parameters.

## Syntax

```
vbaplsinit idim, ilsnum [, idir1] [, idir2] [...] [, idir32]
```

## Initialization

*idim* -- dimensionality of loudspeaker array. Either 2 or 3. If the dimension has a fractional part then that is used as the index of the layout created (used in *vbap*, *vbapz* and *vbapg* only). The fractional part should be between .00 and .99.

*ilsnum* -- number of loudspeakers. In two dimensions, the number can vary from 2 to 64. In three dimensions, the number can vary from 3 and 64.

*idir1*, *idir2*, ..., *idir32* -- directions of loudspeakers. Number of directions must be less than or equal to 16. In two-dimensional loudspeaker positioning, *idirn* is the azimuth angle respective to *n*th channel. In three-dimensional loudspeaker positioning, fields are the azimuth and elevation angles of each loudspeaker consequently (*azi1*, *ele1*, *azi2*, *ele2*, etc.).

### Note

In 2 dimensions the angle between two adjacent speakers must be less than 179 degrees (170 degrees in earlier versions). This is a restriction of the algorithm.

## Performance

VBAP distributes the signal using loudspeaker data configured with *vbaplsinit*. The signal is applied to, at most, two loudspeakers in 2-D loudspeaker configurations, and three loudspeakers in 3-D loudspeaker configurations. If the virtual source is panned outside the region spanned by loudspeakers, the nearest loudspeakers are used in panning.

## Examples

Here is an example of the *vbaplsinit* opcode. It uses the file *vbaplsinit.csd* [examples/vbaplsinit.csd].

### Example 980. Example of the *vbaplsinit* opcode.

# vbapz

`vbapz` — Writes a multi-channel audio signal to a ZAK array.

## Description

Writes a multi-channel audio signal to a ZAK array.

## Syntax

```
vbapz inumchnls, istartndx, asig, kazim [, kelev] [, ksspread]
```

## Initialization

*inumchnls* -- number of channels to write to the ZA array. Must be in the range 2 - 256.

*istartndx* -- first index or position in the ZA array to use

## Performance

*asig* -- audio signal to be panned

*kazim* -- azimuth angle of the virtual source

*kelev* (optional) -- elevation angle of the virtual source

*kspread* (optional) -- spreading of the virtual source (range 0 - 100). If value is zero, conventional amplitude panning is used. When *kspread* is increased, the number of loudspeakers used in panning increases. If value is 100, the sound is applied to all loudspeakers.

The opcode *vbapz* is the multiple channel analog of the opcodes like *vbap4*, working on *inumchnls* and using a ZAK array for output.

### Warning

Please note that all *vbap* panning opcodes require the *vbap* system to be initialized using *vbaplsinit*.

## Examples

See the entry for *vbap8* for an example of usage of the *vbap* opcodes.

## Reference

Ville Pulkki: “Virtual Sound Source Positioning Using Vector Base Amplitude Panning” *Journal of the Audio Engineering Society*, 1997 June, Vol. 45/6, p. 456.

# vbapzmove

`vbapzmove` — Writes a multi-channel audio signal to a ZAK array with moving virtual sources.

## Description

Writes a multi-channel audio signal to a ZAK array with moving virtual sources.

## Syntax

```
vbapzmove inumchnls, istartndx, asig, idur, ispread, ifldnum, ifld1, \
ifld2, [...]
```

## Initialization

*inumchnls* -- number of channels to write to the ZA array. Must be in the range 2 - 256.

*istartndx* -- first index or position in the ZA array to use

*idur* -- the duration over which the movement takes place.

*ispread* -- spreading of the virtual source (range 0 - 100). If value is zero, conventional amplitude panning is used. When *ispread* is increased, the number of loudspeakers used in panning increases. If value is 100, the sound is applied to all loudspeakers.

*ifldnum* -- number of fields (absolute value must be 2 or larger). If *ifldnum* is positive, the virtual source movement is a polyline specified by given directions. Each transition is performed in an equal time interval. If *ifldnum* is negative, specified angular velocities are applied to the virtual source during specified relative time intervals (see below).

*ifld1*, *ifld2*, ... -- azimuth angles or angular velocities, and relative durations of movement phases (see below).

## Performance

*asig* -- audio signal to be panned

The opcode `vbapzmove` is the multiple channel analog of the opcodes like `vbap4move`, working on *inumchnls* and using a ZAK array for output.

### Warning

Please note that all `vbap` panning opcodes require the `vbap` system to be initialized using `vbaplsinit`.

## Examples

See the entry for `vbap8move` for an example of usage of the `vbapXmove` opcodes.

# vcella

vcella — Cellular Automata

## Description

Unidimensional Cellular Automata applied to Csound vectors

## Syntax

```
vcella ktrig, kreinit, ioutFunc, initStateFunc, \
        iRuleFunc, ielements, irulelen [, iradius]
```

## Initialization

*ioutFunc* - number of the table where the state of each cell is stored

*initStateFunc* - number of a table containing the initial states of each cell

*iRuleFunc* - number of a lookup table containing the rules

*ielements* - total number of cells

*irulelen* - total number of rules

*iradius* (optional) - radius of Cellular Automata. At present time CA radius can be 1 or 2 (1 is the default)

## Performance

*ktrig* - trigger signal. Each time it is non-zero, a new generation of cells is evaluated

*kreinit* - trigger signal. Each time it is non-zero, state of all cells is forced to be that of *initStateFunc*.

*vcella* supports unidimensional cellular automata, where the state of each cell is stored in *ioutFunc*. So *ioutFunc* is a vector containing current state of each cell. This variant vector can be used together with any other vector-based opcode, such as *adsynt*, *vmap*, *vpow* etc.

*initStateFunc* is an input vector containing the initial value of the row of cells, while *iRuleFunc* is an input vector containing the rules in the form of a lookup table. Notice that *initStateFunc* and *iRuleFunc* can be updated during the performance by means of other vector-based opcodes (for example *vcopy*) in order to force to change rules and status at performance time.

A new generation of cells is evaluated each time *ktrig* contains a non-zero value. Also the status of all cells can be forced to assume the status corresponding to the contents of *initStateFunc* each time *kreinit* contains a non-zero value.

Radius of CA algorithm can be 1 or 2 (optional *iradius* argument).

## Examples

Here is an example of the vcella opcode. It uses the file *vcella.csd* [examples/vcella.csd].

The following example uses *vcella*

### Example 981. Example of the vcella opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## VCO

vco — Implementation of a band limited, analog modeled oscillator.

## Description

Implementation of a band limited, analog modeled oscillator, based on integration of band limited impulses. *vco* can be used to simulate a variety of analog wave forms.

## Syntax

```
ares vco xamp, xcps, iwave, kpw [, ifn] [, imaxd] [, ileak] [, inyx] \
[, iphs] [, iskip]
```

## Initialization

*iwave* -- determines the waveform:

- *iwave* = 1 - sawtooth
- *iwave* = 2 - square/PWM
- *iwave* = 3 - triangle/saw/ramp

*ifn* (optional, default = 1) -- should be the table number of a stored sine wave. Must point to a valid table which contains a sine wave. Csound will report an error if this parameter is not set and table 1 doesn't exist.

*imaxd* (optional, default = 1) -- is the maximum delay time. A time of  $1/ifqc$  may be required for the PWM and triangle waveform. To bend the pitch down this value must be as large as  $1/(minimum\ frequency)$ .

*ileak* (optional, default = 0) -- if *ileak* is between zero and one ( $0 < ileak < 1$ ) then *ileak* is used as the leaky integrator value. Otherwise a leaky integrator value of .999 is used for the saw and square waves and .995 is used for the triangle wave. This can be used to “flatten” the square wave or “straighten” the saw wave at low frequencies by setting *ileak* to .99999 or a similar value. This should give a hollower sounding square wave.

*inyx* (optional, default = .5) -- this is used to determine the number of harmonics in the band limited pulse. All overtones up to  $sr * inyx$  will be used. The default gives  $sr * .5$  ( $sr/2$ ). For  $sr/4$  use *inyx* = .25. This can generate a “fatter” sound in some cases.

*iphs* (optional, default = 0) -- this is a phase value. There is an artifact (bug-like feature) in *vco* which occurs during the first half cycle of the square wave which causes the waveform to be greater in magnitude than all others. The value of *iphs* has an effect on this artifact. In particular setting *iphs* to .5 will cause the first half cycle of the square wave to resemble a small triangle wave. This may be more desirable than the large wave artifact which is the current default.

*iskip* (optional, default = 0) -- if non zero skip the initialisation of the filter. (New in Csound version 4.23f13 and 5.0)

# Performance

*kpw* -- determines either the pulse width (if *iwave* is 2) or the saw/ramp character (if *iwave* is 3). The value of *kpw* should be greater than 0 and less than 1. A value of 0.5 will generate either a square wave (if *iwave* is 2) or a triangle wave (if *iwave* is 3).

*xamp* -- determines the amplitude

*xcps* -- is the frequency of the wave in cycles per second.

# Examples

Here is an example of the vco opcode. It uses the file *vco.csd* [examples/vco.csd].

## vco2

vco2 — Implementation of a band-limited oscillator using pre-calculated tables.

## Description

vco2 is similar to vco. But the implementation uses pre-calculated tables of band-limited waveforms (see also *GEN30*) rather than integrating impulses. This opcode can be faster than vco (especially if a low control-rate is used) and also allows better sound quality. Additionally, there are more waveforms and oscillator phase can be modulated at k-rate. The disadvantage is increased memory usage. For more details about vco2 tables, see also *vco2init* and *vco2ft*.

## Syntax

```
ares vco2 kamp, kcps [, imode] [, kpw] [, kphs] [, inyx]
```

## Initialization

*imode* (optional, default=0) -- a sum of values representing the waveform and its control values.

One may use any of the following values for *imode*:

- 16: enable k-rate phase control (if set, *kphs* is a required k-rate parameter that allows phase modulation)
- 1: skip initialization

One may use exactly one of these *imode* values to select the waveform to be generated:

- 14: user defined waveform -1 (requires using the *vco2init* opcode)
- 12: triangle (no ramp, faster)
- 10: square wave (no PWM, faster)
- 8:  $4 * x * (1 - x)$  (i.e. integrated sawtooth)
- 6: pulse (not normalized)
- 4: sawtooth / triangle / ramp
- 2: square / PWM
- 0: sawtooth

The default value for *imode* is zero, which means a sawtooth wave with no k-rate phase control.

*inx* (optional, default=0.5) -- bandwidth of the generated waveform, as percentage (0 to 1) of the sample rate. The expected range is 0 to 0.5 (i.e. up to *sr/2*), other values are limited to the allowed range.

Setting *inx* to 0.25 (*sr/4*), or 0.3333 (*sr/3*) can produce a “fatter” sound in some cases, although it is

more likely to reduce quality.

## Performance

*ares* -- the output audio signal.

*kamp* -- amplitude scale. In the case of a *imode* waveform value of 6 (a pulse waveform), the actual output level can be a lot higher than this value.

*kcps* -- frequency in Hz (should be in the range *-sr/2* to *sr/2*).

*kpw* (optional) -- the pulse width of the square wave (*imode* waveform=2) or the ramp characteristics of the triangle wave (*imode* waveform=4). It is required only by these waveforms and ignored in all other cases. The expected range is 0 to 1, any other value is wrapped to the allowed range.

### Warning

*kpw* must not be an exact integer value (e.g. 0 or 1) if a sawtooth / triangle / ramp (*imode* waveform=4) is generated. In this case, the recommended range is about 0.01 to 0.99. There is no such limitation for a square/PWM waveform.

*kphs* (optional) -- oscillator phase (depending on *imode*, this can be either an optional i-rate parameter that defaults to zero or required k-rate). Similarly to *kpw*, the expected range is 0 to 1.

### Note

When a low control-rate is used, pulse width (*kpw*) and phase (*kphs*) modulation is internally converted to frequency modulation. This allows for faster processing and reduced artifacts. But in the case of very long notes and continuous fast changes in *kpw* or *kphs*, the phase may drift away from the requested value. In most cases, the phase error is at most 0.037 per hour (assuming a sample rate of 44100 Hz).

This is a problem mainly in the case of pulse width (*kpw*), where it may result in various artifacts. While future releases of *vco2* may fix such errors, the following work-arounds may also be of some help:

- Use *kpw* values only in the range 0.05 to 0.95. (There are more artifacts around integer values)
- Try to avoid modulating *kpw* by asymmetrical waveforms like a sawtooth wave. Relatively slow (<= 20 Hz) symmetrical modulation (e.g. sine or triangle), random splines (also slow), or a fixed pulse width is a lot less likely to cause synchronization problems.
- In some cases, adding random jitter (for example: random splines with an amplitude of about 0.01) to *kpw* may also fix the problem.

## Examples

Here is an example of the *vco2* opcode. It uses the file *vco2.csd* [examples/vco2.csd].

# vco2ft

`vco2ft` — Returns a table number at k-time for a given oscillator frequency and waveform.

## Description

`vco2ft` returns the function table number to be used for generating the specified waveform at a given frequency. This function table number can be used by any Csound opcode that generates a signal by reading function tables (like `oscilkt`). The tables must be calculated by `vco2init` before `vco2ft` is called and shared as Csound ftables (`ibasfn`).

## Syntax

```
kfn vco2ft kcps, iwave [, inyx]
```

## Initialization

*iwave* -- the waveform for which table number is to be selected. Allowed values are:

- 0: sawtooth
- 1:  $4 * x * (1 - x)$  (integrated sawtooth)
- 2: pulse (not normalized)
- 3: square wave
- 4: triangle

Additionally, negative *iwave* values select user defined waveforms (see also `vco2init`).

*inyx* (optional, default=0.5) -- bandwidth of the generated waveform, as percentage (0 to 1) of the sample rate. The expected range is 0 to 0.5 (i.e. up to `sr/2`), other values are limited to the allowed range.

Setting *inyx* to 0.25 (`sr/4`), or 0.3333 (`sr/3`) can produce a “fatter” sound in some cases, although it is more likely to reduce quality.

## Performance

*kfn* -- the ftable number, returned at k-rate.

*kcps* -- frequency in Hz, returned at k-rate. Zero and negative values are allowed. However, if the absolute value exceeds `sr/2` (or `sr * inyx`), the selected table will contain silence.

## Examples

See the example for the `vco2` opcode.

## See Also

# vco2ift

`vco2ift` — Returns a table number at i-time for a given oscillator frequency and waveform.

## Description

*vco2ift* is the same as *vco2ft*, but works at i-time. It is suitable for use with opcodes that expect an i-rate table number (for example, *oscili*).

## Syntax

```
ifn vco2ift icps, iwave [, inyx]
```

## Initialization

*ifn* -- the ftable number.

*icps* -- frequency in Hz. Zero and negative values are allowed. However, if the absolute value exceeds *sr/2* (or *sr \* inyx*), the selected table will contain silence.

*iwave* -- the waveform for which table number is to be selected. Allowed values are:

- 0: sawtooth
- 1:  $4 * x * (1 - x)$  (integrated sawtooth)
- 2: pulse (not normalized)
- 3: square wave
- 4: triangle

Additionally, negative *iwave* values select user defined waveforms (see also *vco2init*).

*inx* (optional, default=0.5) -- bandwidth of the generated waveform, as percentage (0 to 1) of the sample rate. The expected range is 0 to 0.5 (i.e. up to *sr/2*), other values are limited to the allowed range.

Setting *inx* to 0.25 (*sr/4*), or 0.3333 (*sr/3*) can produce a “fatter” sound in some cases, although it is more likely to reduce quality.

## Examples

Here is an example of the *vco2ift* opcode. It uses the file *vco2ift.csd* [examples/vco2ift.csd].

### Example 984. Example of the vco2ift opcode.

# vco2init

vco2init — Calculates tables for use by vco2 opcode.

## Description

*vco2init* calculates tables for use by *vco2* opcode. Optionally, it is also possible to access these tables as standard Csound function tables. In this case, *vco2ft* can be used to find the correct table number for a given oscillator frequency.

In most cases, this opcode is called from the orchestra header. Using *vco2init* in instruments is possible but not recommended. This is because replacing tables during performance can result in a Csound crash if other opcodes are accessing the tables at the same time.

Note that *vco2init* is not required for *vco2* to work (tables are automatically allocated by the first *vco2* call, if not done yet), however it can be useful in some cases:

- Pre-calculate tables at orchestra load time. This is useful to avoid generating the tables during performance, which could interrupt real-time processing.
- Share the tables as Csound ftables. By default, the tables can be accessed only by *vco2*.
- Change the default parameters of tables (e.g. size) or use an user-defined waveform specified in a function table.

## Syntax

```
ifn vco2init iwave [, ibasfn] [, ipmul] [, iminsiz] [, imaxsiz] [, isrcf]
```

## Initialization

*ifn* -- the first free ftable number after the allocated tables. If *ibasfn* was not specified, -1 is returned.

*iwave* -- sum of the following values selecting which waveforms are to be calculated:

- 16: triangle
- 8: square wave
- 4: pulse (not normalized)
- 2:  $4 * x * (1 - x)$  (integrated sawtooth)
- 1: sawtooth

Alternatively, *iwave* can be set to a negative integer that selects an user-defined waveform. This also requires the *isrcf* parameter to be specified. *vco2* can access waveform number -1. However, other user-defined waveforms are usable only with *vco2ft* or *vco2ift*.

*ibasfn* (optional, default=-1) -- ftable number from which the table set(s) can be accessed by opcodes

other than *vco2*. This is required by user defined waveforms, with the exception of -1. If this value is less than 1, it is not possible to access the tables calculated by *vco2init* as Csound function tables.

*ipmul* (optional, default=1.05) -- multiplier value for number of harmonic partials. If one table has n partials, the next one will have  $n * ipmul$  (at least  $n + 1$ ). The allowed range for *ipmul* is 1.01 to 2. Zero or negative values select the default (1.05).

*iminsiz* (optional, default=-1) -- minimum table size.

*imaxsiz* (optional, default=-1) -- maximum table size.

The actual table size is calculated by multiplying the square root of the number of harmonic partials by *iminsiz*, rounding up the result to the next power of two, and limiting this not to be greater than *imaxsiz*.

Both parameters, *iminsiz* and *imaxsiz*, must be power of two, and in the allowed range. The allowed range is 16 to 262144 for *iminsiz* to up to 16777216 for *imaxsiz*. Zero or negative values select the default settings:

- The minimum size is 128 for all waveforms except pulse (*iwave*=4). Its minimum size is 256.
- The default maximum size is usually the minimum size multiplied by 64, but not more than 16384 if possible. It is always at least the minimum size.

*isrcf* (optional, default=-1) -- source ftable number for user-defined waveforms (if *iwave* < 0). *isrcf* should point to a function table containing the waveform to be used for generating the table array. The table size is recommended to be at least *imaxsiz* points. If *iwave* is not negative (built-in waveforms are used), *isrcf* is ignored.

## Warning

The number and size of tables is not fixed. Orchestras should not depend on these parameters, as they are subject to changes between releases.

If the selected table set already exists, it is replaced. If any opcode is accessing the tables at the same time, it is very likely that a crash will occur. This is why it is recommended to use *vco2init* only in the orchestra header.

These tables should not be replaced/overwritten by GEN routines or the *ftgen* opcode. Otherwise, unpredictable behavior or a Csound crash may occur if *vco2* is used. The first free ftable after the table array(s) is returned in *ifn*.

## Examples

Here is an example of the *vco2init* opcode. It uses the file *vco2init.csd* [examples/vco2init.csd].

### Example 985. Example of the vco2init opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac ;;;realtime audio out
;-iadc ;;;uncomment -iadc if realtime audio input is needed too
```

```
; For Non-realtime output leave only the line below:  
; -o vco2init.wav -W ;; for file output any platform  
</CsOptions>  
</CsInstruments>

# vcomb

vcomb — Variably reverberates an input signal with a “colored” frequency response.

## Description

Variably reverberates an input signal with a “colored” frequency response.

## Syntax

```
ares vcomb asig, krvt, xlpt, imaxlpt [, iskip] [, insmps]
```

## Initialization

*imaxlpt* -- maximum loop time for *klpt*

*iskip* (optional, default=0) -- initial disposition of delay-loop data space (cf. *reson*). The default value is 0.

*insmps* (optional, default=0) -- delay amount, as a number of samples.

## Performance

*krvt* -- the reverberation time (defined as the time in seconds for a signal to decay to 1/1000, or 60dB down from its original amplitude).

*xlpt* -- variable loop time in seconds, same as *ilpt* in *comb*. Loop time can be as large as *imaxlpt*.

This filter reiterates input with an echo density determined by loop time *xlpt*. The attenuation rate is independent and is determined by *krvt*, the reverberation time (defined as the time in seconds for a signal to decay to 1/1000, or 60dB down from its original amplitude). Output will appear only after *ilpt* seconds.

## Examples

Here is an example of the vcomb opcode. It uses the file *vcomb.csd* [examples/vcomb.csd].

### Example 986. Example of the vcomb opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# vcopy

vcopy — Copies between two vectorial control signals

## Description

Copies between two vectorial control signals

## Syntax

```
vcopy ifn1, ifn2, kelements [, kdstoffset] [, ksrcoffset] [, kverbose]
```

## Initialization

*ifn1* - number of the table where the vectorial signal will be copied (destination)

*ifn2* - number of the table hosting the vectorial signal to be copied (source)

## Performance

*kelements* - number of elements of the vector

*kdstoffset* - index offset for the destination (*ifn1*) table (Default=0)

*ksrcoffset* - index offset for the source (*ifn2*) table (Default=0)

*kverbose* - Selects whether or not warnings are printed (Default=0)

vcopy copies *kelements* elements from *ifn2* (starting from position *ksrcoffset*) to *ifn1* (starting from position *kdstoffset*). Useful to keep old vector values, by storing them in another table.

Negative values for *kdstoffset* and *ksrcoffset* are acceptable. If *kdstoffset* is negative, the out of range section of the vector will be discarded. If *kdstoffset* is negative, the out of range elements will be assumed to be 1 (i.e. the destination elements will not be changed). If elements for the destination vector are beyond the size of the table (including guard point), these elements are discarded (i.e. elements do not wrap around the tables). If elements for the source vector are beyond the table length, these elements are taken as 1 (i.e. the destination vector will not be changed for these elements).

If the optional *kverbose* argument is different to 0, the opcode will print warning messages every k-pass if table lengths are exceeded.

### Warning

Using the same table as source and destination table in versions earlier than 5.04, might produce unexpected behavior, so use with care.

This opcode works at k-rate (this means that every k-pass the vectors are copied). There's an i-rate version of this opcode called *vcopy\_i*.

### Note

Please note that the *elements* argument has changed in version 5.03 from i-rate to k-rate.

This will change the opcode's behavior in the unusual cases where the i-rate variable *ielements* is changed inside the instrument, for example in:

```
instr 1
ielements =      10
              vadd    1, 1, ielements
ielements =      20
              vadd    2, 1, ielements
              turnoff
endin
```

All these operators (*vaddv*, *vsubv*, *vmultv*, *vdivv*, *vpowv*, *vexp*, *vcopy* and *vmap*) are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2* etc.

## Examples

Here is an example of the *vcopy* opcode. It uses the file *vcopy.csd* [examples/vcopy.csd].

### Example 987. Example of the *vcopy* opcode.

# vcopy\_i

vcopy\_i — Copies a vector from one table to another.

## Description

Copies a vector from one table to another.

## Syntax

```
vcopy_i ifn1, ifn2, ielements [,idstoffset, isrcoffset]
```

## Initialization

*ifn1* - number of the table where the vectorial signal will be copied

*ifn2* - number of the table hosting the vectorial signal to be copied

*ielements* - number of elements of the vector

*idstoffset* - index offset for destination table

*isrcoffset* - index offset for source table

## Performance

*vcopy\_i* copies *ielements* elements from *ifn2* (starting from position *isrcoffset*) to *ifn1* (starting from position *idstoffset*). Useful to keep old vector values, by storing them in another table. This opcode is exactly the same as *vcopy* but performs all the copying on the initialization pass only.

Negative values for *idstoffset* and *isrcoffset* are acceptable. If *idstoffset* is negative, the out of range section of the vector will be discarded. If *isrcoffset* is negative, the out of range elements will be assumed to be 0 (i.e. the destination elements will be set to 0). If elements for the destination vector are beyond the size of the table (including guard point), these elements are discarded (i.e. elements do not wrap around the tables). If elements for the source vector are beyond the table length, these elements are taken as 0 (i.e. the destination vector elements will be 0).

### Warning

Using the same table as source and destination table in versions earlier than 5.04, might produce unexpected behavior, so use with care.

All these operators (*vaddv*, *vsubv*, *vmultv*, *vdivv*, *vpowv*, *vexp*, *vcopy* and *vmap*) are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2* etc.

## Examples

See *vcopy* for an example.

# vdelay

vdelay — An interpolating variable time delay.

## Description

This is an interpolating variable time delay, it is not very different from the existing implementation (*deltapi*), it is only easier to use.

## Syntax

```
ares vdelay asig, adel, imaxdel [, iskip]
```

## Initialization

*imaxdel* -- Maximum value of delay in milliseconds. If *adel* gains a value greater than *imaxdel* it is folded around *imaxdel*. This should not happen.

*iskip* -- Skip initialization if present and non-zero

## Performance

With this unit generator it is possible to do Doppler effects or chorusing and flanging.

*asig* -- Input signal.

*adel* -- Current value of delay in milliseconds. Note that linear functions have no pitch change effects. Fast changing values of *adel* will cause discontinuities in the waveform resulting noise.

## Examples

Here is an example of the vdelay opcode. It uses the file *vdelay.csd* [examples/vdelay.csd].

### Example 988. Example of the vdelay opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac ;;;realtime audio out
;-iadc ;;;uncomment -iadc if realtime audio input is needed too
; For Non-realtime output leave only the line below:
;-o vdelay.wav -W ;; for file output any platform
</CsOptions>
<CsInstruments>

sr    = 44100
ksmps = 32
nchnls = 2
0dbfs = 1

instr 1
```

```
ims  = 100                                ;maximum delay time in msec
aout poscil .8, 220, 1                  ;make a signal
a2   poscil3 ims/2, 1/p3, 1            ;make an LFO
a2   = a2 + ims/2                          ;offset the LFO so that it is positive
asig vdelay aout, a2, ims             ;use the LFO to control delay time
outs asig, asig

endin
</CsInstruments>
<CsScore>
f1 0 8192 10 1 ;sine wave

i 1 0 5

e
</CsScore>
</CsoundSynthesizer>
```

Two important points here. First, the delay time must be always positive. And second, even though the delay time can be controlled in k-rate, it is not advised to do so, since sudden time changes will create clicks.

# vdelayx

vdelayx — A variable delay opcode with high quality interpolation.

## Description

A variable delay opcode with high quality interpolation.

## Syntax

```
aout vdelayx ain, adl, imd, iws [, ist]
```

## Initialization

*imd* -- max. delay time (seconds)

*iws* -- interpolation window size (see below)

*ist* (optional) -- skip initialization if not zero

## Performance

*aout* -- output audio signal

*ain* -- input audio signal

*adl* -- delay time in seconds

This opcode uses high quality (and slow) interpolation, that is much more accurate than the currently available linear and cubic interpolation. The *iws* parameter sets the number of input samples used for calculating one output sample (allowed values are any integer multiply of 4 in the range 4 - 1024); higher values mean better quality and slower speed.

## Notes

- Delay time is measured in seconds (unlike in vdelay and vdelay3), and must be a-rate.
- The minimum allowed delay is *iws*/2 samples.
- Using the same variables as input and output is allowed in these opcodes.
- In vdelayxw\*, changing the delay time has some effects on output volume:

$$a = 1 / (1 + dt)$$

where *a* is the output gain, and *dt* is the change of delay time per seconds.

- These opcodes are best used in the double-precision version of Csound.

## Examples

Here is an example of the use of the *vdelayx* opcode. It uses the file *vdelayx.csd* [examples/vdelayx.csd].

### Example 990. Example of the *vdelayx* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

</CsScore>
</CsoundSynthesizer>
```

## See Also

*vdelayxq*, *vdelayxs*, *vdelayxw*, *vdelayxwq*, *vdelayxws*

# vdelayxq

vdelayxq — A 4-channel variable delay opcode with high quality interpolation.

## Description

A 4-channel variable delay opcode with high quality interpolation.

## Syntax

```
aout1, aout2, aout3, aout4 vdelayxq ain1, ain2, ain3, ain4, adl, imd, iws [, ist]
```

## Initialization

*imd* -- max. delay time (seconds)

*iws* -- interpolation window size (see below)

*ist* (optional) -- skip initialization if not zero

## Performance

*aout1, aout2, aout3, aout4* -- output audio signals.

*ain1, ain2, ain3, ain4* -- input audio signals.

*adl* -- delay time in seconds

This opcode uses high quality (and slow) interpolation, that is much more accurate than the currently available linear and cubic interpolation. The *iws* parameter sets the number of input samples used for calculating one output sample (allowed values are any integer multiply of 4 in the range 4 - 1024); higher values mean better quality and slower speed.

The multichannel opcodes (eg. *vdelayxq*) allow delaying 2 or 4 variables at once (stereo or quad signals); this is much more efficient than using separate opcodes for each channel.

## Notes

- Delay time is measured in seconds (unlike in *vdelay* and *vdelay3*), and must be a-rate.
- The minimum allowed delay is *iws*/2 samples.
- Using the same variables as input and output is allowed in these opcodes.
- In *vdelayxw\**, changing the delay time has some effects on output volume:

$$a = 1 / (1 + dt)$$

where *a* is the output gain, and *dt* is the change of delay time per seconds.

- These opcodes are best used in the double-precision version of Csound.

## Examples

Here is an example of the vdelayxq opcode. It uses the file *vdelayxq.csd* [examples/vdelayxq.csd].

### **Example 991. Example of the vdelayxq opcode.**

```

Two important points here. First, the delay time must be always positive. And second, even though the delay time can be controlled in k-rate, it is not advised to do so, since sudden time changes will create clicks.

# vdelayxs

vdelayxs — A stereo variable delay opcode with high quality interpolation.

## Description

A stereo variable delay opcode with high quality interpolation.

## Syntax

```
aout1, aout2 vdelayxs ain1, ain2, adl, imd, iws [, ist]
```

## Initialization

*imd* -- max. delay time (seconds)

*iws* -- interpolation window size (see below)

*ist* (optional) -- skip initialization if not zero

## Performance

*aout1, aout2* -- output audio signals

*ain1, ain2* -- input audio signals

*adl* -- delay time in seconds

This opcode uses high quality (and slow) interpolation, that is much more accurate than the currently available linear and cubic interpolation. The *iws* parameter sets the number of input samples used for calculating one output sample (allowed values are any integer multiply of 4 in the range 4 - 1024); higher values mean better quality and slower speed.

The multichannel opcodes (eg. *vdelayxq*) allow delaying 2 or 4 variables at once (stereo or quad signals); this is much more efficient than using separate opcodes for each channel.

## Notes

- Delay time is measured in seconds (unlike in *vdelay* and *vdelay3*), and must be a-rate.
- The minimum allowed delay is *iws*/2 samples.
- Using the same variables as input and output is allowed in these opcodes.
- In *vdelayxw\**, changing the delay time has some effects on output volume:  
$$a = 1 / (1 + dt)$$
where *a* is the output gain, and *dt* is the change of delay time per seconds.
- These opcodes are best used in the double-precision version of Csound.

## Examples

Here is an example of the use of the `vdelayxs` opcode. It uses the file `vdelayxs.csd` [examples/`vdelayxs.csd`].

### Example 992. Example of the `vdelayxs` opcode.

# vdelayxw

vdelayxw — Variable delay opcodes with high quality interpolation.

## Description

Variable delay opcodes with high quality interpolation.

## Syntax

```
aout vdelayxw ain, adl, imd, iws [, ist]
```

## Initialization

*imd* -- max. delay time (seconds)

*iws* -- interpolation window size (see below)

*ist* (optional) -- skip initialization if not zero

## Performance

*aout* -- output audio signal

*ain* -- input audio signal

*adl* -- delay time in seconds

These opcodes use high quality (and slow) interpolation, that is much more accurate than the currently available linear and cubic interpolation. The *iws* parameter sets the number of input samples used for calculating one output sample (allowed values are any integer multiply of 4 in the range 4 - 1024); higher values mean better quality and slower speed.

The *vdelayxw* opcodes change the position of the write tap in the delay line (unlike all other delay ugens that move the read tap), and are most useful for implementing Doppler effects where the position of the listener is fixed, and the sound source is moving.

## Notes

- Delay time is measured in seconds (unlike in *vdelay* and *vdelay3*), and must be a-rate.
- The minimum allowed delay is *iws*/2 samples.
- Using the same variables as input and output is allowed in these opcodes.
- In *vdelayxw\**, changing the delay time has some effects on output volume:

$$a = 1 / (1 + dt)$$

where *a* is the output gain, and *dt* is the change of delay time per seconds.

- These opcodes are best used in the double-precision version of Csound.

## Examples

Here is an example of the use of the *vdelayxw* opcode. It uses the file *vdelayxw.csd* [examples/vdelayxw.csd].

### Example 993. Example of the *vdelayxw* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# vdelayxws

vdelayxws — Variable delay opcodes with high quality interpolation.

## Description

Variable delay opcodes with high quality interpolation.

## Syntax

```
aout1, aout2 vdelayxws ain1, ain2, adl, imd, iws [, ist]
```

## Initialization

*imd* -- max. delay time (seconds)

*iws* -- interpolation window size (see below)

*ist* (optional) -- skip initialization if not zero

## Performance

*ain1*, *ain2* -- input audio signals

*aout1*, *aout2* -- output audio signals

*adl* -- delay time in seconds

These opcodes use high quality (and slow) interpolation, that is much more accurate than the currently available linear and cubic interpolation. The *iws* parameter sets the number of input samples used for calculating one output sample (allowed values are any integer multiply of 4 in the range 4 - 1024); higher values mean better quality and slower speed.

The vdelayxw opcodes change the position of the write tap in the delay line (unlike all other delay ugens that move the read tap), and are most useful for implementing Doppler effects where the position of the listener is fixed, and the sound source is moving.

The multichannel opcodes (eg. *vdelayxq*) allow delaying 2 or 4 variables at once (stereo or quad signals); this is much more efficient than using separate opcodes for each channel.

## Notes

- Delay time is measured in seconds (unlike in vdelay and vdelay3), and must be a-rate.
- The minimum allowed delay is *iws*/2 samples.
- Using the same variables as input and output is allowed in these opcodes.
- In vdelayxw\*, changing the delay time has some effects on output volume:

$$a = 1 / (1 + dt)$$

where a is the output gain, and dt is the change of delay time per seconds.

- These opcodes are best used in the double-precision version of Csound.

# vdelayk

vdelayk — k-rate variable time delay.

## Description

Variable delay applied to a k-rate signal

## Syntax

```
kout vdelayk  ksig, kdel, imaxdel [, iskip, imode]
```

## Initialization

*imaxdel* - maximum value of delay in seconds.

*iskip* (optional) - Skip initialization if present and non zero.

*imode* (optional) - if non-zero it suppresses linear interpolation. While, normally, interpolation increases the quality of a signal, it should be suppressed if using vdelay with discrete control signals, such as, for example, trigger signals.

## Performance

*kout* - delayed output signal

*ksig* - input signal

*kdel* - delay time in seconds can be varied at k-rate

*vdelayk* is similar to *vdelay*, but works at k-rate. It is designed to delay control signals, to be used, for example, in algorithmic composition.

# vdivv

vdivv — Performs division between two vectorial control signals

## Description

Performs division between two vectorial control signals

## Syntax

```
vdivv ifn1, ifn2, kelements [, kdstoffset] [, ksrcoffset] [,kverbose]
```

## Initialization

*ifn1* - number of the table hosting the first vector to be processed

*ifn2* - number of the table hosting the second vector to be processed

## Performance

*kelements* - number of elements of the two vectors

*kdstoffset* - index offset for the destination (*ifn1*) table (Default=0)

*ksrcoffset* - index offset for the source (*ifn2*) table (Default=0)

*kverbose* - Selects whether or not warnings are printed (Default=0)

*vdivv* divides two vectorial control signals, that is, each element of *ifn1* is divided by the corresponding element of *ifn2*. Each vectorial signal is hosted by a table (*ifn1* and *ifn2*). The number of elements contained in both vectors must be the same.

The result is a new vectorial control signal that overrides old values of *ifn1*. If you want to keep the old *ifn1* vector, use *vcopy\_i* opcode to copy it in another table. You can use *kdstoffset* and *ksrcoffset* to specify vectors in any location of the tables.

Negative values for *kdstoffset* and *ksrcoffset* are acceptable. If *kdstoffset* is negative, the out of range section of the vector will be discarded. If *ksrcoffset* is negative, the out of range elements will be assumed to be 0 (i.e. the destination elements will be set to 0). If elements for the destination vector are beyond the size of the table (including guard point), these elements are discarded (i.e. elements do not wrap around the tables). If elements for the source vector are beyond the table length, these elements are taken as 0 (i.e. the destination elements will be set to 0).

If the optional *kverbose* argument is different to 0, the opcode will print warning messages every k-pass if table lengths are exceeded.

## Warning

Using the same table as source and destination table in versions earlier than 5.04, might produce unexpected behavior, so use with care.

This opcode works at k-rate (this means that every k-pass the vectors are divided). There's an i-rate ver-

sion of this opcode called *vdivv\_i*.

## Note

Please note that the *elements* argument has changed in version 5.03 from i-rate to k-rate. This will change the opcode's behavior in the unusual cases where the i-rate variable *ielements* is changed inside the instrument, for example in:

```
instr 1
ielements =      10
              vadd    1, 1, ielements
ielements =      20
              vadd    2, 1, ielements
turnoff
endin
```

All these operators (*vaddv*, *vsubv*, *vmultv*, *vdivv*, *vpowv*, *vexpv*, *vcopy* and *vmap*) are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2* etc.

## Examples

Here is an example of the *vdivv* opcode. It uses the file *vdivv.csd* [examples/vdivv.csd].

### Example 996. Example of the *vdivv* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## vdivv\_i

vdivv\_i — Performs division between two vectorial control signals at init time.

## Description

Performs division between two vectorial control signals at init time.

## Syntax

```
vdivv_i ifn1, ifn2, ielements [, idstoffset] [, isrcoffset]
```

## Initialization

*ifn1* - number of the table hosting the first vector to be processed

*ifn2* - number of the table hosting the second vector to be processed

*ielements* - number of elements of the two vectors

*idstoffset* - index offset for the destination (ifn1) table (Default=0)

*isrcoffset* - index offset for the source (ifn2) table (Default=0)

## Performance

*vdivv\_i* divides two vectorial control signals, that is, each element of ifn1 is divided by the corresponding element of ifn2. Each vectorial signal is hosted by a table (ifn1 and ifn2). The number of elements contained in both vectors must be the same.

The result is a new vectorial control signal that overrides old values of ifn1. If you want to keep the old ifn1 vector, use *vcopy\_i* opcode to copy it in another table. You can use *idstoffset* and *isrcoffset* to specify vectors in any location of the tables.

Negative values for *idstoffset* and *isrcoffset* are acceptable. If *idstoffset* is negative, the out of range section of the vector will be discarded. If *isrcoffset* is negative, the out of range elements will be assumed to be 1 (i.e. the destination elements will not be changed). If elements for the destination vector are beyond the size of the table (including guard point), these elements are discarded (i.e. elements do not wrap around the tables). If elements for the source vector are beyond the table length, these elements are taken as 1 (i.e. the destination vector will not be changed for these elements).

### Warning

Using the same table as source and destination table in versions earlier than 5.04, might produce unexpected behavior, so use with care.

This opcode works at init time. There's an k-rate version of this opcode called *vdivv*.

All these operators (*vaddv\_i*, *vsubv\_i*, *vmultv\_i*, *vdivv\_i*, *vpowv\_i*, *vexpv\_i*, *vcopy* and *vmap*) are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2* etc.

# vecdelay

`vecdelay` — Vectorial Control-rate Delay Paths

## Description

Generate a sort of 'vectorial' delay

## Syntax

```
vecdelay ifn, ifnIn, ifnDel, ielements, imaxdel [, iskip]
```

## Initialization

*ifn* - number of the table containing the output vector

*ifnIn* - number of the table containing the input vector

*ifnDel* - number of the table containing a vector whose elements contain delay values in seconds

*ielements* - number of elements of the two vectors

*imaxdel* - Maximum value of delay in seconds.

*iskip* (optional) - initial disposition of delay-loop data space (see reson). The default value is 0.

## Performance

*vecdelay* is similar to *vdelay*, but it works at k-rate and, instead of delaying a single signal, it delays a vector. *ifnIn* is the input vector of signals, *ifn* is the output vector of signals, and *ifnDel* is a vector containing delay times for each element, expressed in seconds. Elements of *ifnDel* can be updated at k-rate. Each single delay can be different from that of the other elements, and can vary at k-rate. *imaxdel* sets the maximum delay allowed for all elements of *ifnDel*.

## Initialization

*ifn* - number of the table hosting the vectorial signal to be processed

## Performance

*kval* - scalar operand to be processed

*kelements* - number of elements of the vector

*kdstoffset* - index offset for the destination table (Optional, default = 0)

*kverbose* - Selects whether or not warnings are printed (Default=0)

*vexp* rises *kval* to each element contained in a vector from table *ifn*, starting from table index *kdstoffset*. This enables you to process a specific section of a table by specifying the offset and the number of elements to be processed. Offset is counted starting from 0, so if no offset is specified (or set to 0), the table will be modified from the beginning.

Note that this opcode runs at k-rate so the value of *kval* is processed every control period. Use with care or you will end up with very large (or small) numbers (or use *vexp\_i*).

These opcodes (*vadd*, *vmult*, *vpow* and *vexp*) perform numeric operations between a vectorial control signal (hosted by the table *ifn*), and a scalar signal (*kval*). Result is a new vector that overrides old values of *ifn*. All these opcodes work at k-rate.

Negative values for *kdstoffset* are valid. Elements from the vector that are outside the table, will be discarded, and they will not wrap around the table.

If the optional *kverbose* argument is different to 0, the opcode will print warning messages every k-pass if table lengths are exceeded.

In all these opcodes, the resulting vectors are stored in *ifn*, overriding the initial vectors. If you want to keep initial vector, use *vcopy* or *vcopy\_i* to copy it in another table. All these operators are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2*, etc. They can also be useful in conjunction with the spectral opcodes *pvsftw* and *pvsftr*.

### Note

Please note that the *elements* argument has changed in version 5.03 from i-rate to k-rate. This will change the opcode's behavior in the unusual cases where the i-rate variable *iele-*

ments is changed inside the instrument, for example in:

```
instr 1
ielements = 10
ielements = 20
vadd 1, 1, ielements
vadd 2, 1, ielements
turnoff
endin
```

## Examples

Here is an example of the vexp opcode. It uses the file *vexp.csd* [examples/vexp.csd].

### Example 998. Example of the vexp opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# vexp\_i

`vexp_i` — Performs power-of operations between a vector and a scalar

## Description

Performs power-of operations between a vector and a scalar

## Syntax

```
vexp_i ifn, ival, ielements[, idstoffset]
```

## Initialization

*ifn* - number of the table hosting the vectorial signal to be processed

*ival* - scalar operand to be processed

*ielements* - number of elements of the vector

*ival* - scalar value to be added

*idstoffset* - index offset for the destination table

## Performance

`vexp_i` rises *ival* to each element contained in a vector from table *ifn*, starting from table index *idstoffset*. This enables you to process a specific section of a table by specifying the offset and the number of elements to be processed. Offset is counted starting from 0, so if no offset is specified (or set to 0), the table will be modified from the beginning.

Negative values for *idstoffset* are valid. Elements from the vector that are outside the table, will be discarded, and they will not wrap around the table.

This opcode runs only on initialization, there is a k-rate version of this opcode called `vexp`.

In all these opcodes, the resulting vectors are stored in *ifn*, overriding the initial vectors. If you want to keep initial vector, use `vcopy` or `vcopy_i` to copy it in another table. All these operators are designed to be used together with other opcodes that operate with vectorial signals such as `vcella`, `adsynt`, `adsynt2`, etc. They can also be useful in conjunction with the spectral opcodes `pvsftw` and `pvsftr`.

## Examples

Here is an example of the `vexp_i` opcode. It uses the file `vexp_i.csd` [examples/vexp\_i.csd].

### Example 999. Example of the vexp\_i opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# vexpseg

vexpseg — Vectorial envelope generator

## Description

Generate exponential vectorial segments

## Syntax

```
vexpseg ifnout, ielements, ifn1, idur1, ifn2 [, idur2, ifn3 [...]]
```

## Initialization

*ifnout* - number of table hosting output vectorial signal

*ifn1* - starting vector

*ifn2, ifn3,etc.* - vector after *idurx* seconds

*idur1* - duration in seconds of first segment.

*idur2, idur3, etc.* - duration in seconds of subsequent segments.

*ielements* - number of elements of vectors.

## Performance

These opcodes are similar to *linseg* and *expseg*, but operate with vectorial signals instead of with scalar signals.

Output is a vectorial control signal hosted by *ifnout* (that must be previously allocated), while each break-point of the envelope is actually a vector of values. All break-points must contain the same number of elements (*ielements*).

All these operators are designed to be used together with other opcodes that operate with vectorial signals such as>, *vcella*, *adsynt*, *adsynt2*, etc.

## Example

Here is an example of the vexpseg opcode. It uses the files *vexpseg.csd* [examples/vexpseg.csd].

# vexpv

`vexpv` — Performs exponential operations between two vectorial control signals

## Description

Performs exponential operations between two vectorial control signals

## Syntax

```
vexpv ifn1, ifn2, kelements [, kdstoffset] [, ksrcoffset] [,kverbose]
```

## Initialization

*ifn1* - number of the table hosting the first vector to be processed

*ifn2* - number of the table hosting the second vector to be processed

## Performance

*kelements* - number of elements of the two vectors

*kdstoffset* - index offset for the destination (*ifn1*) table (Default=0)

*ksrcoffset* - index offset for the source (*ifn2*) table (Default=0)

*kverbose* - Selects whether or not warnings are printed (Default=0)

`vexpv` elevates each element of *ifn2* to the corresponding element of *ifn1*. Each vectorial signal is hosted by a table (*ifn1* and *ifn2*). The number of elements contained in both vectors must be the same.

The result is a new vectorial control signal that overrides old values of *ifn1*. If you want to keep the old *ifn1* vector, use `vcopy_i` opcode to copy it in another table. You can use *kdstoffset* and *ksrcoffset* to specify vectors in any location of the tables.

Negative values for *kdstoffset* and *ksrcoffset* are acceptable. If *kdstoffset* is negative, the out of range section of the vector will be discarded. If *ksrcoffset* is negative, the out of range elements will be assumed to be 0 (i.e. the destination elements will be set to 1). If elements for the destination vector are beyond the size of the table (including guard point), these elements are discarded (i.e. elements do not wrap around the tables). If elements for the source vector are beyond the table length, these elements are taken as 0 (i.e. the destination elements will be set to 1).

If the optional *kverbose* argument is different to 0, the opcode will print warning messages every k-pass if table lengths are exceeded.

### Warning

Using the same table as source and destination table in versions earlier than 5.04, might produce unexpected behavior, so use with care.

This opcode works at k-rate (this means that every k-pass the vectors are processed). There's an i-rate version of this opcode called `vexpv_i`.

## Note

Please note that the *elements* argument has changed in version 5.03 from i-rate to k-rate. This will change the opcode's behavior in the unusual cases where the i-rate variable *ielements* is changed inside the instrument, for example in:

```
instr 1
ielements = 10
vadd 1, 1, ielements
ielements = 20
vadd 2, 1, ielements
turnoff
endin
```

All these operators (*vaddv*, *vsubv*, *vmultv*, *vdivv*, *vpowv*, *vexpv*, *vcopy* and *vmap*) are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2* etc.

## Examples

Here is an example of the *vexpv* opcode. It uses the file *vexpv.csd* [examples/vexpv.csd].

### Example 1001. Example of the *vexpv* opcode.

# vexpv\_i

`vexpv_i` — Performs exponential operations between two vectorial control signals at init time.

## Description

Performs exponential operations between two vectorial control signals at init time.

## Syntax

```
vexpv_i ifn1, ifn2, ielements [, idstoffset] [, isrcoffset]
```

## Initialization

*ifn1* - number of the table hosting the first vector to be processed

*ifn2* - number of the table hosting the second vector to be processed

*ielements* - number of elements of the two vectors

*idstoffset* - index offset for the destination (ifn1) table (Default=0)

*isrcoffset* - index offset for the source (ifn2) table (Default=0)

## Performance

`vexpv_i` elevates each element of ifn2 to the corresponding element of ifn1. Each vectorial signal is hosted by a table (ifn1 and ifn2). The number of elements contained in both vectors must be the same.

The result is a new vectorial control signal that overrides old values of ifn1. If you want to keep the old ifn1 vector, use `vcopy_i` opcode to copy it in another table. You can use *idstoffset* and *isrcoffset* to specify vectors in any location of the tables.

Negative values for *idstoffset* and *isrcoffset* are acceptable. If *idstoffset* is negative, the out of range section of the vector will be discarded. If *isrcoffset* is negative, the out of range elements will be assumed to be 1 (i.e. the destination elements will be set to 1). If elements for the destination vector are beyond the size of the table (including guard point), these elements are discarded (i.e. elements do not wrap around the tables). If elements for the source vector are beyond the table length, these elements are taken as 1 (i.e. the destination vector elements will be set to 1).

### Warning

Using the same table as source and destination table in versions earlier than 5.04, might produce unexpected behavior, so use with care.

This opcode works at init time. There's an k-rate version of this opcode called `vexpv`.

All these operators (`vaddv_i`, `vsubv_i`, `vmultv_i`, `vdivv_i`, `vpowv_i`, `vexpv_i`, `vcopy` and `vmap`) are designed to be used together with other opcodes that operate with vectorial signals such as `vcella`, `adsynt`, `adsynt2` etc.

# vibes

vibes — Physical model related to the striking of a metal block.

## Description

Audio output is a tone related to the striking of a metal block as found in a vibraphone. The method is a physical model developed from Perry Cook, but re-coded for Csound.

## Syntax

```
ares vibes kamp, kfreq, ihrd, ipos, imp, kvibf, kvamp, ivibfn, idec
```

## Initialization

*ihrd* -- the hardness of the stick used in the strike. A range of 0 to 1 is used. 0.5 is a suitable value.

*ipos* -- where the block is hit, in the range 0 to 1.

*imp* -- a table of the strike impulses. The file *marmstk1.wav* [examples/marmstk1.wav] is a suitable function from measurements and can be loaded with a *GEN01* table. It is also available at <ftp://ftp.cs.bath.ac.uk/pub/dream/documentation/sounds/modelling/>.

*ivfn* -- shape of tremolo, usually a sine table, created by a function

*idec* -- time before end of note when damping is introduced

## Performance

*kamp* -- Amplitude of note.

*kfreq* -- Frequency of note played.

*kvibf* -- frequency of tremolo in Hertz. Suggested range is 0 to 12

*kvamp* -- amplitude of the tremolo

## Examples

Here is an example of the vibes opcode. It uses the file *vibes.csd* [examples/vibes.csd], and *marmstk1.wav* [examples/marmstk1.wav].

### Example 1002. Example of the vibes opcode.

# vibr

vibr — Easier-to-use user-controllable vibrato.

## Description

Easier-to-use user-controllable vibrato.

## Syntax

```
kout vibr kAverageAmp, kAverageFreq, ifn
```

## Initialization

*ifn* -- Number of vibrato table. It normally contains a sine or a triangle wave.

## Performance

*kAverageAmp* -- Average amplitude value of vibrato

*kAverageFreq* -- Average frequency value of vibrato (in cps)

*vibr* is an easier-to-use version of *vibrato*. It has the same generation-engine of *vibrato*, but the parameters corresponding to missing input arguments are hard-coded to default values.

## Examples

Here is an example of the vibr opcode. It uses the file *vibr.csd* [examples/vibr.csd].

### Example 1003. Example of the vibr opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# vibrato

**vibrato** — Generates a natural-sounding user-controllable vibrato.

## Description

Generates a natural-sounding user-controllable vibrato.

## Syntax

```
kout vibrato kAverageAmp, kAverageFreq, kRandAmountAmp, kRandAmountFreq, kAmpMinRate, kAmpMaxRate, kcps
```

## Initialization

*ifn* -- Number of vibrato table. It normally contains a sine or a triangle wave.

*iphs* -- (optional) Initial phase of table, expressed as a fraction of a cycle (0 to 1). A negative value will cause phase initialization to be skipped. The default value is 0.

## Performance

*kAverageAmp* -- Average amplitude value of vibrato

*kAverageFreq* -- Average frequency value of vibrato (in cps)

*kRandAmountAmp* -- Amount of random amplitude deviation

*kRandAmountFreq* -- Amount of random frequency deviation

*kAmpMinRate* -- Minimum frequency of random amplitude deviation segments (in cps)

*kAmpMaxRate* -- Maximum frequency of random amplitude deviation segments (in cps)

*kcpsMinRate* -- Minimum frequency of random frequency deviation segments (in cps)

*kcpsMaxRate* -- Maximum frequency of random frequency deviation segments (in cps)

*vibrato* outputs a natural-sounding user-controllable vibrato. The concept is to randomly vary both frequency and amplitude of the oscillator generating the vibrato, in order to simulate the irregularities of a real vibrato.

In order to have a total control of these random variations, several input arguments are present. Random variations are obtained by two separated segmented lines, the first controlling amplitude deviations, the second the frequency deviations. Average duration of each segment of each line can be shortened or enlarged by the arguments *kAmpMinRate*, *kAmpMaxRate*, *kcpsMinRate*, *kcpsMaxRate*, and the deviation from the average amplitude and frequency values can be independently adjusted by means of *kRandAmountAmp* and *kRandAmountFreq*.

## Examples

Here is an example of the vibrato opcode. It uses the file *vibrato.csd* [examples/vibrato.csd].

### Example 1004. Example of the vibrato opcode.

# vincr

**vincr** — Accumulates audio signals.

## Description

*vincr* increments one audio variable with another signal, i.e. it accumulates output.

## Syntax

```
vincr accum, aincr
```

## Performance

*accum* -- audio-rate accumulator variable to be incremented

*aincr* -- incrementing signal

*vincr* (variable increment) and *clear* are intended to be used together. *vincr* stores the result of the sum of two audio variables into the first variable itself (which is intended to be used as an accumulator in polyphony). The accumulator is typically a global variable that is used to combine signals from several sources (different instruments or instrument instances) for further processing (for example, via a global effect that reads the accumulator) or for outputting the combined signal by some means other than one of the *out* opcodes (eg. via the *fout* opcode). After the accumulator is used, the accumulator variable should be set to zero by means of the *clear* opcode (or it will explode).

## Examples

The following example uses the *vincr* opcode. It uses the file *vincr.csd* [examples/vincr.csd].

### Example 1005. Example of the vincr opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# vlimit

vlimit — Limiting and Wrapping Vectorial Signals

## Description

Limits elements of vectorial control signals.

## Syntax

```
vlimit ifn, kmin, kmax, ielements
```

## Initialization

*ifn* - number of the table hosting the vector to be processed

*ielements* - number of elements of the vector

## Performance

*kmin* - minimum threshold value

*kmax* - maximum threshold value

*vlimit* set lower and upper limits on each element of the vector they process.

These opcodes are similar to *limit*, *wrap* and *mirror*, but operate with a vectorial signal instead of with a scalar signal.

Result overrides old values of *ifn1*, if these are out of min/max interval. If you want to keep input vector, use *vcopy* opcode to copy it in another table.

All these opcodes are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2* etc.

## Credits

Written by Gabriel Maldonado.

# vlinseg

vlinseg — Vectorial envelope generator

## Description

Generate linear vectorial segments

## Syntax

```
vlinseg  ifnout, ielements, ifn1, idur1, ifn2 [, idur2, ifn3 [...]]
```

## Initialization

*ifnout* - number of table hosting output vectorial signal

*ifn1* - starting vector

*ifn2,ifn3,etc.* - vector after *idurx* seconds

*idur1* - duration in seconds of first segment.

*idur2, idur3, etc.* - duration in seconds of subsequent segments.

*ielements* - number of elements of vectors.

## Performance

These opcodes are similar to *linseg* and *expseg*, but operate with vectorial signals instead of with scalar signals.

Output is a vectorial control signal hosted by *ifnout* (that must be previously allocated), while each break-point of the envelope is actually a vector of values. All break-points must contain the same number of elements (*ielements*).

All these operators are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2*, etc.

## Example

Here is an example of the vlinseg opcode. It uses the files *vlinseg.csd* [examples/vlinseg.csd].

# vlowres

vlowres — A bank of filters in which the cutoff frequency can be separated under user control.

## Description

A bank of filters in which the cutoff frequency can be separated under user control

## Syntax

```
ares vlowres asig, kfco, kres, iord, ksep
```

## Initialization

*iord* -- total number of filters (1 to 10)

## Performance

*asig* -- input signal

*kfco* -- frequency cutoff (not in Hz)

*kres* -- resonance amount

*ksep* -- frequency cutoff separation for each filter: the first filter has a kfreq cutoff, the second has a kfreq + ksep and the third kf freq + 2\*ksep and so on, depending on the number of filters.

*vlowres* (variable resonant lowpass filter) allows a variable response curve in resonant filters. It can be thought of as a bank of lowpass resonant filters, each with the same resonance, serially connected. The frequency cutoff of each filter can vary with the *kfco* and *ksep* parameters.

## Examples

Here is an example of the vlowres opcode. It uses the file *vlowres.csd* [examples/vlowres.csd].

### Example 1008. Example of the vlowres opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# vmap

vmap — Maps elements from a vector according to indexes contained in another vector.

## Description

Maps elements from a vector onto another according to the indexes of a this vector.

## Syntax

```
vmap ifn1, ifn2, ielements [,idstoffset, isrcoffset]
```

## Initialization

*ifn1* - number of the table where the vectorial signal will be copied, and which contains the mapping vector

*ifn2* - number of the table hosting the vectorial signal to be copied

*ielements* - number of elements to process

*idstoffset* - index offset for destination table (*ifn1*)

*isrcoffset* - index offset for source table (*ifn2*)

## Performance

*vmap* maps elements of *ifn2* according to the values of table *ifn1*. Elements of *ifn1* are treated as indexes of table *ifn2*, so element values of *ifn1* must not exceed the length of *ifn2* table otherwise a Csound will report an error. Elements of *ifn1* are treated as integers, so any fractional part will be truncated. There is no interpolation performed on this operation.

In practice, what happens is that the elements of *ifn1* are used as indexes to *ifn2*, and then are replaced by the corresponding elements from *ifn2*. *ifn1* must be different from *ifn2*, otherwise the results are unpredictable. Csound will produce an init error if they are not.

All these operators (*vaddv*, *vsubv*, *vmultv*, *vdivv*, *vpowv*, *vexpv*, *vcopy* and *vmap*) are designed to be used together with other opcodes that operate with vectorial signals such as, *vcella*, *adsynt*, *adsynt2*, etc.

## Examples

Here is an example of the vmap opcode. It uses the file *vmap.csd* [examples/vmap.csd].

# vmirror

vmirror — Limiting and Wrapping Vectorial Signals

## Description

'Reflects' elements of vectorial control signals on thresholds.

## Syntax

```
vmirror ifn, kmin, kmax, ielements
```

## Initialization

*ifn* - number of the table hosting the vector to be processed

*ielements* - number of elements of the vector

## Performance

*kmin* - minimum threshold value

*kmax* - maximum threshold value

*vmirror* 'reflects' each element of corresponding vector if it exceeds low or high thresholds.

These opcodes are similar to *limit*, *wrap* and *mirror*, but operate with a vectorial signal instead of with a scalar signal.

Result overrides old values of *ifn1*, if these are out of min/max interval. If you want to keep input vector, use *vcopy* opcode to copy it in another table.

All these opcodes are designed to be used together with other opcodes that operate with vectorial signals such as, *vcella*, *adsynt*, *adsynt2* etc.

# vmult

vmult — Multiplies a vector in a table by a scalar value.

## Description

Multiplies a vector in a table by a scalar value.

## Syntax

```
vmult ifn, kval, kelements [, kdstoffset] [, kverbose]
```

## Initialization

*ifn* - number of the table hosting the vectorial signal to be processed

## Performance

*kval* - scalar value to be multiplied

*kelements* - number of elements of the vector

*kdstoffset* - index offset for the destination table (Optional, default = 0)

*kverbose* - Selects whether or not warnings are printed (Default=0)

*vmult* multiplies each element of the vector contained in the table *ifn* by *kval*, starting from table index *kdstoffset*. This enables you to process a specific section of a table by specifying the offset and the number of elements to be processed. Offset is counted starting from 0, so if no offset is specified (or set to 0), the table will be modified from the beginning.

Note that this opcode runs at k-rate so the value of *kval* is multiplied every control period. Use with care or you will end up with very large numbers (or use *vmult\_i*).

These opcodes (*vadd*, *vmult*, *vpow* and *vexp*) perform numeric operations between a vectorial control signal (hosted by the table *ifn*), and a scalar signal (*kval*). Result is a new vector that overrides old values of *ifn*. All these opcodes work at k-rate.

Negative values for *kdstoffset* are valid. Elements from the vector that are outside the table, will be discarded, and they will not wrap around the table.

If the optional *kverbose* argument is different to 0, the opcode will print warning messages every k-pass if table lengths are exceeded.

In all these opcodes, the resulting vectors are stored in *ifn*, overriding the initial vectors. If you want to keep initial vector, use *vcopy* or *vcopy\_i* to copy it in another table. All these operators are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2*, etc. They can also be useful in conjunction with the spectral opcodes *pvsftw* and *pvsftr*.

### Note

Please note that the *elements* argument has changed in version 5.03 from i-rate to k-rate. This will change the opcode's behavior in the unusual cases where the i-rate variable *iele-*

*ments* is changed inside the instrument, for example in:

```
instr 1
ielements = 10
ielements = 20
vadd 1, 1, ielements
vadd 2, 1, ielements
turnoff
endin
```

## Example

Here is an example of the `vmult` opcode. It uses the file `vmult-2.cs` [examples/vmult-2.cs].

# vmult\_i

vmult\_i — Multiplies a vector in a table by a scalar value.

## Description

Multiplies a vector in a table by a scalar value.

## Syntax

```
vmult_i ifn, ival, ielements [, idstoffset]
```

## Initialization

*ifn* - number of the table hosting the vectorial signal to be processed

*ival* - scalar value to be multiplied

*ielements* - number of elements of the vector

*idstoffset* - index offset for the destination table

## Performance

*vmult\_i* multiplies each element of the vector contained in the table *ifn* by *ival*, starting from table index *idstoffset*. This enables you to process a specific section of a table by specifying the offset and the number of elements to be processed. Offset is counted starting from 0, so if no offset is specified (or set to 0), the table will be modified from the beginning.

This opcode runs only on initialization, there is a k-rate version of this opcode called *vmult*.

Negative values for *idstoffset* are valid. Elements from the vector that are outside the table, will be discarded, and they will not wrap around the table.

In all these opcodes, the resulting vectors are stored in *ifn*, overriding the initial vectors. If you want to keep initial vector, use *vcopy* or *vcopy\_i* to copy it in another table. All these operators are designed to be used together with other opcodes that operate with vectorial signals such as, *vcella*, *adsynt*, *adsynt2*, etc. They can also be useful in conjunction with the spectral opcodes *pvsftw* and *pvsftr*.

## Examples

Here is an example of the *vmult\_i* opcode. It uses the file *vmult\_i.csd* [examples/vmult\_i.csd].

### Example 1012. Example of the **vmult\_i** opcode.

# vmultv

vmultv — Performs multiplication between two vectorial control signals

## Description

Performs multiplication between two vectorial control signals

## Syntax

```
vmultv ifn1, ifn2, kelements [, kdstoffset] [, ksrcoffset] [,kverbose]
```

## Initialization

*ifn1* - number of the table hosting the first vector to be processed

*ifn2* - number of the table hosting the second vector to be processed

## Performance

*kelements* - number of elements of the two vectors

*kdstoffset* - index offset for the destination (*ifn1*) table (Default=0)

*ksrcoffset* - index offset for the source (*ifn2*) table (Default=0)

*kverbose* - Selects whether or not warnings are printed (Default=0)

*vmultv* multiplies two vectorial control signals, that is, each element of the first vector is processed (only) with the corresponding element of the other vector. Each vectorial signal is hosted by a table (*ifn1* and *ifn2*). The number of elements contained in both vectors must be the same.

The Result is a new vectorial control signal that overrides old values of *ifn1*. If you want to keep the old *ifn1* vector, use *vcopy\_i* opcode to copy it in another table. You can use *kdstoffset* and *ksrcoffset* to specify vectors in any location of the tables.

Negative values for *kdstoffset* and *ksrcoffset* are acceptable. If *kdstoffset* is negative, the out of range section of the vector will be discarded. If *ksrcoffset* is negative, the out of range elements will be assumed to be 1 (i.e. the destination elements will not be changed). If elements for the destination vector are beyond the size of the table (including guard point), these elements are discarded (i.e. elements do not wrap around the tables). If elements for the source vector are beyond the table length, these elements are taken as 1 (i.e. the destination vector will not be changed for these elements).

If the optional *kverbose* argument is different to 0, the opcode will print warning messages every k-pass if table lengths are exceeded.

## Warning

Using the same table as source and destination table in versions earlier than 5.04, might produce unexpected behavior, so use with care.

This opcode works at k-rate (this means that every k-pass the vectors are multiplied). There's an i-rate

version of this opcode called *vmultv\_i*.

## Note

Please note that the *elements* argument has changed in version 5.03 from i-rate to k-rate. This will change the opcode's behavior in the unusual cases where the i-rate variable *ielements* is changed inside the instrument, for example in:

```
instr 1
ielements =      10
                vadd    1, 1, ielements
ielements =      20
                vadd    2, 1, ielements
                turnoff
endin
```

All these operators (*vaddv*, *vsubv*, *vmultv*, *vdivv*, *vpowv*, *vexpv*, *vcopy* and *vmap*) are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2* etc.

## Examples

Here is an example of the *vmultv* opcode. It uses the file *vmultv.csd* [examples/vmultv.csd].

### Example 1013. Example of the *vmultv* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## **vmultv\_i**

**vmultv\_i** — Performs multiplication between two vectorial control signals at init time.

## **Description**

Performs multiplication between two vectorial control signals at init time.

## **Syntax**

```
vmultv_i ifn1, ifn2, ielements [, idstoffset] [, isrcoffset]
```

## **Initialization**

*ifn1* - number of the table hosting the first vector to be processed

*ifn2* - number of the table hosting the second vector to be processed

*ielements* - number of elements of the two vectors

*idstoffset* - index offset for the destination (ifn1) table (Default=0)

*isrcoffset* - index offset for the source (ifn2) table (Default=0)

## **Performance**

*vmultv\_i* multiplies two vectorial control signals, that is, each element of the first vector is processed (only) with the corresponding element of the other vector. Each vectorial signal is hosted by a table (ifn1 and ifn2). The number of elements contained in both vectors must be the same.

The result is a new vectorial control signal that overrides old values of ifn1. If you want to keep the old ifn1 vector, use *vcopy\_i* opcode to copy it in another table. You can use *idstoffset* and *isrcoffset* to specify vectors in any location of the tables.

Negative values for *idstoffset* and *isrcoffset* are acceptable. If *idstoffset* is negative, the out of range section of the vector will be discarded. If *isrcoffset* is negative, the out of range elements will be assumed to be 1 (i.e. the destination elements will not be changed). If elements for the destination vector are beyond the size of the table (including guard point), these elements are discarded (i.e. elements do not wrap around the tables). If elements for the source vector are beyond the table length, these elements are taken as 1 (i.e. the destination vector will not be changed for these elements).

### **Warning**

Using the same table as source and destination table in versions earlier than 5.04, might produce unexpected behavior, so use with care.

This opcode works at init time. There's an k-rate version of this opcode called *vmultv*.

All these operators (*vaddv\_i*, *vsubv\_i*, *vmultv\_i*, *vdivv\_i*, *vpowv\_i*, *vexpv\_i*, *vcopy* and *vmap*) are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2* etc.

# voice

voice — An emulation of a human voice.

## Description

An emulation of a human voice.

## Syntax

```
ares voice kamp, kfreq, kphoneme, kform, kvibf, kvamp, ifn, ivfn
```

## Initialization

*ifn, ivfn* -- two table numbers containing the carrier waveform and the vibrato waveform. The files *impuls20.aiff* [examples/impuls20.aiff], *ahh.aiff* [examples/ahh.aiff], *eee.aiff* [examples/eee.aiff], or *ooo.aiff* [examples/ooo.aiff] are suitable for the first of these, and a sine wave for the second. These files are available from <ftp://ftp.cs.bath.ac.uk/pub/dream/documentation/sounds/modelling/>.

## Performance

*kamp* -- Amplitude of note.

*kfreq* -- Frequency of note played. It can be varied in performance.

*kphoneme* -- an integer in the range 0 to 16, which select the formants for the sounds:

- “eee”, “ihh”, “ehh”, “aaa”,
- “ahh”, “aww”, “ohh”, “uhh”,
- “uuu”, “ooo”, “rrr”, “lll”,
- “mmm”, “nnn”, “nng”, “ngg”.

At present the phonemes

- “fff”, “sss”, “thh”, “shh”,
- “xxx”, “hee”, “hoo”, “hah”,
- “bbb”, “ddd”, “jjj”, “ggg”,
- “vvv”, “zzz”, “thz”, “zh”

are not available (!)

*kform* -- Gain on the phoneme. values 0.0 to 1.2 recommended.

*kvibf* -- frequency of vibrato in Hertz. Suggested range is 0 to 12

*kvamp* -- amplitude of the vibrato

## Examples

Here is an example of the voice opcode. It uses the file *voice.csd* [examples/voice.csd], and *impuls20.aiff* [examples/impuls20.aiff].

### Example 1014. Example of the voice opcode.

# vosim

vosim — Simple vocal simulation based on glottal pulses with formant characteristics.

## Description

This opcode produces a simple vocal simulation based on glottal pulses with formant characteristics. Output is a series of sound events, where each event is composed of a burst of squared sine pulses followed by silence. The VOSIM (VOcal SIMulation) synthesis method was developed by Kaegi and Tempelaars in the 1970's.

## Syntax

```
ar vosim kamp, kFund, kForm, kDecay, kPulseCount, kPulseFactor, ifn [, iskip]
```

## Initialization

*ifn* - a sound table, normally containing half a period of a sinewave, squared (see notes below).

*iskip* - (optional) Skip initialization, for tied notes.

## Performance

*ar* - output signal. Note that the output is usually unipolar - positive only.

*kamp* - output amplitude, the peak amplitude of the first pulse in each burst.

*kFund* - fundamental pitch, in Herz. Each event is 1/*kFund* seconds long.

*kForm* - formant center frequency. Length of each pulse in the burst is 1/*kForm* seconds.

*kDecay* - a dampening factor from pulse to pulse. This is subtracted from amplitude on each new pulse.

*kPulseCount* - number of pulses in the burst part of each event.

*kPulseFactor* - the pulse width is multiplied by this value at each new pulse. This results in formant sweeping. If factor is < 1.0, the formant sweeps up, if > 1.0 each new pulse is longer, so the formant sweeps down. The final pitch of the formant is *kForm* \* pow(*kPulseFactor*, *kPulseCount*)

The output of *vosim* is a series of sound events, where each event is composed of a burst of squared sine pulses followed by silence. The total duration of the events determines fundamental frequency. The length of each single pulse in the squared-sine bursts produce a formant frequency band. The width of the formant is determined by rate of silence to pulses (see below). The final result is also shaped by the dampening factor from pulse to pulse.

A small practical problem in using this opcode is that no GEN function will create a squared sine wave out of the box. Something like the following can be used to create the appropriate table from the score.

```
; use GEN09 to create half a sine in table 17
f 17 time size 9 0.5 1 0
; run instr 101 on table 17 for a single init-pass
i 101 0 0 17
```

It can also be done with an instrument writing to an f-table in the orchestra:

```
; square each point in table #p4. This should be run as init-only, just once in the performance
instr 101
    index tablelen p4
    index = index - 1 ; start from last point
loop:
    ival table index, p4
    ival = ival * ival
    tableiw ival, index, p4
    index = index - 1
    if index < 0 igoto endloop
        igoto loop
endloop:
endin
```

## Parameter Limits

The count of pulses multiplied by pulse width should fit in the event length ( $1/kFund$ ). If this is not fulfilled, the algorithm does not break, we just do not start any pulses that would outlast the event. This might introduce a silence at end of event even if none was intended. In consequence,  $kForm$  should be higher than  $kFund$ , otherwise only silence is output.

*Vosim* was created to emulate voice sounds using a model of glottal pulse. Rich sounds can be created by combining several instances of *vosim* with different parameters. One drawback is that the signal is not band-limited. But as the authors point out, attenuation of high-pitch components is -60 dB at 6 times the fundamental frequency. The signal can also be changed by changing the source signal in the lookup table. The technique has historical interest, and can produce rich sound very cheaply (each sample requires only a table lookup and a single multiplication for attenuation).

As stated, formant bandwidth depends on the ratio between pulse burst and silence in an event. But this is not an independent parameter: The fundamental decides event length, and formant center defines the pulse length. It is therefore impossible to guarantee a specific burst/silence ratio, since the burst length has to be an integer multiple of pulse length. The decay of pulses can be used to smooth the transition from N to N+/-1 pulses, but there will still be steps in the spectral profile of output. The example code below shows one approach to this.

All input parameters are k-rate. The input parameters are only used to set up each new event (or grain). Event amplitude is fixed for each event at initialization. In normal parameter ranges, when  $ksmps < 500$ , the k-rate parameters are updated more often than events are created. In any case, no wide-band noise will be injected in the system due to k-rate inputs being updated less often than they are read, but some other artefacts could be created.

The opcode should behave reasonably in the face of all user inputs. Some details:

- a.  $kFund < 0$ : This is forced to positive - no point in "reversed" events.
- b.  $kFund == 0$ : This leads to "infinite" length event, ie a pulse burst followed by very long indefinite silence.
- c.  $kForm == 0$ : This leads to infinite length pulse, so no pulses are generated (i.e. silence).
- d.  $kForm < 0$ : Table is read backward. If table is symmetric,  $kform$  and  $-kform$  should give bit-identical outputs.

- e. kPulseFactor == 0: Second pulse onwards is zero. See (c).
- f. kPulseFactor < 0: Pulses alternately read table forward and reversed.

With asymmetric pulse table there may be some use for negative *kForm* or negative *kPulseFactor*.

## Examples

Here is an example of the vosim opcode. It uses the file *vosim.csd* [examples/vosim.csd].

### Example 1015. Example of the vosim opcode.

# vphaseseg

`vphaseseg` — Allows one-dimensional HVS (Hyper-Vectorial Synthesis).

## Description

`vphaseseg` allows one-dimensional HVS (Hyper-Vectorial Synthesis).

## Syntax

```
vphaseseg kphase, ioutab, ielems, itab1,idist1,itab2 \
[,idist2,itab3, ... ,idistN-1,itabN]
```

## Initialization

*ioutab* - number of output table.

*ielem* - number of elements to process

*itab1,...,itabN* - breakpoint table numbers

*idist1,...,idistN-1* - distances between breakpoints in percentage values

## Performance

*kphase* - phase pointer

`vphaseseg` returns the coordinates of section points of an N-dimensional space path. The coordinates of section points are stored into an output table. The number of dimensions of the N-dimensional space is determined by the *ielem* argument that is equal to N and can be set to any number. To define the path, user have to provide a set of points of the N-dimensional space, called break-points. Coordinates of each break-point must be contained by a different table. The number of coordinates to insert in each break-point table must obviously equal to *ielem* argument. There can be any number of break-point tables filled by the user.

Hyper-Vectorial Synthesis actually deals with two kinds of spaces. The first space is the N-dimensional space in which the path is defined, this space is called time-variant parameter space (or SPACE A). The path belonging to this space is covered by moving a point into the second space that normally has a number of dimensions smaller than the first. Actually, the point in motion is the projection of corresponding point of the N-dimensional space (could also be considered a section of the path). The second space is called user-pointer-motion space (or SPACE B) and, in the case of `vphaseseg` opcode, has only ONE DIMENSION. Space B is covered by means of *kphase* argument (that is a sort of path pointer), and its range is 0 to 1. The output corresponding to current pointer value is stored in *ioutab* table, whose data can be afterwards used to control any synthesis parameters.

In `vphaseseg`, each break-point is separated from the other by a distance expressed in percentage, where all the path length is equal to the sum of all distances. So distances between breakpoints can be different, differently from kinds of HVS in which space B has more than one dimension, in these cases distance between break-points MUST be THE SAME for all intervals.

# vport

vport — Vectorial Control-rate Delay Paths

## Description

Generate a sort of 'vectorial' portamento

## Syntax

```
vport ifn, khtime, ielements [, ifnInit]
```

## Initialization

*ifn* - number of the table containing the output vector

*ielements* - number of elements of the two vectors

*ifnInit* (optional) - number of the table containing a vector whose elements contain initial portamento values.

## Performance

*vport* is similar to *port*, but operates with vectorial signals, instead of with scalar signals. Each vector element is treated as an independent control signal. Input and output vectors are placed in the same table and output vector overrides input vector. If you want to keep input vector, use *vcopy* opcode to copy it in another table.

## Credits

Written by Gabriel Maldonado.

New in Csound 5 (Previously available only on CsoundAV)

# vpow

vpow — Raises each element of a vector to a scalar power.

## Description

Raises each element of a vector to a scalar power.

## Syntax

```
vpow ifn, kval, kelements [, kdstoffset] [, kverbose]
```

## Initialization

*ifn* - number of the table hosting the vectorial signal to be processed

## Performance

*kval* - scalar value to which the elements of *ifn* will be raised

*kelements* - number of elements of the vector

*kdstoffset* - index offset for the destination table (Optional, default = 0)

*kverbose* - Selects whether or not warnings are printed (Default=0)

*vpow* raises each element of the vector contained in the table *ifn* to the power of *kval*, starting from table index *kdstoffset*. This enables you to process a specific section of a table by specifying the offset and the number of elements to be processed. Offset is counted starting from 0, so if no offset is specified (or set to 0), the table will be modified from the beginning.

Note that this opcode runs at k-rate so the value of *kval* is processed every control period. Use with care or you will end up with very large (or small) numbers (or use *vpow\_i*).

These opcodes (*vadd*, *vmult*, *vpow* and *vexp*) perform numeric operations between a vectorial control signal (hosted by the table *ifn*), and a scalar signal (*kval*). Result is a new vector that overrides old values of *ifn*. All these opcodes work at k-rate.

Negative values for *kdstoffset* are valid. Elements from the vector that are outside the table, will be discarded, and they will not wrap around the table.

If the optional *kverbose* argument is different to 0, the opcode will print warning messages every k-pass if table lengths are exceeded.

In all these opcodes, the resulting vectors are stored in *ifn*, overriding the initial vectors. If you want to keep initial vector, use *vcopy* or *vcopy\_i* to copy it in another table. All these operators are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2*, etc. They can also be useful in conjunction with the spectral opcodes *pvsftw* and *pvsftr*.

### Note

Please note that the *elements* argument has changed in version 5.03 from i-rate to k-rate. This will change the opcode's behavior in the unusual cases where the i-rate variable *iele-*

ments is changed inside the instrument, for example in:

```
instr 1
ielements = 10
ielements = 20
vadd 1, 1, ielements
vadd 2, 1, ielements
turnoff
endin
```

## Examples

Here is an example of the vpow opcode. It uses the file *vpow.csd* [examples/vpow.csd].

# vpow\_i

vpow\_i — Raises each element of a vector to a scalar power

## Description

Raises each element of a vector to a scalar power

## Syntax

```
vpow_i ifn, ival, ielements [, idstoffset]
```

## Initialization

*ifn* - number of the table hosting the vectorial signal to be processed

*ielements* - number of elements of the vector

*ival* - scalar value to which the elements of *ifn* will be raised

*idstoffset* - index offset for the destination table

## Performance

*vpow\_i* elevates each element of the vector contained in the table *ifn* to the power of *ival*, starting from table index *idstoffset*. This enables you to process a specific section of a table by specifying the offset and the number of elements to be processed. Offset is counted starting from 0, so if no offset is specified (or set to 0), the table will be modified from the beginning.

This opcode runs only on initialization, there is a k-rate version of this opcode called *vpow*.

Negative values for *idstoffset* are valid. Elements from the vector that are outside the table, will be discarded, and they will not wrap around the table.

In all these opcodes, the resulting vectors are stored in *ifn*, overriding the initial vectors. If you want to keep initial vector, use *vcopy* or *vcopy\_i* to copy it in another table. All these operators are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2*, etc. They can also be useful in conjunction with the spectral opcodes *pvsftw* and *pvsftr*.

## Examples

Here is an example of the vpow\_i opcode. It uses the file *vpow\_i.csd* [examples/vpow\_i.csd].

### Example 1018. Examples of the vpow\_i opcode.

# vpowv

vpowv — Performs power-of operations between two vectorial control signals

## Description

Performs power-of operations between two vectorial control signals

## Syntax

```
vpowv ifn1, ifn2, kelements [, kdstoffset] [, ksrcoffset] [,kverbose]
```

## Initialization

*ifn1* - number of the table hosting the first vector to be processed

*ifn2* - number of the table hosting the second vector to be processed

## Performance

*kelements* - number of elements of the two vectors

*kdstoffset* - index offset for the destination (*ifn1*) table (Default=0)

*ksrcoffset* - index offset for the source (*ifn2*) table (Default=0)

*kverbose* - Selects whether or not warnings are printed (Default=0)

*vpowv* raises each element of *ifn1* to the corresponding element of *ifn2*. Each vectorial signal is hosted by a table (*ifn1* and *ifn2*). The number of elements contained in both vectors must be the same.

The result is a new vectorial control signal that overrides old values of *ifn1*. If you want to keep the old *ifn1* vector, use *vcopy\_i* opcode to copy it in another table. You can use *kdstoffset* and *ksrcoffset* to specify vectors in any location of the tables.

Negative values for *kdstoffset* and *ksrcoffset* are acceptable. If *kdstoffset* is negative, the out of range section of the vector will be discarded. If *ksrcoffset* is negative, the out of range elements will be assumed to be 1 (i.e. the destination elements will not be changed). If elements for the destination vector are beyond the size of the table (including guard point), these elements are discarded (i.e. elements do not wrap around the tables). If elements for the source vector are beyond the table length, these elements are taken as 1 (i.e. the destination vector will not be changed for these elements).

If the optional *kverbose* argument is different to 0, the opcode will print warning messages every k-pass if table lengths are exceeded.

### Warning

Using the same table as source and destination table in versions earlier than 5.04, might produce unexpected behavior, so use with care.

This opcode works at k-rate (this means that every k-pass the vectors are processed). There's an i-rate version of this opcode called *vpowv\_i*.

## Note

Please note that the *elements* argument has changed in version 5.03 from i-rate to k-rate. This will change the opcode's behavior in the unusual cases where the i-rate variable *ielements* is changed inside the instrument, for example in:

```
instr 1
ielements = 10
vadd 1, 1, ielements
ielements = 20
vadd 2, 1, ielements
turnoff
endin
```

All these operators (*vaddy*, *vsubv*, *vmultv*, *vdivv*, *vpowv*, *vexpv*, *vcopy* and *vmap*) are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2*, etc.

## Examples

Here is an example of the *vpowv* opcode. It uses the file *vpowv.csd* [examples/vpowv.csd].

### Example 1020. Example of the *vpowv* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## vpowv\_i

vpowv\_i — Performs power-of operations between two vectorial control signals at init time.

## Description

Performs power-of operations between two vectorial control signals at init time.

## Syntax

```
vpowv_i ifn1, ifn2, ielements [, idstoffset] [, isrcoffset]
```

## Initialization

*ifn1* - number of the table hosting the first vector to be processed

*ifn2* - number of the table hosting the second vector to be processed

*ielements* - number of elements of the two vectors

*idstoffset* - index offset for the destination (ifn1) table

*isrcoffset* - index offset for the source (ifn2) table

## Performance

*vpowv\_i* raises each element of ifn1 to the corresponding element of ifn2. Each vectorial signal is hosted by a table (ifn1 and ifn2). The number of elements contained in both vectors must be the same.

The result is a new vectorial control signal that overrides old values of ifn1. If you want to keep the old ifn1 vector, use *vcopy\_i* opcode to copy it in another table. You can use *idstoffset* and *isrcoffset* to specify vectors in any location of the tables.

Negative values for *idstoffset* and *isrcoffset* are acceptable. If *idstoffset* is negative, the out of range section of the vector will be discarded. If *isrcoffset* is negative, the out of range elements will be assumed to be 1 (i.e. the destination elements will not be changed). If elements for the destination vector are beyond the size of the table (including guard point), these elements are discarded (i.e. elements do not wrap around the tables). If elements for the source vector are beyond the table length, these elements are taken as 1 (i.e. the destination vector will not be changed for these elements).

### Warning

Using the same table as source and destination table in versions earlier than 5.04, might produce unexpected behavior, so use with care.

This opcode works at init time. There's an k-rate version of this opcode called *vpowv*.

All these operators (*vaddv\_i*, *vsubv\_i*, *vmultv\_i*, *vdivv\_i*, *vpowv\_i*, *vexpv\_i*, *vcopy* and *vmap*) are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2* etc.

# vpvoc

`vpvoc` — Implements signal reconstruction using an fft-based phase vocoder and an extra envelope.

## Description

Implements signal reconstruction using an fft-based phase vocoder and an extra envelope.

## Syntax

```
ares vpvoc ktmpnt, kfmod, ifile [, ispecwp] [, ifn]
```

## Initialization

*ifile* -- the pvoc number (n in *pvoc.n*) or the name in quotes of the analysis file made using *pvanal*. (See *pvoc*.)

*ispecwp* (optional, default=0) -- if non-zero, attempts to preserve the spectral envelope while its frequency content is varied by *kfmod*. The default value is zero.

*ifn* (optional, default=0) -- optional function table containing control information for *vpvoc*. If *ifn* = 0, control is derived internally from a previous *tableseg* or *tablexseg* unit. Default is 0. (New in Csound version 3.59)

## Performance

*ktmpnt* -- The passage of time, in seconds, through the analysis file. *ktmpnt* must always be positive, but can move forwards or backwards in time, be stationary or discontinuous, as a pointer into the analysis file.

*kfmod* -- a control-rate transposition factor: a value of 1 incurs no transposition, 1.5 transposes up a perfect fifth, and .5 down an octave.

This implementation of *pvoc* was originally written by Dan Ellis. It is based in part on the system of Mark Dolson, but the pre-analysis concept is new. The spectral extraction and amplitude gating (new in Csound version 3.56) were added by Richard Karpen based on functions in SoundHack by Tom Erbe.

*vpvoc* is identical to *pvoc* except that it takes the result of a previous *tableseg* or *tablexseg* and uses the resulting function table (passed internally to the *vpvoc*), as an envelope over the magnitudes of the analysis data channels. Optionally, a table specified by *ifn* may be used.

The result is spectral enveloping. The function size used in the *tableseg* should be *framesize*/2, where *framesize* is the number of bins in the phase vocoder analysis file that is being used by the *vpvoc*. Each location in the table will be used to scale a single analysis bin. By using different functions for *ifn1*, *ifn2*, etc.. in the *tableseg*, the spectral envelope becomes a dynamically changing one. See also *tableseg* and *tablexseg*.

## Examples

The following example, using *vpvoc*, shows the use of functions such as

```
f 1 0 256 5 .001 128 1 128 .001
f 2 0 256 5 1 128 .001 128 1
f 3 0 256 7 1 256 1
```

to scale the amplitudes of the separate analysis bins.

```
ktme    line      0, p3, 3 ; time pointer, in seconds, into file
       tablexseg 1, p3*0.5, 2, p3*0.5, 3
apv     vpvc      ktime, 1, "pvoc.file"
```

The result would be a time-varying “spectral envelope” applied to the phase vocoder analysis data. Since this amplifies or attenuates the amount of signal at the frequencies that are paired with the amplitudes which are scaled by these functions, it has the effect of applying very accurate filters to the signal. In this example the first table would have the effect of a band-pass filter, gradually be band-rejected over half the note's duration, and then go towards no modification of the magnitudes over the second half.

Here is a complete example of the vpvc opcode. It uses the file *vpvc.cs* [examples/vpvc.cs].

# vrandh

**vrandh** — Generates a vector of random numbers stored into a table, holding the values for a period of time.

## Description

Generates a vector of random numbers stored into a table, holding the values for a period of time. Generates a sort of 'vectorial band-limited noise'.

## Syntax

```
vrandh ifn, krang, kcps, ielements [, idstoffset] [, iseed] \
[, isize] [, ioffset]
```

## Initialization

*ifn* - number of the table where the vectorial signal will be generated

*ielements* - number of elements of the vector

*idstoffset* - (optional, default=0) -- index offset for the destination table

*iseed* (optional, default=0.5) -- seed value for the recursive pseudo-random formula. A value between 0 and +1 will produce an initial output of  $kamp * iseed$ . A negative value will cause seed re-initialization to be skipped. A value greater than 1 will seed from system time, this is the best option to generate a different random sequence for each run.

*isize* (optional, default=0) -- if zero, a 16 bit number is generated. If non-zero, a 31-bit random number is generated. Default is 0.

*ioffset* - (optional, default=0) -- a base value added to the random result.

## Performance

*krange* - range of random elements (from *-krange* to *krange*).

*kcps* - rate of generated elements in cycles per seconds.

This opcode is similar to *randh*, but operates on vectors instead of with scalar values.

Though the argument *isize* defaults to 0, thus using a 16-bit random number generator, using the newer 31-bit algorithm is recommended, as this will produce a random sequence with a longer period (more random numbers before the sequence starts repeating).

The output is a vector contained in *ifn* (that must be previously allocated).

All these operators are designed to be used together with other opcodes that operate with vector such as *adsynt*, etc.

## Examples

Here is an example of the vrandh opcode. It uses the file *vrandh.csd* [examples/vrandh.csd].

**Example 1022. Example of the vrandh opcode.**

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# vstaudio, vstaudiog

vstaudio — VST audio output.

## Syntax

```
aout1,aout2 vstaudio instance, [ain1, ain2]
```

```
aout1,aout2 vstaudiog instance, [ain1, ain2]
```

## Description

*vstaudio* and *vstaudiog* are used for sending and receiving audio from a VST plugin.

*vstaudio* is used within an instrument definition that contains a *vstmidiout* or *vstnote* opcode. It outputs audio for only that one instrument. Any audio remaining in the plugin after the end of the note, for example a reverb tail, will be cut off and should be dealt with using a damping envelope.

*vstaudiog* (*vstaudio* global) is used in a separate instrument to process audio from any number of VST notes or MIDI events that share the same VST plugin instance (instance). The *vstaudiog* instrument must be numbered higher than all the instruments receiving notes or MIDI data, and the note controlling the *vstplug* instrument must have an indefinite duration, or at least a duration as long as the VST plugin is active.

## Initialization

*instance* - the number which identifies the plugin, to be passed to other *vst4cs* opcodes.

## Performance

*aout1, aout2* - the audio output received from the plugin.

*ain1, ain2* - the audio input sent to the plugin.

## Examples

Here is an example of the use of the *vstaudio* opcode. It uses the file *vst4cs.csd* [examples/vst4cs.csd].

### Example 1024. Example of the *vstaudio* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# vstbankload

vstbankload — Loads parameter banks to a VST plugin.

## Syntax

```
vstbankload instance, ipath
```

## Description

*vstbankload* is used for loading parameter banks to a VST plugin.

## Initialization

*instance* - the number which identifies the plugin, to be passed to other vst4cs opcodes.

*ipath* - the full pathname of the parameter bank (.fxb file).

## Examples

### Example 1025. Example for vstbankload

```
/* orc */
sr      = 44100
kr      = 4410
ksmps  = 10
nchnls = 2

gihandle1 vstinit "c:/vstplugins/cheeze/cheeze machine.dll", 1
instr 4
  vstbankload gihandle1, "c:/vstplugins/cheeze/chengo'scheese.fxb"
  vstinfo    gihandle1
endin

# vstedit

vstedit — Opens the GUI editor window for a VST plugin.

## Syntax

```
vstedit instance
```

## Description

*vstedit* opens the custom GUI editor window for a VST plugin. Note that not all VST plugins have custom GUI editors. It may be necessary to use the *--displays* command-line option to ensure that Csound handles events from the editor window and displays it properly.

## Initialization

*instance* - the number which identifies the plugin, to be passed to other *vst4cs* opcodes.

## Examples

Here is an example of the use of the *vstedit* opcode. It uses the file *vst4cs.csd* [examples/vst4cs.csd].

### Example 1026. Example of the *vstedit* opcode

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# vstinit

`vstinit` — Load a VST plugin into memory for use with the other `vst4cs` opcodes.

## Syntax

```
instance vstinit ilibrarypath [,iverbose]
```

## Description

`vstinit` is used to load a VST plugin into memory for use with the other `vst4cs` opcodes. Both VST effects and instruments (synthesizers) can be used.

## Initialization

*instance* - the number which identifies the plugin, to be passed to other `vst4cs` opcodes.

*ilibrarypath* - the full path to the vst plugin shared library (DLL, on Windows). Remember to use '/' instead of '\' as separator.

*iverbose* - show plugin information and parameters when loading.

## Examples

Here is an example of the use of the `vstinit` opcode. It uses the file `vst4cs.csd` [examples/vst4cs.csd].

### Example 1027. Example of the `vstinit` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# vstinfo

`vstinfo` — Displays the parameters and the programs of a VST plugin.

## Syntax

```
vstinfo instance
```

## Description

`vstinfo` displays the parameters and the programs of a VST plugin.

Note: The *verbose* flag in `vstinit` gives the same information as `vstinfo`. `vstinfo` is useful after loading parameter banks, or when the plugin changes parameters dynamically.

## Initialization

*instance* - the number which identifies the plugin, to be passed to other vst4cs opcodes.

## Examples

Here is an example of the use of the `vstinfo` opcode. It uses the file `vst4cs.csd` [examples/vst4cs.csd].

### Example 1028. Example of the `vstinfo` opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# vstmidiout

vstmidiout — Sends MIDI information to a VST plugin.

## Syntax

```
vstmidiout instance, kstatus, kchan, kdata1, kdata2
```

## Description

*vstmidiout* is used for sending MIDI information to a VST plugin.

## Initialization

*instance* - the number which identifies the plugin, to be passed to other vst4cs opcodes.

## Performance

*kstatus* - the type of midi message to be sent. Currently noteon (144), note off (128), Control Change (176), Program change (192), Aftertouch (208) and Pitch Bend (224) are supported.

*kchan* - the MIDI channel transmitted on.

*kdata1*, *kdata2* - the MIDI data pair, which varies depending on *kstatus*. e.g. note/velocity for note on and note off, Controller number/value for control change.

## Examples

### Example 1029. Example for vstmidiout

```
/* orc */
sr      = 44100
kr      = 4410
ksmps   = 10
nchnls = 2

gihandle1 vstinit "c:/vstplugins/cheeze/cheeze machine.dll", 1

instr 3

## vstnote

`vstnote` — Sends a MIDI note with definite duration to a VST plugin.

## Syntax

```
vstnote instance, kchan, knote, kveloc, kdur
```

## Description

`vstnote` sends a MIDI note with definite duration to a VST plugin.

## Initialization

*instance* - the number which identifies the plugin generated by `vstinit`.

## Performance

*kchan* - The MIDI channel to transmit the note on. Note that MIDI channels are numbered starting from 0.

*knote* - The MIDI note number to send.

*kveloc* - The MIDI note's velocity.

*kdur* - The MIDI note's duration in seconds.

Note: Be sure the instrument containing `vstnote` is not finished before the duration of the note, otherwise you'll have a 'hung' note.

## Examples

Here is an example of the use of the `vstnote` opcode. It uses the file `vst4cs.csd` [examples/vst4cs.csd].

### Example 1030. Example of the `vstnote` opcode

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# vstparamset,vstparamget

*vstparamset* — Used for parameter communication to and from a VST plugin.

## Syntax

```
vstparamset instance, kparam, kvalue  
  
kvalue vstparamget instance, kparam
```

## Description

*vstparamset* and *vstparamget* are used for parameter communication to and from a VST plugin.

## Initialization

*instance* - the number which identifies the plugin, to be passed to other vst4cs opcodes.

## Performance

*kparam* - The number of the parameter to set or get.

*kvalue* - the value to set, or the the value returned by the plugin.

Parameters vary according to the plugin. To find out what parameters are available, use the verbose option when loading the plugin with *vstinit*. Note that the VST protocol specifies that all parameter values must lie between 0.0 and 1.0, inclusive.

## Examples

Here is an example of the use of the *vstparamset* opcode. It uses the file *vst4cs.csd* [examples/vst4cs.csd].

### Example 1031. Example of the *vstparamset* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# vstprogset

vstprogset — Loads parameter banks to a VST plugin.

## Syntax

```
vstprogset instance, kprogram
```

## Description

*vstprogset* sets one of the programs in an .fxb bank.

## Initialization

*instance* - the number which identifies the plugin, to be passed to other vst4cs opcodes.

*kprogram* - the number of the program to set.

## Examples

### Example 1032. Usage of vstprogset

```
/* orc */
sr      = 44100
kr      = 4410
ksmps   = 10
nchnls = 2

# vsurv

vsurv — Performs subtraction between two vectorial control signals

## Description

Performs subtraction between two vectorial control signals

## Syntax

```
vsurv ifn1, ifn2, kelements [, kdstoffset] [, ksrcoffset] [,kverbose]
```

## Initialization

*ifn1* - number of the table hosting the first vector to be processed

*ifn2* - number of the table hosting the second vector to be processed

## Performance

*kelements* - number of elements of the two vectors

*kdstoffset* - index offset for the destination (*ifn1*) table (Default=0)

*ksrcoffset* - index offset for the source (*ifn2*) table (Default=0)

*kverbose* - Selects whether or not warnings are printed (Default=0)

*vsurv* subtracts two vectorial control signals, that is, each element of *ifn2* is subtracted from the corresponding element of *ifn1*. Each vectorial signal is hosted by a table (*ifn1* and *ifn2*). The number of elements contained in both vectors must be the same.

The result is a new vectorial control signal that overrides old values of *ifn1*. If you want to keep the old *ifn1* vector, use *vcopy\_i* opcode to copy it in another table. You can use *kdstoffset* and *ksrcoffset* to specify vectors in any location of the tables.

Negative values for *kdstoffset* and *ksrcoffset* are acceptable. If *kdstoffset* is negative, the out of range section of the vector will be discarded. If *ksrcoffset* is negative, the out of range elements will be assumed to be 0 (i.e. the destination elements will not be changed). If elements for the destination vector are beyond the size of the table (including guard point), these elements are discarded (i.e. elements do not wrap around the tables). If elements for the source vector are beyond the table length, these elements are taken as 0 (i.e. the destination vector will not be changed for these elements).

If the optional *kverbose* argument is different to 0, the opcode will print warning messages every k-pass if table lengths are exceeded.

## Warning

Using the same table as source and destination table in versions earlier than 5.04, might produce unexpected behavior, so use with care.

This opcode works at k-rate (this means that every k-pass the vectors are subtracted). There's an i-rate

version of this opcode called *vsubv\_i*.

## Note

Please note that the *elements* argument has changed in version 5.03 from i-rate to k-rate. This will change the opcode's behavior in the unusual cases where the i-rate variable *ielements* is changed inside the instrument, for example in:

```
instr 1
ielements =      10
              vadd    1, 1, ielements
ielements =      20
              vadd    2, 1, ielements
turnoff
endin
```

All these operators (*vaddv*, *vsubv*, *vmultv*, *vdivv*, *vpowv*, *vexpv*, *vcopy* and *vmap*) are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2*, etc.

## Examples

Here is an example of the *vsubv* opcode. It uses the file *vsubv.csd* [examples/vsubv.csd].

### Example 1033. Example of the *vsubv* opcode.

## vsubv\_i

vsubv\_i — Performs subtraction between two vectorial control signals at init time.

## Description

Performs subtraction between two vectorial control signals at init time.

## Syntax

```
vsubv_i ifn1, ifn2, ielements [, idstoffset] [, isrcoffset]
```

## Initialization

*ifn1* - number of the table hosting the first vector to be processed

*ifn2* - number of the table hosting the second vector to be processed

*ielements* - number of elements of the two vectors

*idstoffset* - index offset for the destination (ifn1) table (Default=0)

*isrcoffset* - index offset for the source (ifn2) table (Default=0)

## Performance

*vsubv\_i* subtracts two vectorial control signals, that is, each element of ifn2 is subtracted from the corresponding element of ifn1. Each vectorial signal is hosted by a table (ifn1 and ifn2). The number of elements contained in both vectors must be the same.

The result is a new vectorial control signal that overrides old values of ifn1. If you want to keep the old ifn1 vector, use *vcopy\_i* opcode to copy it in another table. You can use *idstoffset* and *isrcoffset* to specify vectors in any location of the tables.

Negative values for *idstoffset* and *isrcoffset* are acceptable. If *idstoffset* is negative, the out of range section of the vector will be discarded. If *isrcoffset* is negative, the out of range elements will be assumed to be 0 (i.e. the destination elements will not be changed). If elements for the destination vector are beyond the size of the table (including guard point), these elements are discarded (i.e. elements do not wrap around the tables). If elements for the source vector are beyond the table length, these elements are taken as 0 (i.e. the destination vector will not be changed for these elements).

### Warning

Using the same table as source and destination table in versions earlier than 5.04, might produce unexpected behavior, so use with care.

This opcode works at init time. There's an k-rate version of this opcode called *vsubv*.

All these operators (*vaddv\_i*, *vsubv\_i*, *vmultv\_i*, *vdivv\_i*, *vpowv\_i*, *vexpv\_i*, *vcopy* and *vmap*) are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2* etc.

# vtable1k

vtable1k — Read a vector (several scalars simultaneously) from a table.

## Description

This opcode reads vectors from tables at k-rate.

## Syntax

```
vtable1k  kfn,kout1 [, kout2, kout3, .... , koutN ]
```

## Performance

*kfn* - table number

*kout1*...*koutN* - output vector elements

*vtable1k* is a reduced version of *vtablek*, it only allows to access the first vector (it is equivalent to *vtablek* with *kndx* = zero, but a bit faster). It is useful to easily and quickly convert a set of values stored in a table into a set of k-rate variables to be used in normal opocodes, instead of using individual *table* opcodes for each value.

### Note

*vtable1k* is an unusual opcode as it produces its output on the right side arguments of the opcode.

## Examples

Here is an example of the vtable1k opcode. It uses the files *vtable1k.csd* [examples/vtable1k.csd].

### Example 1034. Example of the vtable1k opcode.

# vtablei

vtablei — Read vectors (from tables -or arrays of vectors).

## Description

This opcode reads vectors from tables.

## Syntax

```
vtablei  indx, ifn, interp, ixmode, iout1 [, iout2, iout3, .... , ioutN ]
```

## Initialization

*indx* - Index into f-table, either a positive number range matching the table length (ixmode = 0) or a 0 to 1 range (ixmode != 0).

*ifn* - table number

*iout1...ioutN* - output vector elements

*ixmode* - index data mode. The default value is 0.

== 0 index is treated as a raw table location,

== 1 index is normalized (0 to 1).

*interp* - vtable (vector table) family of opcodes allows the user to switch between interpolated or non-interpolated output by means of the interp argument.

## Performance

This opcode is useful in all cases in which one needs to access sets of values associated to unique indexes (for example, multi-channel samples, STFT bin frames, spectral formants, p-field based scores etc.). The number of elements of each vector (length of the vector) is determined by the number of optional arguments on the right (iout1, iout2, iout3, ..., ioutN).

*vtable* (vector table) family of opcodes allows the user to switch between interpolated or non-interpolated output by means of the interp argument.

Notice that no wrap nor limit mode is implemented. So, if an index attempt to access to a zone not allocated by the table, Csound will probably crash. However this drawback can be easily avoided by using wrap or limit opcodes applied to indexes before using vtable, in order to correct eventual out-of-range values.

### Note

Notice that *vtablei*'s output arguments are placed at the right of the opcode name, differently from usual (this style is already used in other opcodes using undefined lists of output arguments such as *fin* or *trigseq*).

## Examples

Here is an example of the vtablei opcode. It uses the files *vtablei.csd* [examples/vtablei.csd]

# vtablek

vtablek — Read vectors (from tables -or arrays of vectors).

## Description

This opcode reads vectors from tables at k-rate.

## Syntax

```
vtablek kndx, kfn, kinterp, ixmode, kout1 [, kout2, kout3, .... , koutN ]
```

## Initialization

*ixmode* - index data mode. The default value is 0.

== 0 index is treated as a raw table location,

== 1 index is normalized (0 to 1).

*kinterp* - switch between interpolated or non-interpolated output. 0 -> non-interpolation , non-zero -> interpolation activated

## Performance

*kndx* - Index into f-table, either a positive number range matching the table length (ixmode = 0) or a 0 to 1 range (ixmode != 0).

*kfn* - table number

*kout1*...*koutN* - output vector elements

This opcode is useful in all cases in which one needs to access sets of values associated to unique indexes (for example, multi-channel samples, STFT bin frames, spectral formants, p-field based scores etc.). The number of elements of each vector (length of the vector) is determined by the number of optional arguments on the right (kout1 , kout2, kout3, .... koutN).

*vtablek* allows the user to switch between interpolated or non-interpolated output at k-rate by means of *kinterp* argument.

*vtablek* allows also to switch the table number at k-rate (but this is possible only when vector frames of each used table have the same number of elements, otherwise unpredictable results could occur), as well as to choose indexing style (raw or normalized, see also *ixmode* argument of table opcode ).

Notice that no wrap nor limit mode is implemented. So, if an index attempt to access to a zone not allocated by the table, Csound will probably crash. However this drawback can be easily avoided by using wrap or limit opcodes applied to indexes before using vtable, in order to correct eventual out-of-range values.

### Note

Notice that *vtablek*'s output arguments are placed at the left of the opcode name, differently from usual (this style is already used in other opcodes using undefined lists of output argu-

ments such as *fin* or *trigseq*).

## Examples

# vtablea

vtablea — Read vectors (from tables -or arrays of vectors).

## Description

This opcode reads vectors from tables at a-rate.

## Syntax

```
vtablea andx, kfn, kinterp, ixmode, aout1 [, aout2, aout3, .... , aoutN ]
```

## Initialization

*ixmode* - index data mode. The default value is 0.

== 0 index is treated as a raw table location,

== 1 index is normalized (0 to 1).

## Performance

*andx* - Index into f-table, either a positive number range matching the table length (ixmode = 0) or a 0 to 1 range (ixmode != 0).

*kfn* - table number

*kinterp* - switch between interpolated or non-interpolated output. 0 -> non-interpolation , non-zero -> interpolation activated

*aout1...aoutN* - output vector elements

This opcode is useful in all cases in which one needs to access sets of values associated to unique indexes (for example, multi-channel samples, STFT bin frames, spectral formants, p-field based scores etc.). The number of elements of each vector (length of the vector) is determined by the number of optional arguments on the right (aout1 , aout2, aout3, .... aoutN).

**vtablea** allows the user to switch between interpolated or non-interpolated output at k-rate by means of *kinterp* argument.

**vtablea** allows also to switch the table number at k-rate (but this is possible only when vector frames of each used table have the same number of elements, otherwise unpredictable results could occur), as well as to choose indexing style (raw or normalized, see also *ixmode* argument of table opcode ).

Notice that no wrap nor limit mode is implemented. So, if an index attempt to access to a zone not allocated by the table, Csound will probably crash. However this drawback can be easily avoided by using wrap or limit opcodes applied to indexes before using vtablea, in order to correct eventual out-of-range values.

### Note

Notice that *vtablea*'s output arguments are placed at the right of the opcode name, differently from usual (this style is already used in other opcodes using undefined lists of output

arguments such as *fin* or *trigseq*).

# **vtabi**

**vtabi** — Read vectors (from tables -or arrays of vectors).

## **Description**

This opcode reads vectors from tables.

## **Syntax**

```
vtabi indx, ifn, iout1 [, iout2, iout3, .... , ioutN ]
```

## **Initialization**

*indx* - Index into f-table, either a positive number range matching the table length

*ifn* - table number

*iout1...ioutN* - output vector elements

## **Performance**

This opcode is useful in all cases in which one needs to access sets of values associated to unique indexes (for example, multi-channel samples, STFT bin frames, spectral formants, p-field based scores etc.). The number of elements of each vector (length of the vector) is determined by the number of optional arguments on the right (*iout1*, *iout2*, *iout3*, ..., *ioutN*).

Notice that no wrap nor limit mode is implemented. So, if an index attempt to access to a zone not allocated by the table, Csound will probably crash. However this drawback can be easily avoided by using wrap or limit opcodes applied to indexes before using *vtabi*, in order to correct eventual out-of-range values.

The **vtab** family is similar to **vtable**, but is much faster because interpolation is not available, table number cannot be changed after initialization, and only raw indexing is supported.

### **Note**

Notice that *vtabi*'s output arguments are placed at the right of the opcode name, differently from usual (this style is already used in other opcodes using undefined lists of output arguments such as *fin* or *trigseq*).

## **Examples**

For an example of the *vtabi* opcode usage, see *vtablei*.

## **See also**

# vtabk

vtabk — Read vectors (from tables -or arrays of vectors).

## Description

This opcode reads vectors from tables at k-rate.

## Syntax

```
vtabk  kndx, ifn, kout1 [, kout2, kout3, .... , koutN ]
```

## Initialization

*ifn* - table number

## Performance

*kndx* - Index into f-table, either a positive number range matching the table length

*kout1*...*koutN* - output vector elements

This opcode is useful in all cases in which one needs to access sets of values associated to unique indexes (for example, multi-channel samples, STFT bin frames, spectral formants, p-field based scores etc.) . The number of elements of each vector (length of the vector) is determined by the number of optional arguments on the right (*kout1*, *kout2*, *kout3*, .... *koutN*).

Notice that no wrap nor limit mode is implemented. So, if an index attempt to access to a zone not allocated by the table, Csound will probably crash. However this drawback can be easily avoided by using wrap or limit opcodes applied to indexes before using *vtabk*, in order to correct eventual out-of-range values.

The **vtab** family is similar to **vtable**, but is much faster because interpolation is not available, table number cannot be changed after initialization, and only raw indexing is supported.

### Note

Notice that *vtabk*'s output arguments are placed at the right of the opcode name, differently from usual (this style is already used in other opcodes using undefined lists of output arguments such as *fin* or *trigseq*).

## Examples

For an example of the vtabk opcode usage, see *vtablek*.

# vtaba

vtaba — Read vectors (from tables -or arrays of vectors).

## Description

This opcode reads vectors from tables at a-rate.

## Syntax

```
vtaba andx, ifn, aout1 [, aout2, aout3, .... , aoutN ]
```

## Initialization

*ifn* - table number

## Performance

*andx* - Index into f-table, either a positive number range matching the table length

*aout1*...*aoutN* - output vector elements

This opcode is useful in all cases in which one needs to access sets of values associated to unique indexes (for example, multi-channel samples, STFT bin frames, spectral formants, p-field based scores etc.). The number of elements of each vector (length of the vector) is determined by the number of optional arguments on the right (*aout1*, *aout2*, *aout3*, ..., *aoutN*).

Notice that no wrap nor limit mode is implemented. So, if an index attempt to access to a zone not allocated by the table, Csound will probably crash. However this drawback can be easily avoided by using wrap or limit opcodes applied to indexes before using *vtaba*, in order to correct eventual out-of-range values.

The **vtab** family is similar to the **vtable** family, but is much faster because interpolation is not available, table number cannot be changed after initialization, and only raw indexing is supported.

### Note

Notice that *vtaba*'s output arguments are placed at the right of the opcode name, differently from usual (this style is already used in other opcodes using undefined lists of output arguments such as *fin* or *trigseq*).

## Examples

The usage of *vtaba* is similar to *vtablek*.

# vtabwi

vtabwi — Write vectors (to tables -or arrays of vectors).

## Description

This opcode writes vectors to tables at init time.

## Syntax

```
vtabwi  indx, ifn, inarg1 [, inarg2, inarg3 , .... , inargN ]
```

## Initialization

*indx* - Index into f-table, a positive number range matching the table length

*ifn* - table number

*inarg1...inargN* - input vector elements

## Performance

This opcode is useful in all cases in which one needs to write sets of values associated to unique indexes (for example, multi-channel samples, STFT bin frames, spectral formants, p-field based scores etc.). The number of elements of each vector (length of the vector) is determined by the number of optional arguments on the right (*inarg1, inarg2, inarg3, .... inargN*).

Notice that no wrap nor limit mode is implemented. So, if an index attempt to access to a zone not allocated by the table, Csound will probably crash. However this drawback can be easily avoided by using wrap or limit opcodes applied to indexes before using *vtabwi*, in order to correct eventual out-of-range values.

# vtabwk

vtabwk — Write vectors (to tables -or arrays of vectors).

## Description

This opcode writes vectors to tables at k-rate.

## Syntax

```
vtabwk  kndx, ifn, kinarg1 [, kinarg2, kinarg3 , .... , kinargN ]
```

## Initialization

*ifn* - table number

## Performance

*knidx* - Index into f-table, a positive number range matching the table length

*kinarg1...kinargN* - input vector elements

This opcode is useful in all cases in which one needs to write sets of values associated to unique indexes (for example, multi-channel samples, STFT bin frames, spectral formants, p-field based scores etc.) . The number of elements of each vector (length of the vector) is determined by the number of optional arguments on the right (*kinarg1, kinarg2, kinarg3, .... kinargN*).

Notice that no wrap nor limit mode is implemented. So, if an index attempt to access to a zone not allocated by the table, Csound will probably crash. However this drawback can be easily avoided by using wrap or limit opcodes applied to indexes before using *vtabwk*, in order to correct eventual out-of-range values.

# vtabwa

vtabwa — Write vectors (to tables -or arrays of vectors).

## Description

This opcode writes vectors to tables at a-rate.

## Syntax

```
vtabwa andx, ifn, ainarg1 [, ainarg2, ainarg3 , .... , ainargN ]
```

## Initialization

*ifn* - table number

## Performance

*andx* - Index into f-table, a positive number range matching the table length

*ainarg1...ainargN* - input vector elements

This opcode is useful in all cases in which one needs to write sets of values associated to unique indexes (for example, multi-channel samples, STFT bin frames, spectral formants, p-field based scores etc.). The number of elements of each vector (length of the vector) is determined by the number of optional arguments on the right (*ainarg1, ainarg2, ainarg3, .... ainargN*).

Notice that no wrap nor limit mode is implemented. So, if an index attempt to access to a zone not allocated by the table, Csound will probably crash. However this drawback can be easily avoided by using wrap or limit opcodes applied to indexes before using *vtabwa*, in order to correct eventual out-of-range values.

# vwrap

vwrap — Limiting and Wrapping Vectorial Signals

## Description

Wraps elements of vectorial control signals.

## Syntax

```
vwrap ifn, kmin, kmax, ielements
```

## Initialization

*ifn* - number of the table hosting the vector to be processed

*ielements* - number of elements of the vector

## Performance

*kmin* - minimum threshold value

*kmax* - maximum threshold value

*vwrap* wraps around each element of corresponding vector if it exceeds low or high thresholds.

These opcodes are similar to *limit*, *wrap* and *mirror*, but operate with a vectorial signal instead of with a scalar signal.

Result overrides old values of *ifn1*, if these are out of min/max interval. If you want to keep input vector, use *vcopy* opcode to copy it in another table.

All these opcodes are designed to be used together with other opcodes that operate with vectorial signals such as *vcella*, *adsynt*, *adsynt2* etc.

# waveset

waveset — A simple time stretch by repeating cycles.

## Description

A simple time stretch by repeating cycles.

## Syntax

```
ares waveset ain, krep [, ilen]
```

## Initialization

*ilen* (optional, default=0) -- the length (in samples) of the audio signal. If *ilen* is set to 0, it defaults to half the given note length (p3).

## Performance

*ain* -- the input audio signal.

*krep* -- the number of times the cycle is repeated.

The input is read and each complete cycle (two zero-crossings) is repeated *krep* times.

There is an internal buffer as the output is clearly slower than the input. Some care is taken if the buffer is too short, but there may be strange effects.

## Examples

Here is an example of the waveset opcode. It uses the file *waveset.csd* [examples/waveset.csd].

### Example 1039. Example of the waveset opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# websocket

`websocket` — Read and write signals and arrays using a websocket connection.

## Description

`websocket` reads and writes  $N$  signals and arrays using a websocket connection.

## Syntax

```
xout1[, xout2, xout3, ..., xoutN] websocket iport, xin1[, xin2, xin3, ..., xinN]
```

## Initialization

*iport* the local web port to read/write data.

## Performance

## Performance

*xout1,... xoutN* -- The output variables which contain data received from a websocket. On the web side the websocket must send data using a protocol name that matches the output variable name e.g. "ksignal" for a k-rate variable. If an array is intended to be received from a websocket it must be first initialised before being used as an output to the opcode. Otherwise the opcode doesn't know what size data to expect from the websocket. When sending data to a websocket from the web page it must be sent as a 32 or 64 bit array, depending on the build of Csound that is being used.

*xin1,... xinN* -- The input variables which contain data which is sent to a websocket. On the web side the websocket receives data using a protocol name that matches the input variable name e.g. "ksignal" for a k-rate variable. When receiving data from a websocket on the web page it must be read as a 32 or 64 bit array, depending on the build of Csound that is being used.

### Note

The total number of input and output arguments is limited to 20.

A-rate variables must be send and received as arrays that are *ksmps* samples large. A-rate arrays similarly are sent and received as *ksmps* by the number of elements in the array. K-rate variables are sent and received as a single element array. K-rate arrays are sent and received as arrays with matching numbers of elements.

## Examples

Here is a simple example of the websocket opcode. It uses the file `websocket.csd` [examples/websocket.csd] and `websocket.html` [examples/websocket.html].

### Example 1040. Example of the websocket opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command

line flags.

# weibull

**weibull** — Weibull distribution random number generator (positive values only).

## Description

Weibull distribution random number generator (positive values only). This is an x-class noise generator

## Syntax

```
ares weibull ksigma, ktau  
  
ires weibull ksigma, ktau  
  
kres weibull ksigma, ktau
```

## Performance

*ksigma* -- scales the spread of the distribution.

*ktau* -- if greater than one, numbers near *ksigma* are favored. If smaller than one, small values are favored. If t equals 1, the distribution is exponential. Outputs only positive numbers.

For more detailed explanation of these distributions, see:

1. C. Dodge - T.A. Jerse 1985. Computer music. Schirmer books. pp.265 - 286
2. D. Lorrain. A panoply of stochastic cannons. In C. Roads, ed. 1989. Music machine . Cambridge, Massachusetts: MIT press, pp. 351 - 379.

## Examples

Here is an example of the weibull opcode. It uses the file *weibull.csd* [examples/weibull.csd].

### Example 1041. Example of the weibull opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# wgbow

wgbow — Creates a tone similar to a bowed string.

## Description

Audio output is a tone similar to a bowed string, using a physical model developed from Perry Cook, but re-coded for Csound.

## Syntax

```
ares wgbow kamp, kfreq, kpres, krat, kvibf, kvamp \
[, ifn] [, iminfreq]
```

## Initialization

*ifn* -- optional table of shape of vibrato, defaults to a sine table.

*iminfreq* (optional) -- lowest frequency at which the instrument will play. If it is omitted it is taken to be the same as the initial *kfreq*. If *iminfreq* is negative, initialization will be skipped.

## Performance

A note is played on a string-like instrument, with the arguments as below.

*kamp* -- amplitude of note.

*kfreq* -- frequency of note played.

*kpres* -- a parameter controlling the pressure of the bow on the string. Values should be about 3. The useful range is approximately 1 to 5.

*krat* -- the position of the bow along the string. Usual playing is about 0.127236. The suggested range is 0.025 to 0.23.

*kvibf* -- frequency of vibrato in Hertz. Suggested range is 0 to 12

*kvamp* -- amplitude of the vibrato

## Examples

Here is an example of the wgbow opcode. It uses the file *wgbow.csd* [examples/wgbow.csd].

### Example 1042. Example of the wgbow opcode.

# wgbowedbar

wgbowedbar — A physical model of a bowed bar.

## Description

A physical model of a bowed bar, belonging to the Perry Cook family of waveguide instruments.

## Syntax

```
ares wgbowedbar kamp, kfreq, kpos, kbowpres, kgain [, iconst] [, itvel] \
[, ibowpos] [, ilow]
```

## Initialization

*iconst* (optional, default=0) -- an integration constant. Default is zero.

*itvel* (optional, default=0) -- either 0 or 1. When *itvel* = 0, the bow velocity follows an ADSR style trajectory. When *itvel* = 1, the value of the bow velocity decays in an exponentially.

*ibowpos* (optional, default=0) -- the position on the bow, which affects the bow velocity trajectory.

*ilow* (optional, default=0) -- lowest frequency required

## Performance

*kamp* -- amplitude of signal

*kfreq* -- frequency of signal

*kpos* -- position of the bow on the bar, in the range 0 to 1

*kbowpres* -- pressure of the bow (as in *wgbowed*)

*kgain* -- gain of filter. A value of about 0.809 is suggested.

## Examples

Here is an example of the wgbowedbar opcode. It uses the file *wgbowedbar.csd* [examples/wgbowedbar.csd].

### Example 1043. Example of the wgbowedbar opcode.

# wgbrass

wgbrass — Creates a tone related to a brass instrument.

## Description

Audio output is a tone related to a brass instrument, using a physical model developed from Perry Cook, but re-coded for Csound.

## Syntax

```
ares wgbrass kamp, kfreq, ktens, iatt, kvibf, kvamp \
[, ifn] [, iminfreq]
```

## Initialization

*iatt* -- time taken to reach full pressure

*ifn* -- optional table of shape of vibrato, defaults to a sine table.

*iminfreq* -- lowest frequency at which the instrument will play. If it is omitted it is taken to be the same as the initial *kfreq*. If *iminfreq* is negative, initialization will be skipped.

## Performance

A note is played on a brass-like instrument, with the arguments as below.

*kamp* -- Amplitude of note.

*kfreq* -- Frequency of note played.

*ktens* -- lip tension of the player. Suggested value is about 0.4

*kvibf* -- frequency of vibrato in Hertz. Suggested range is 0 to 12

*kvamp* -- amplitude of the vibrato

### NOTE

This is rather poor, and at present uncontrolled. Needs revision, and possibly more parameters.

## Examples

Here is an example of the wgbrass opcode. It uses the file *wgbrass.csd* [examples/wgbrass.csd].

### Example 1044. Example of the wgbrass opcode.

# wgclar

wgclar — Creates a tone similar to a clarinet.

## Description

Audio output is a tone similar to a clarinet, using a physical model developed from Perry Cook, but re-coded for Csound.

## Syntax

```
ares wgclar kamp, kfreq, kstiff, \
      iatt, idetk, kngain, kvibf, kvamp [, ifn] [, iminfreq]
```

## Initialization

*iatt* -- time in seconds to reach full blowing pressure. 0.1 seems to correspond to reasonable playing. A longer time gives a definite initial wind sound.

*idetk* -- time in seconds taken to stop blowing. 0.1 is a smooth ending

*ifn* (optional) -- table of shape of vibrato, defaults to the usual sine table.

*iminfreq* (optional) -- lowest frequency at which the instrument will play. If it is omitted it is taken to be the same as the initial *kfreq*. If *iminfreq* is negative, initialization will be skipped.

## Performance

A note is played on a clarinet-like instrument, with the arguments as below.

*kamp* -- Amplitude of note.

*kfreq* -- Frequency of note played.

*kstiff* -- a stiffness parameter for the reed. Values should be negative, and about -0.3. The useful range is approximately -0.44 to -0.18.

*kngain* -- amplitude of the noise component, about 0 to 0.5

*kvibf* -- frequency of vibrato in Hertz. Suggested range is 0 to 12

*kvamp* -- amplitude of the vibrato

## Examples

Here is an example of the wgclar opcode. It uses the file *wgclar.csd* [examples/wgclar.csd].

### Example 1045. Example of the wgclar opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# wgflute

wgflute — Creates a tone similar to a flute.

## Description

Audio output is a tone similar to a flute, using a physical model developed from Perry Cook, but re-coded for Csound.

## Syntax

```
ares wgflute kamp, kfreq, kjet, iatt,  
      idetk, kngain, kvibf, kvamp [, ifn] [, iminfreq] [, ijetr] [, iendrf]
```

## Initialization

*iatt* -- time in seconds to reach full blowing pressure. 0.1 seems to correspond to reasonable playing.

*idetk* -- time in seconds taken to stop blowing. 0.1 is a smooth ending

*ifn* (optional) -- table of shape of vibrato, defaults to the usual sine table.

*iminfreq* (optional) -- lowest frequency at which the instrument will play. If it is omitted it is taken to be the same as the initial kfreq. If *iminfreq* is negative, initialization will be skipped.

*ijetr* (optional, default=0.5) -- amount of reflection in the breath jet that powers the flute. Default value is 0.5.

*iendrf* (optional, default=0.5) -- reflection coefficient of the breath jet. Default value is 0.5. Both *ijetr* and *iendrf* are used in the calculation of the pressure differential.

## Performance

*kamp* -- Amplitude of note.

*kfreq* -- Frequency of note played. While it can be varied in performance, I have not tried it.

*kjet* -- a parameter controlling the air jet. Values should be positive, and about 0.3. The useful range is approximately 0.08 to 0.56.

*kngain* -- amplitude of the noise component, about 0 to 0.5

*kvibf* -- frequency of vibrato in Hertz. Suggested range is 0 to 12

*kvamp* -- amplitude of the vibrato

## Examples

Here is an example of the wgflute opcode. It uses the file *wgflute.csd* [examples/wgflute.csd].

# wgpluck

wgpluck — A high fidelity simulation of a plucked string.

## Description

A high fidelity simulation of a plucked string, using interpolating delay-lines.

## Syntax

```
ares wgpluck icps, iamp, kpick, iplk, idamp, ifilt, axcite
```

## Initialization

*icps* -- frequency of plucked string

*iamp* -- amplitude of string pluck

*iplk* -- point along the string, where it is plucked, in the range of 0 to 1. 0 = no pluck

*idamp* -- damping of the note. This controls the overall decay of the string. The greater the value of *idamp*, the faster the decay. Negative values will cause an increase in output over time.

*ifilt* -- control the attenuation of the filter at the bridge. Higher values cause the higher harmonics to decay faster.

## Performance

*kpick* -- proportion of the way along the point to sample the output.

*axcite* -- a signal which excites the string.

A string of frequency *icps* is plucked with amplitude *iamp* at point *iplk*. The decay of the virtual string is controlled by *idamp* and *ifilt* which simulate the bridge. The oscillation is sampled at the point *kpick*, and excited by the signal *axcite*.

## Examples

The following example produces a moderately long note with rapidly decaying upper partials. It uses the file *wgpluck.csd* [examples/wgpluck.csd].

### Example 1047. An example of the wgpluck opcode.

# wgpluck2

wgpluck2 — Physical model of the plucked string.

## Description

*wgpluck2* is an implementation of the physical model of the plucked string, with control over the pluck point, the pickup point and the filter. Based on the Karplus-Strong algorithm.

## Syntax

```
ares wgpluck2 iplk, kamp, icps, kpick, krefl
```

## Initialization

*iplk* -- The point of pluck is *iplk*, which is a fraction of the way up the string (0 to 1). A pluck point of zero means no initial pluck.

*icps* -- The string plays at *icps* pitch.

## Performance

*kamp* -- Amplitude of note.

*kpick* -- Proportion of the way along the string to sample the output.

*krefl* -- the coefficient of reflection, indicating the lossiness and the rate of decay. It must be strictly between 0 and 1 (it will complain about both 0 and 1).

## Examples

Here is an example of the wgpluck2 opcode. It uses the file *wgpluck2.csd* [examples/wgpluck2.csd].

### Example 1049. Example of the wgpluck2 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# wguide1

wguide1 — A simple waveguide model consisting of one delay-line and one first-order lowpass filter.

## Description

A simple waveguide model consisting of one delay-line and one first-order lowpass filter.

## Syntax

```
ares wguide1 asig, xfreq, kcutoff, kfeedback
```

## Performance

*asig* -- the input of excitation noise.

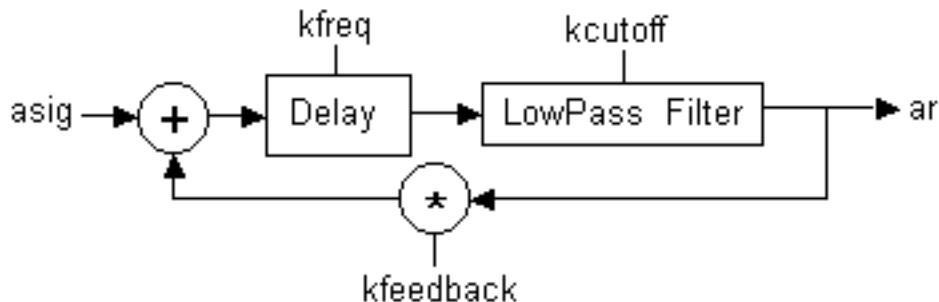

*xfreq* -- the frequency (i.e. the inverse of delay time) Changed to x-rate in Csound version 3.59.

*kcutoff* -- the filter cutoff frequency in Hz.

*kfeedback* -- the feedback factor.

*wguide1* is the most elemental waveguide model, consisting of one delay-line and one first-order low-pass filter.

Implementing waveguide algorithms as opcodes, instead of orc instruments, allows the user to set *kr* different than *sr*, allowing better performance particularly when using real-time.

wguide1.

## Examples

Here is an example of the wguide1 opcode. It uses the file *wguide1.csd* [examples/wguide1.csd].

### Example 1050. Example of the wguide1 opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# wguide2

wguide2 — A model of beaten plate consisting of two parallel delay-lines and two first-order lowpass filters.

## Description

A model of beaten plate consisting of two parallel delay-lines and two first-order lowpass filters.

## Syntax

```
ares wguide2 asig, xfreq1, xfreq2, kcutoff1, kcutoff2, \
      kfeedback1, kfeedback2
```

## Performance

*asig* -- the input of excitation noise

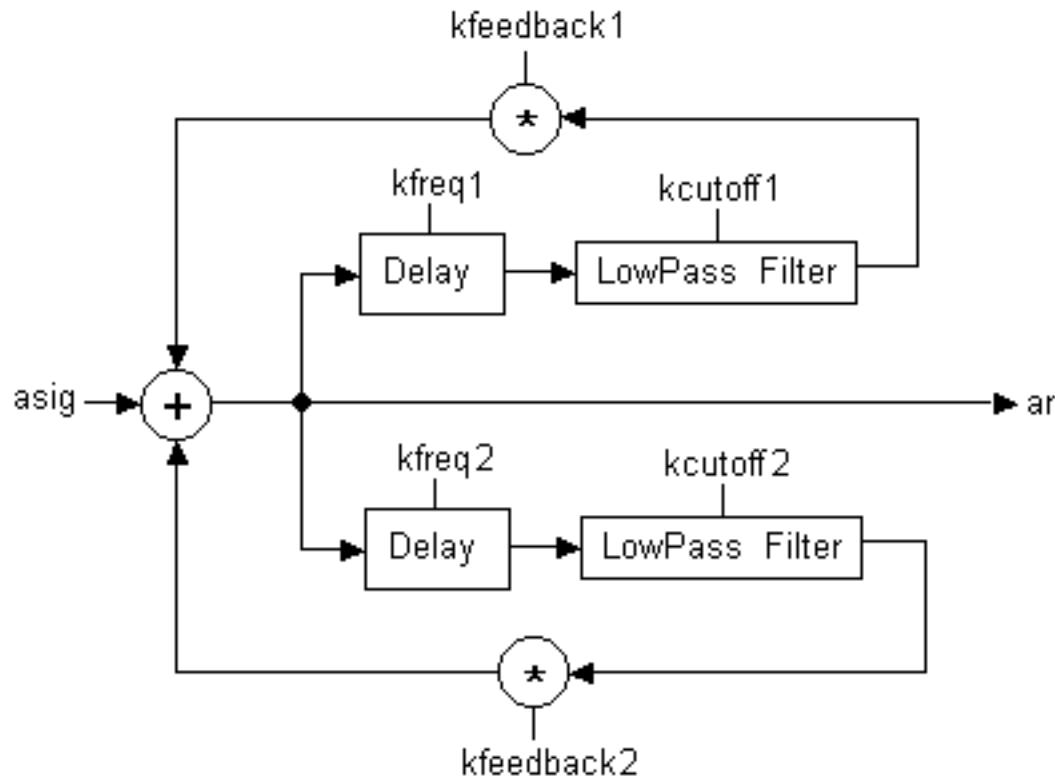

*xfreq1*, *xfreq2* -- the frequency (i.e. the inverse of delay time) Changed to x-rate in Csound version 3.59.

*kcutoff1*, *kcutoff2* -- the filter cutoff frequency in Hz.

*kfeedback1*, *kfeedback2* -- the feedback factor

*wguide2* is a model of beaten plate consisting of two parallel delay-lines and two first-order lowpass filters. The two feedback lines are mixed and sent to the delay again each cycle.

Implementing waveguide algorithms as opcodes, instead of orc instruments, allows the user to set *kr* different than *sr*, allowing better performance particularly when using real-time.

wguide2.

### Note

As a rule of thumb, to avoid making *wguide2* unstable, the sum of the two feedback values should be below 0.5.

## Examples

Here is an example of the *wguide2* opcode. It uses the file *wguide2.csd* [examples/wguide2.csd].

### Example 1051. Example of the *wguide2* opcode.

# while

while — A syntactic looping construction.

## Description

A syntactic looping construction.

## Syntax

```
while condition do  
... od
```

## Performance

The statements between the *do* and *od* form the body of a loop which is obeyed while the conditional remains true.

## Examples

Here is an example of the while construction. It uses the file *while.csd* [examples/while.csd].

### Example 1052. Example of the while opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# wiiconnect

wiiconnect — Reads data from a number of external Nintendo Wiimote controllers.

## Description

Opens and at control-rate polls up to four external Nintendo Wiimote controllers.

## Syntax

```
ires wiiconnect [itimeout, imaxnum]
```

## Initialization

*itimeout* -- integer number of seconds the system should wait for all Wiimotes to be connected. If not given it defaults to 10 seconds.

*imaxnum* -- maximum number of Wiimotes to locate. If not given it defaults to 4.

Initially each Wiimote has its numeric allocation indicated by lighting one of the four LEDs.

*ires* -- return value is 1 if sucess or zero on failure.

## Performance

### Note

Please note that these opcodes are currently only supported on Linux.

Every control cycle each Wiimote is polled for its status and position. These values are read by the *wiidata* opcode. The result returned is 1 in most cases, but will be zero if a Wiimote disconnects,

## Example

Here is an example of the wii opcodes. It uses the file *wii.csd* [examples/wii.csd].

### Example 1053. Example of the wii opcodes.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# wiidata

wiidata — Reads data fields from a number of external Nintendo Wiimote controllers.

## Description

Reads data fields from upto four external Nintendo Wiimote controllers.

## Syntax

```
kres wiidata kcontrol[, knum]
```

## Initialization

This opcode must be used in conjunction with a running *wiiconnect* opcode.

## Performance

### Note

Please note that these opcodes are currently only supported on Linux.

*kcontrol* -- the code for which control to read

*knum* -- the number of the which Wiimote to access, which defaults to the first one.

On each access a particular data item of the Wiimote is read. The currently implemented controls are given below, together with the macro name defined in the file *wii\_mac*:

0 (WII\_BUTTONS): returns a bit pattern for all buttons that were pressed.

1 (WII\_TWO): returns 1 if the button has just been pressed, or 0 otherwise.

2 (WII\_ONE): as above.

3 (WII\_B): as above.

4 (WII\_A): as above.

5 (WII\_MINUS): as above.

8 (WII\_HOME): as above.

9 (WII\_LEFT): as above.

10 (WII\_RIGHT): as above.

11 (WII\_DOWN): as above.

12 (WII\_UP): as above.

13 (WII\_PLUS): as above.

If the control number is 100 more than one of these button codes then the current state of the button is returned. Macros with names like WII\_S\_TWO etc are defined for this.

If the control number is 200 more than one of these button codes then the return value is 1 if the button is held and 0 otherwise. Macros with names like WII\_H\_TWO etc are defined for this.

If the control number is 300 more than one of these button codes then the value is 1 if the button has just been released, and 0 otherwise. Macros with names like WII\_R\_TWO etc are defined for this.

20 (WII\_PITCH): The pitch of the Wiimote. The value is in degrees between -90 and +90, unless modified by a *wiirange* call.

21 (WII\_ROLL): The roll of the Wiimote. The value is in degrees between -90 and +90, unless modified by a *wiirange* call.

23 (WII\_FORCE\_X): The force applied to the Wiimote in the three axes.

24 (WII\_FORCE\_Y):

25 (WII\_FORCE\_Z):

26 (WII\_FORCE\_TOTAL): The total magnitude of the force applied to the Wiimote.

27 (WII\_BATTERY): The percent of the battery that remains.

28 (WII\_NUNCHUK\_ANG): The angle of the nunchuk joystick in degrees.

29 (WII\_NUNCHUK\_MAG): The magnitude of the nunchuk joystick from neutral.

30 (WII\_NUNCHUK\_PITCH): The pitch of the nunchuk in degrees, in range -90 to +90 unless modified by a *wiirange* call.

31 (WII\_NUNCHUK\_ROLL): The roll of the nunchuk in degrees, in range -90 to +90 unless modified by a *wiirange* call.

33 (WII\_NUNCHUK\_Z): The state of the nunchuk Z button.

34 (WII\_NUNCHUK\_C): The state of the nunchuk C button.

35 (WII\_IR1\_X): The infrared pointing of the Wiimote.

36 (WII\_IR1\_Y):

37 (WII\_IR1\_Z):

# wiirange

`wiirange` — Sets scaling and range limits for certain Wiimote fields.

## Description

Sets scaling and range limits for certain Wiimote fields.

## Syntax

```
wiirange icontrol, iminimum, imaximum[, inum]
```

## Initialization

This opcode must be used in conjunction with a running *wiiconnect* opcode.

*icontrol* -- which control is to be scaled. This must be one of 20 (WII\_PITCH), 21 (WII\_ROLL), 30 (WII\_NUNCHUK\_PITCH), 31 (WII\_NUNCHUK\_ROLL).

*iminimum* -- minimum value for control.

*imaximum* -- maximum value for control.

### Note

Please note that these opcodes are currently only supported on Linux.

## Examples

See the example for *wiiconnect*.

# wiisend

wiisend — Sends data to one of a number of external Nintendo Wiimote controllers.

## Description

Sends data to one of a number of external Nintendo Wiimote controllers.

## Syntax

```
kres wiisend kcontrol, kvalue[, knum]
```

## Initialization

This opcode must be used in conjunction with a running *wiiconnect* opcode.

## Performance

### Note

Please note that these opcodes are currently only supported on Linux.

*kcontrol* -- the code for which control to write.

*kvalue* -- the value to write to the control.

*knum* -- the number of the which Wiimote to access, which defaults to the first one (zero).

On each access a particular data item of the Wiimote is written. The currently implemented controls are given below, together with the macro name defined in the file *wii\_mac*:

3 (WII\_RUMBLE): starts or stops the Wiimote rumbling, depending on the value of *kvalue* (0 to stop, 1 to start).

4 (WII\_SET\_LEDS): set the four LED lights on the Wiimote to the binary representation of *kvalue*.

## Examples

See the example for *wiiconnect*.

# window

window — Applies a window to an array.

## Description

Applies a given window shape to a vector stored in an array. The output is an array with the windowed vector.

## Initialization

*itype* -- optional window type: 0 = Hamming, 1 = Hanning (von Hann) (defaults to 1).

## Syntax

```
kout[] window kin[], koff, itype]
```

## Performance

*kout[]* -- output array containing the windowed output. It will be created if it does not exist.

*kin[]* -- input array containing the input vector.

*koff* -- offset to make window start at position *koff* (non-negative only, defaults to 0).

## Examples

Here is an example of the window opcode. It uses the file *window.csd* [examples/window.csd].

### Example 1054. Example of the window opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# wrap

`wrap` — Wraps-around the signal that exceeds the low and high thresholds.

## Description

Wraps-around the signal that exceeds the low and high thresholds.

## Syntax

```
ares wrap asig, klow, khigh  
  
ires wrap isig, ilow, ihigh  
  
kres wrap ksig, klow, khigh
```

## Initialization

*isig* -- input signal  
*ilow* -- low threshold  
*ihigh* -- high threshold

## Performance

*xsig* -- input signal  
*klow* -- low threshold  
*khight* -- high threshold

*wrap* wraps-around the signal that exceeds the low and high thresholds.

This opcode is useful in several situations, such as table indexing or for clipping and modeling a-rate, i-rate or k-rate signals. *wrap* is also useful for wrap-around of table data when the maximum index is not a power of two (see *table* and *tablei*). Another use of *wrap* is in cyclical event repeating, with arbitrary cycle length.

## Examples

Here is an example of the *wrap* opcode. It uses the file *wrap.csd* [examples/wrap.csd].

### Example 1055. Example of the wrap opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# writescratch

writescratch — writes a value into the scratchpad of the instance of an instrument.

## Description

The *writescratch* opcode writes one of four scalar values to be stored in the instance of an instrument.

## Syntax

```
writescratchival[, index]
```

## Initialisation

*ival* -- variable to write.

*index* -- which value to write, defaulting to zero.

## Examples

Here is an example of the writescratch opcode. It uses the file *readscratch.csd* [examples/readscratch.csd].

### Example 1056. Example of the writescratch opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# wterrain

wterrain — A simple wave-terrain synthesis opcode.

## Description

A simple wave-terrain synthesis opcode.

## Syntax

```
aout wterrain kamp, kpch, k_xcenter, k_ycenter, k_xradius, k_yradius, \
    itabx, itaby
```

## Initialization

*itabx, itaby* -- The two tables that define the terrain.

## Performance

The output is the result of drawing an ellipse with axes *k\_xradius* and *k\_yradius* centered at (*k\_xcenter*, *k\_ycenter*), and traversing it at frequency *kpch*.

## Examples

Here is an example of the wterrain opcode. It uses the file *wterrain.csd* [examples/wterrain.csd].

### Example 1057. Example of the wterrain opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# xadsr

xadsr — Calculates the classical ADSR envelope.

## Description

Calculates the classical ADSR envelope

## Syntax

```
ares xadsr iatt, idec, islev, irel [, idel]
```

```
kres xadsr iatt, idec, islev, irel [, idel]
```

## Initialization

*iatt* -- duration of attack phase

*idec* -- duration of decay

*islev* -- level for sustain phase

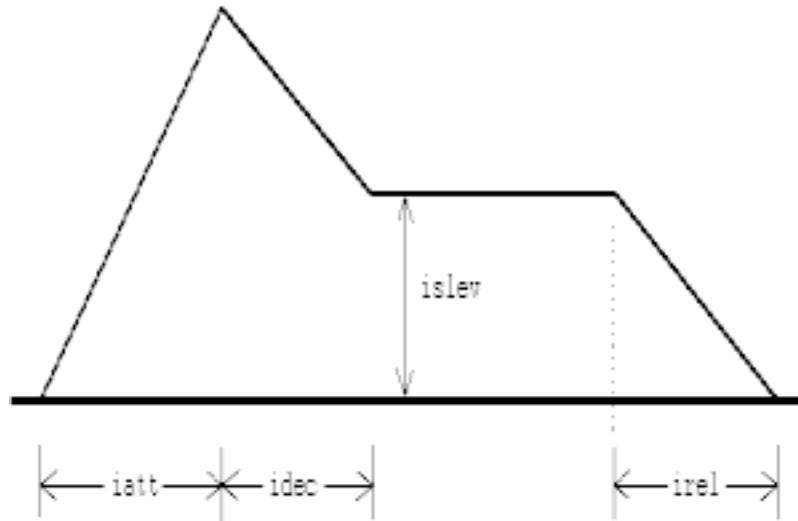

*irel* -- duration of release phase

*idel* -- period of zero before the envelope starts

## Performance

The envelope generated is the range 0 to 1 and may need to be scaled further, depending on the amplitude required. If using  $0dbfs = 1$ , scaling down will probably be required since playing more than one note might result in clipping. If not using  $0dbfs$ , scaling to a large amplitude (e.g. 32000) might be required.

The envelope may be described as:

Picture of an ADSR envelope.

The length of the sustain is calculated from the length of the note. This means *xadsr* is not suitable for use with MIDI events, use *mxadsr* instead. The opcode *xadsr* is identical to *adsr* except it uses exponential, rather than linear, line segments.

## Examples

Here is an example of the *xadsr* opcode. It uses the file *xadsr.csd* [examples/xadsr.csd].

### Example 1058. Example of the *xadsr* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# xin

`xin` — Passes variables to a user-defined opcode block,

## Description

The `xin` and `xout` opcodes copy variables to and from the opcode definition, allowing communication with the calling instrument.

The types of input and output variables are defined by the parameters *intypes* and *outtypes*.

### Notes

- `xin` and `xout` should be called only once, and `xin` should precede `xout`, otherwise an init error and deactivation of the current instrument may occur.
- These opcodes actually run only at i-time. Performance time copying is done by the user opcode call. This means that skipping `xin` or `xout` with `kgoto` has no effect, while skipping with `igoto` affects both init and performance time operation.

## Syntax

```
xinarg1 [, xinarg2] ... [xinargN] xin
```

## Performance

`xinarg1`, `xinarg2`, ... - input arguments. The number and type of variables must agree with the user-defined opcode's *intypes* declaration. However, `xin` does not check for incorrect use of init-time and control-rate variables.

The syntax of a user-defined opcode block is as follows:

```
opcode name, outtypes, intypes
xinarg1 [, xinarg2] [, xinarg3] ... [xinargN] xin
[setksmps iksmmps]
... the rest of the instrument's code.
xout xoutarg1 [, xoutarg2] [, xoutarg3] ... [xoutargN]
endop
```

The new opcode can then be used with the usual syntax:

```
[xinarg1] [, xinarg2] ... [xinargN] name [xoutarg1] [, xoutarg2] ... [xoutargN] [, iksmmps]
```

## Examples

See the example for the *opcode* opcode.

# xout

**xout** — Retrieves variables from a user-defined opcode block,

## Description

The *xin* and *xout* opcodes copy variables to and from the opcode definition, allowing communication with the calling instrument.

The types of input and output variables are defined by the parameters *intypes* and *outtypes*.

### Notes

- *xin* and *xout* should be called only once, and *xin* should precede *xout*, otherwise an init error and deactivation of the current instrument may occur.
- These opcodes actually run only at i-time. Performance time copying is done by the user opcode call. This means that skipping *xin* or *xout* with *kgoto* has no effect, while skipping with *igoto* affects both init and performance time operation.

## Syntax

```
xout xoutarg1 [, xoutarg2] ... [, xoutargN]
```

## Performance

*xoutarg1*, *xoutarg2*, ... - output arguments. The number and type of variables must agree with the user-defined opcode's *outtypes* declaration. However, *xout* does not check for incorrect use of init-time and control-rate variables.

The syntax of a user-defined opcode block is as follows:

```
opcode name, outtypes, intypes
xinarg1 [, xinarg2] [, xinarg3] ... [xinargN] xin
[setksmps iksmps]
... the rest of the instrument's code.
xout xoutarg1 [, xoutarg2] [, xoutarg3] ... [xoutargN]
endop
```

The new opcode can then be used with the usual syntax:

```
[xinarg1] [, xinarg2] ... [xinargN] name [xoutarg1] [, xoutarg2] ... [xoutargN] [, iksmps]
```

## Examples

See the example for the *opcode* opcode.

# xscanmap

xscanmap — Allows the position and velocity of a node in a scanned process to be read.

## Description

Allows the position and velocity of a node in a scanned process to be read.

## Syntax

```
kpos, kvel xscanmap iscan, kamp, kvamp [, iwhich]
```

## Initialization

*iscan* -- which scan process to read

*iwhich* (optional) -- which node to sense. The default is 0.

## Performance

*kamp* -- amount to amplify the *kpos* value.

*kvamp* -- amount to amplify the *kvel* value.

The internal state of a node is read. This includes its position and velocity. They are amplified by the *kamp* and *kvamp* values.

## Examples

Here is an example of the xscanmap opcode. It uses the file *xscanmap.csd* [examples/xscanmap.csd].

### Example 1059. Example of the xscanmap opcode.

# xscansmap

`xscansmap` — Allows the position and velocity of a node in a scanned process to be read.

## Description

Allows the position and velocity of a node in a scanned process to be read.

## Syntax

```
xscansmap kpos, kvel, iscan, kamp, kvamp [, iwhich]
```

## Initialization

*iscan* -- which scan process to read

*iwhich* (optional) -- which node to sense. The default is 0.

## Performance

*kpos* -- the node's position.

*kvel* -- the node's velocity.

*kamp* -- amount to amplify the *kpos* value.

*kvamp* -- amount to amplify the *kvel* value.

The internal state of a node is read. This includes its position and velocity. They are amplified by the *kamp* and *kvamp* values.

# xscans

xscans — Fast scanned synthesis waveform and the wavetable generator.

## Description

Experimental version of *scans*. Allows much larger matrices and is faster and smaller but removes some (unused?) flexibility. If liked, it will replace the older opcode as it is syntax compatible but extended.

## Syntax

```
ares xscans kamp, kfreq, ifntraj, id [, iorder]
```

## Initialization

*ifntraj* -- table containing the scanning trajectory. This is a series of numbers that contains addresses of masses. The order of these addresses is used as the scan path. It should not contain values greater than the number of masses, or negative numbers. See the *introduction to the scanned synthesis section*.

*id* -- If positive, the ID of the opcode. This will be used to point the scanning opcode to the proper waveform maker. If this value is negative, the absolute of this value is the wavetable on which to write the waveshape. That wavetable can be used later from an other opcode to generate sound. The initial contents of this table will be destroyed.

*iorder* (optional, default=0) -- order of interpolation used internally. It can take any value in the range 1 to 4, and defaults to 4, which is quartic interpolation. The setting of 2 is quadratic and 1 is linear. The higher numbers are slower, but not necessarily better.

## Performance

*kamp* -- output amplitude. Note that the resulting amplitude is also dependent on instantaneous value in the wavetable. This number is effectively the scaling factor of the wavetable.

*kfreq* -- frequency of the scan rate

## Matrix Format

The new matrix format is a list of connections, one per line linking point x to point y. There is no weight given to the link; it is assumed to be unity. The list is preceded by the line <MATRIX> and ends with a </MATRIX> line

For example, a circular string of 8 would be coded as

```
<MATRIX>
0 1
1 0
1 2
2 1
2 3
3 2
3 4
4 3
4 5
5 4
```

```
5 6
6 5
6 7
7 6
0 7
</MATRIX>
```

## Examples

Here is an example of the xscans opcode. It uses the file *xscans.csd* [examples/xscans.csd].

### Example 1060. Example of the xscans opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## Credits

Written by John ffitch.

New in version 4.20

# xscanu

xscanu — Compute the waveform and the wavetable for use in scanned synthesis.

## Description

Experimental version of *scanu*. Allows much larger matrices and is faster and smaller but removes some (unused?) flexibility. If liked, it will replace the older opcode as it is syntax compatible but extended.

## Syntax

```
xscanu init, irate, ifnvel, ifnmass, ifnstif, ifncentr, ifndamp, kmass, \
kstif, kcentr, kdamp, ileft, iringht, kpos, kstrength, ain, idisp, id
```

## Initialization

*init* -- the initial position of the masses. If this is a negative number, then the absolute of init signifies the table to use as a hammer shape. If init > 0, the length of it should be the same as the intended mass number, otherwise it can be anything.

*irate* -- update rate.

*ifnvel* -- the ftable that contains the initial velocity for each mass. It should have the same size as the intended mass number.

*ifnmass* -- ftable that contains the mass of each mass. It should have the same size as the intended mass number.

*ifnstif* --

- either an ftable that contains the spring stiffness of each connection. It should have the same size as the square of the intended mass number. The data ordering is a row after row dump of the connection matrix of the system.
- or a string giving the name of a file in the MATRIX format

*ifncentr* -- ftable that contains the centering force of each mass. It should have the same size as the intended mass number.

*ifndamp* -- the ftable that contains the damping factor of each mass. It should have the same size as the intended mass number.

*ileft* -- If init < 0, the position of the left hammer (ileft = 0 is hit at leftmost, ileft = 1 is hit at rightmost).

*iringht* -- If init < 0, the position of the right hammer (iringht = 0 is hit at leftmost, iringht = 1 is hit at rightmost).

*idisp* -- If 0, no display of the masses is provided.

*id* -- If positive, the ID of the opcode. This will be used to point the scanning opcode to the proper waveform maker. If this value is negative, the absolute of this value is the wavetable on which to write the waveshape. That wavetable can be used later from another opcode to generate sound. The initial con-

tents of this table will be destroyed.

## Performance

*kmass* -- scales the masses

*kstif* -- scales the spring stiffness

*kcentr* -- scales the centering force

*kdamp* -- scales the damping

*kpos* -- position of an active hammer along the string (*kpos* = 0 is leftmost, *kpos* = 1 is rightmost). The shape of the hammer is determined by *init* and the power it pushes with is *kstrngth*.

*kstrngth* -- power that the active hammer uses

*ain* -- audio input that adds to the velocity of the masses. Amplitude should not be too great.

## Matrix Format

The new matrix format is a list of connections, one per line linking point x to point y. There is no weight given to the link; it is assumed to be unity. The list is proceeded by the line <MATRIX> and ends with a </MATRIX> line

For example, a circular string of 8 would be coded as

```
<MATRIX>
0 1
1 0
1 2
2 1
2 3
3 2
3 4
4 3
4 5
5 4
5 6
5 6
6 5
6 7
7 6
0 7
</MATRIX>
```

## Examples

Here is an example of the *xscanu* opcode. It uses the file *xscanu.csd* [examples/xscanu.csd].

### Example 1061. Example of the *xscanu* opcode.

# xtratim

xtratim — Extend the duration of real-time generated events.

## Description

Extend the duration of real-time generated events and handle their extra life (Usually for usage along with *release* instead of *linenr*, *linsegr*, etc).

## Syntax

```
xtratim iextradur
```

## Initialization

*iextradur* -- additional duration of current instrument instance

## Performance

*xtratim* extends current MIDI-activated note duration by *iextradur* seconds after the corresponding noteoff message has deactivated the current note itself. It is usually used in conjunction with *release*. This opcode has no output arguments.

This opcode is useful for implementing complex release-oriented envelopes, whose duration is not known when the envelope starts (e.g. for real-time MIDI generated events).

## Examples

Here is a simple example of the xtratim opcode. It uses the file *xtratim.csd* [examples/xtratim.csd].

### Example 1062. Example of the xtratim opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

This example shows how to generate a release segment for an ADSR envelope after a MIDI noteoff is received, extending the duration with *xtratim* and using *release* to check whether the note is on the release phase.

```

e
</CsScore>
</CsoundSynthesizer>
```

Here is a more elaborate example of the `xtratim` opcode. It uses the file `xtratim-2.csd` [examples/xtratim-2.csd].

### Example 1063. More complex example of the `xtratim` opcode.

This example shows how to generate a release segment for an ADSR envelope after a MIDI noteoff is received, extending the duration with `xtratim` and using `release` to check whether the note is on the release phase. Two envelopes are generated simultaneously for the left and right channels.

# xyin

`xyin` — Sense the cursor position in an output window

## Description

Sense the cursor position in an output window. When `xyin` is called the position of the mouse within the output window is used to reply to the request. This simple mechanism does mean that only one `xyin` can be used accurately at once. The position of the mouse is reported in the output window.

## Syntax

```
kx, ky xyin iprd, ixmin, ixmax, iymin, iymax [, ixinit] [, iyinit]
```

## Initialization

*iprd* -- period of cursor sensing (in seconds). Typically .1 seconds.

*xmin, xmax, ymin, ymax* -- edge values for the x-y coordinates of a cursor in the input window.

*ixinit, iyinit* (optional) -- initial x-y coordinates reported; the default values are 0,0. If these values are not within the given min-max range, they will be coerced into that range.

## Performance

`xyin` samples the cursor x-y position in an input window every *iprd* seconds. Output values are repeated (not interpolated) at the k-rate, and remain fixed until a new change is registered in the window. There may be any number of input windows. This unit is useful for real-time control, but continuous motion should be avoided if *iprd* is unusually small.

### Note

Depending on your platform and distribution, you might need to enable displays using the `-displays` command line flag.

## Examples

Here is an example of the `xyin` opcode. It uses the file `xyin.csd` [examples/xyin.csd].

### Example 1064. Example of the xyin opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```

# zacl

zacl — Clears one or more variables in the za space.

## Description

Clears one or more variables in the za space.

## Syntax

```
zacl kfirst, klast
```

## Performance

*kfirst* -- first zk or za location in the range to clear.

*klast* -- last zk or za location in the range to clear.

*zacl* clears one or more variables in the za space. This is useful for those variables which are used as accumulators for mixing a-rate signals at each cycle, but which must be cleared before the next set of calculations.

## Examples

Here is an example of the zacl opcode. It uses the file *zacl.csd* [examples/zacl.csd].

### Example 1065. Example of the zacl opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# zakinit

`zakinit` — Establishes zak space.

## Description

Establishes zak space. Must be called only once.

## Syntax

```
zakinit isizea, isizek
```

## Initialization

*isizea* -- the number of audio rate locations for a-rate patching. Each location is actually an array which is *ksmps* long.

*isizek* -- the number of locations to reserve for floats in the zk space. These can be written and read at i- and k-rates.

## Performance

At least one location each is always allocated for both za and zk spaces. There can be thousands or tens of thousands za and zk ranges, but most pieces probably only need a few dozen for patching signals. These patching locations are referred to by number in the other zak opcodes.

To run *zakinit* only once, put it outside any instrument definition, in the orchestra file header, after *sr*, *kr*, *ksmps*, and *nchnls*.

### Note

Zak channels count from 0, so if you define 1 channel, the only valid channel is channel 0.

## Examples

Here is an example of the *zakinit* opcode. It uses the file *zakinit.csd* [examples/zakinit.csd].

### Example 1066. Example of the *zakinit* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## zamod

`zamod` — Modulates one a-rate signal by a second one.

## Description

Modulates one a-rate signal by a second one.

## Syntax

```
ares zamod asig, kzamod
```

## Performance

*asig* -- the input signal

*kzamod* -- controls which za variable is used for modulation. A positive value means additive modulation, a negative value means multiplicative modulation. A value of 0 means no change to *asig*.

*zamod* modulates one a-rate signal by a second one, which comes from a za variable. The location of the modulating variable is controlled by the i-rate or k-rate variable *kzamod*. This is the a-rate version of *zkmod*.

## Examples

Here is an example of the *zamod* opcode. It uses the file *zamod.csd* [examples/zamod.csd].

### Example 1067. Example of the zamod opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## zaw

**zaw** — Writes to a za variable at a-rate without mixing.

## Description

Writes to a za variable at a-rate without mixing.

## Syntax

```
zaw asig, kndx
```

## Performance

*asig* -- value to be written to the za location.

*kndx* -- points to the zk or za location to which to write.

*zaw* writes *asig* into the za variable specified by *kndx*.

These opcodes are fast, and always check that the index is within the range of zk or za space. If not, an error is reported, 0 is returned, and no writing takes place.

## Examples

Here is an example of the *zaw* opcode. It uses the file *zaw.csd* [examples/zaw.csd].

## zawm

**zawm** — Writes to a za variable at a-rate with mixing.

## Description

Writes to a za variable at a-rate with mixing.

## Syntax

```
zawm asig, kndx [, imix]
```

## Initialization

*imix* (optional, default=1) -- indicates if mixing should occur.

## Performance

*asig* -- value to be written to the za location.

*kndx* -- points to the zk or za location to which to write.

These opcodes are fast, and always check that the index is within the range of zk or za space. If not, an error is reported, 0 is returned, and no writing takes place.

*zawm* is a mixing opcode, it adds the signal to the current value of the variable. If no *imix* is specified, mixing always occurs. *imix* = 0 will cause overwriting like *ziw*, *zkw*, and *zaw*. Any other value will cause mixing.

*Caution:* When using the mixing opcodes *ziwm*, *zkwm*, and *zawm*, care must be taken that the variables mixed to, are zeroed at the end (or start) of each k- or a-cycle. Continuing to add signals to them, can cause their values to drift to astronomical figures.

One approach would be to establish certain ranges of zk or za variables to be used for mixing, then use *zkcl* or *zacl* to clear those ranges.

## Examples

Here is an example of the *zawm* opcode. It uses the file *zawm.csd* [examples/zawm.csd].

### Example 1071. Example of the *zawm* opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

## **zfilter2**

**zfilter2** — Performs filtering using a transposed form-II digital filter lattice with radial pole-shearing and angular pole-warping.

## **Description**

General purpose custom filter with time-varying pole control. The filter coefficients implement the following difference equation:

$$(1)*y(n) = b0*x[n] + b1*x[n-1] + \dots + bM*x[n-M] - a1*y[n-1] - \dots - aN*y[n-N]$$

the system function for which is represented by:

$$H(Z) = \frac{B(Z)}{A(Z)} = \frac{b_0 + b_1 Z^{-1} + \dots + b_M Z^{-M}}{1 + a_1 Z^{-1} + \dots + a_N Z^{-N}}$$

## **Syntax**

```
ares zfilter2 asig, kdamp, kfreq, iM, iN, ib0, ib1, ..., ibM, \
      ia1, ia2, ..., iaN
```

## **Initialization**

At initialization the number of zeros and poles of the filter are specified along with the corresponding zero and pole coefficients. The coefficients must be obtained by an external filter-design application such as Matlab and specified directly or loaded into a table via *GEN01*. With *zfilter2*, the roots of the characteristic polynomials are solved at initialization so that the pole-control operations can be implemented efficiently.

## **Performance**

The *filter2* opcodes perform filtering using a transposed form-II digital filter lattice with no time-varying control. *zfilter2* uses the additional operations of radial pole-shearing and angular pole-warping in the Z plane.

Pole shearing increases the magnitude of poles along radial lines in the Z-plane. This has the affect of altering filter ring times. The k-rate variable *kdamp* is the damping parameter. Positive values (0.01 to 0.99) increase the ring-time of the filter (hi-Q), negative values (-0.01 to -0.99) decrease the ring-time of the filter, (lo-Q).

Pole warping changes the frequency of poles by moving them along angular paths in the Z plane. This operation leaves the shape of the magnitude response unchanged but alters the frequencies by a constant factor (preserving 0 and p). The k-rate variable *kfreq* determines the frequency warp factor. Positive values (0.01 to 0.99) increase frequencies toward p and negative values (-0.01 to -0.99) decrease frequencies toward 0.

Since *filter2* implements generalized recursive filters, it can be used to specify a large range of general DSP algorithms. For example, a digital waveguide can be implemented for musical instrument modeling using a pair of *delayr* and *delayw* opcodes in conjunction with the *filter2* opcode.

## Examples

A controllable second-order IIR filter operating on an a-rate signal:

```
a1 zfilter2 asig, kdamp, kfreq, 1, 2, 1, ia1, ia2 ;; controllable a-rate IIR filter
```

# ziwm

ziwm — Writes to a zk variable to an i-rate variable with mixing.

## Description

Writes to a zk variable to an i-rate variable with mixing.

## Syntax

```
ziwm isig, indx [, imix]
```

## Initialization

*isig* -- initializes the value of the zk location.

*indx* -- points to the zk location location to which to write.

*imix* (optional, default=1) -- indicates if mixing should occur.

## Performance

*ziwm* is a mixing opcode, it adds the signal to the current value of the variable. If no *imix* is specified, mixing always occurs. *imix* = 0 will cause overwriting like *ziw*, *zkw*, and *zaw*. Any other value will cause mixing.

*Caution:* When using the mixing opcodes *ziwm*, *zkwm*, and *zawm*, care must be taken that the variables mixed to, are zeroed at the end (or start) of each k- or a-cycle. Continuing to add signals to them, can cause their values can drift to astronomical figures.

One approach would be to establish certain ranges of zk or za variables to be used for mixing, then use *zkcl* or *zocl* to clear those ranges.

## Examples

Here is an example of the ziwm opcode. It uses the file *ziwm.csd* [examples/ziwm.csd].

### Example 1074. Example of the ziwm opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# zkcl

zkcl — Clears one or more variables in the zk space.

## Description

Clears one or more variables in the zk space.

## Syntax

```
zkcl kfirst, klast
```

## Performance

*ksig* -- the input signal

*kfirst* -- first zk or za location in the range to clear.

*klast* -- last zk or za location in the range to clear.

*zkcl* clears one or more variables in the zk space. This is useful for those variables which are used as accumulators for mixing k-rate signals at each cycle, but which must be cleared before the next set of calculations.

## Examples

Here is an example of the zkcl opcode. It uses the file *zkcl.csd* [examples/zkcl.csd].

### Example 1075. Example of the zkcl opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# zkmod

**zkmod** — Facilitates the modulation of one signal by another.

## Description

Facilitates the modulation of one signal by another.

## Syntax

```
kres zkmod ksig, kzkmmod
```

## Performance

*ksig* -- the input signal

*kzkmmod* -- controls which zk variable is used for modulation. A positive value means additive modulation, a negative value means multiplicative modulation. A value of 0 means no change to *ksig*. *kzkmmod* can be i-rate or k-rate

*zkmod* facilitates the modulation of one signal by another, where the modulating signal comes from a zk variable. Either additive or multiplicative modulation can be specified.

## Examples

Here is an example of the zkmod opcode. It uses the file *zkmod.csd* [examples/zkmod.csd].

### Example 1076. Example of the zkmod opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# zkwm

zkwm — Writes to a zk variable at k-rate with mixing.

## Description

Writes to a zk variable at k-rate with mixing.

## Syntax

```
zkwm ksig, kndx [, imix]
```

## Initialization

*imix* (optional, default=1) -- indicates if mixing should occur.

## Performance

*ksig* -- value to be written to the zk location.

*kndx* -- points to the zk or za location to which to write.

*zkwm* is a mixing opcode, it adds the signal to the current value of the variable. If no *imix* is specified, mixing always occurs. *imix* = 0 will cause overwriting like *ziw*, *zkw*, and *zaw*. Any other value will cause mixing.

*Caution:* When using the mixing opcodes *ziwm*, *zkwm*, and *zawm*, care must be taken that the variables mixed to, are zeroed at the end (or start) of each k- or a-cycle. Continuing to add signals to them, can cause their values to drift to astronomical figures.

One approach would be to establish certain ranges of zk or za variables to be used for mixing, then use *zkcl* or *zacl* to clear those ranges.

## Examples

Here is an example of the zkwm opcode. It uses the file *zkwm.csd* [examples/zkwm.csd].

### Example 1079. Example of the zkwm opcode.

# Score Statements and GEN Routines

## Score Statements

The statements used in scores are:

- *a* - Advance score time by a specified amount
- *b* - Resets the clock
- *e* - Marks the end of the last section of the score
- *f* - Causes a *GEN subroutine* to place values in a stored function table
- *i* - Makes an instrument active at a specific time and for a certain duration
- *m* - Sets a named mark in the score
- *n* - Repeats a marked section
- *q* - Used to quiet an instrument
- *r* - Starts a repeated section
- *s* - Marks the end of a section
- *t* - Sets the tempo
- *v* - Provides for locally variable time warping of score events
- *x* - Skip the rest of the current section
- *y* - Set seed for random numbers, either from p1 or, if omitted, the clock
- *{* - Begins a non-sectional, nestable loop
- *}* - Ends a non-sectional, nestable loop

# a Statement (or Advance Statement)

a — Advance score time by a specified amount.

## Description

This causes score time to be advanced by a specified amount without producing sound samples.

## Syntax

a p1 p2 p3

## Performance

- p1 Carries no meaning. Usually zero.
- p2 Action time, in beats, at which advance is to begin.
- p3 Number of beats to advance without producing sound.
- p4 |
- p5 | These carry no meaning.
- p6 |
- .
- .

## Special Considerations

This statement allows the beat count within a score section to be advanced without generating intervening sound samples. This can be of use when a score section is incomplete (the beginning or middle is missing) and the user does not wish to generate and listen to a lot of silence.

p2, action time, and p3, number of beats, are treated as in *i statements*, with respect to sorting and modification by *t statements*.

An *a statement* will be temporarily inserted in the score by the Score Extract feature when the extracted segment begins later than the start of a Section. The purpose of this is to preserve the beat count and time count of the original score for the benefit of the peak amplitude messages which are reported on the user console.

Whenever an *a statement* is encountered by a performing orchestra, its presence and effect will be reported on the user's console.

## Examples

Here is an example of the *a statement*. It uses the file *a.csd* [examples/a.csd].

### Example 1080. Example of the *a* statement.

# b Statement

b Statement — This statement resets the clock.

## Description

This statement resets the clock.

## Syntax

**b** p1

## Performance

p1 -- Specifies how the clock is to be set.

## Special Considerations

p1 is the number of beats by which p2 values of subsequent *i statements* are modified. If p1 is positive, the clock is reset forward, and subsequent notes appear later, the number of beats specified by p1 being added to the note's p2. If p1 is negative, the clock is reset backward, and subsequent notes appear earlier, the number of beats specified by p1 being subtracted from the note's p2. There is no cumulative affect. The clock is reset with each *b statement*. If p1 = 0, the clock is returned to its original position, and subsequent notes appear at their specified p2.

## Examples

Here is an example of the b statement. It uses the file *b.csd* [examples/b.csd].

### Example 1081. Example of the b statement.

```

## Credits

Explanation suggested and example provided by Paul Winkler. (Csound Version 4.07)

# e Statement

*e* statement — This statement may be used to mark the end of the last section of the score.

## Description

This statement may be used to mark the end of the last section of the score.

## Syntax

```
e [time]
```

## Performance

The first p-field *time* is optional and if present determines the end time (length in beats) of the final section of the score. This time must be after the end of the last event otherwise it will have no effect. "Always on" instruments will end at the given time. Extending the section in this way is useful to avoid prematurely cutting off reverb tails or other effects.

## Special Considerations

The *e statement* is contextually identical to an *s statement*. Additionally, the *e statement* terminates all signal generation (including indefinite performance) and closes all input and output files.

If an *e statement* occurs before the end of a score, all subsequent score lines will be ignored.

The *e statement* is optional in a score file yet to be sorted. If a score file has no *e statement*, then Sort processing will supply one.

## Examples

Here is an example of the *e statement*. It uses the file *e.csd* [examples/e.csd].

### Example 1082. Example of the e statement.

# f Statement (or Function Table Statement)

**f** Statement (or Function Table Statement) — Causes a GEN subroutine to place values in a stored function table.

## Description

This causes a GEN subroutine to place values in a stored function table for use by instruments.

## Syntax

```
f p1  p2  p3  p4  p5 ... PMAX
```

## Performance

*p1* -- Table number by which the stored function will be known. A negative number requests that the table be destroyed.

*p2* -- Action time of function generation (or destruction) in beats.

*p3* -- Size of function table (i.e. number of points) Must be a power of 2, or a power-of-2 plus 1 if this number is positive. Maximum table size is 16777216 ( $2^{24}$ ) points.

*p4* -- Number of the GEN routine to be called (see *GEN ROUTINES*). A negative value will cause rescaling to be omitted.

*p5* ... *PMAX* -- Parameters whose meaning is determined by the particular GEN routine.

## Special Considerations

Function tables are arrays of floating-point values. You can create a simple sine wave using the line:

```
f 1 0 1024 10 1
```

This table uses *GEN10* to fill the table.

Historically, due to older platform constraints, Csound could only accept tables whose size was a power of two. This limitation has been removed in recent versions, and you can freely create tables of any size. However, to create a table whose size is not a power of two (or power of two plus one), you must specify the size as a negative number.

### Note

Not all opcodes accept tables whose size is not a power of two, since they may depend on this for internal optimization.

For arrays whose length is a power of 2, space allocation always provides for  $2^n$  points plus an additional *guard point*. The guard point value, used during interpolated lookup, can be automatically set to reflect the table's purpose: If *size* is an exact power of 2, the guard point will be a copy of the first point; this is appropriate for *interpolated wrap-around lookup* as in *oscili*, etc., and should even be used for non-interpolating *oscil* for safe consistency. If *size* is set to  $2^n + 1$ , the guard point value automatically extends the contour of table values; this is appropriate for single-scan functions such as *envplx*, *oscill*,

*oscill*i, etc.

The size of the table is used as a code to tell Csound how to fill this guard-point. If the size is exactly power-of-two, then the guard point contains a copy of the first point on the table. If the size is power-of-two plus one, Csound will extend the contour of the function stored in the table for one extra point.

Table space is allocated in primary memory, along with instrument data space. The maximum table number used to be 200. This has been changed to be limited by memory only. (Currently there is an internal soft limit of 300, this is automatically extended as required.)

An existing function table can be removed by an *f statement* containing a negative p1 and an appropriate action time. A function table can also be removed by the generation of another table with the same p1. Functions are not automatically erased at the end of a score section.

p2 action time is treated in the same way as in *i statements* with respect to sorting and modification by *t statements*. If an *f statement* and an *i statement* have the same p2, the sorter gives the *f statement* precedence so that the function table will be available during note initialization.

## Warning

The maximum number of p-fields accepted in the score is determined by PMAX (a compilation time variable). PMAX is currently set to 1000. This may discard values entered when using *GEN02*. To overcome this, use *GEN23* or *GEN28* to read the values from a file.

An *f 0 statement* (zero p1, positive p2) may be used to create an action time with no associated action. Such time markers are useful for padding out a score section (see *s statement*) and for letting Csound run from realtime events only (e.g. using only MIDI input without score events). The time given is the number of seconds Csound will run. If you want Csound to run for 10 hours, use:

f0 36000

The simplest way to fill a table (f1) with 0's is:

f1 0 xx 2 0

where xx = table size.

The simplest way to fill a table (f1) with \*any\* single value is:

f1 0 xx -7 yy xx yy

where xx = table size and yy = any single value

In both of the above examples, table size (p3) must be a power of 2 or power-of-2 plus 1.

## See also

*GEN ROUTINES*

## Credits

Updated August 2002 thanks to a note from Rasmus Ekman. There is no longer a hard limit of 200 function tables.

# i Statement (Instrument or Note Statement)

i — Makes an instrument active at a specific time and for a certain duration.

## Description

This statement calls for an instrument to be made active at a specific time and for a certain duration. The parameter field values are passed to that instrument prior to its initialization, and remain valid throughout its Performance.

## Syntax

i p1 p2 p3 p4 ...

## Initialization

p1 -- Instrument number, usually a non-negative integer. An optional fractional part can provide an additional tag for specifying ties between particular notes of consecutive clusters. A negative p1 (including tag) can be used to turn off a particular “held” note.

p2 -- Starting time in arbitrary units called beats.

p3 -- Duration time in beats (usually positive). A negative value will initiate a held note (see also *ihold*). A negative value can also be used for ‘always on’ instruments like reverberation. These notes are not terminated by *s statements*. A zero value will invoke an initialization pass without performance (see also *in-str*).

p4 ... -- Parameters whose significance is determined by the instrument.

## Performance

Beats are evaluated as seconds, unless there is a *t statement* in this score section or a *-t flag* in the command-line.

Starting or action times are relative to the beginning of a section ( see *s statement*), which is assigned time 0.

Note statements within a section may be placed in any order. Before being sent to an orchestra, unordered score statements must first be processed by Sorter, which will reorder them by ascending p2 value. Notes with the same p2 value will be ordered by ascending p1; if the same p1, then by ascending p3.

Notes may be stacked, i.e., a single instrument can perform any number of notes simultaneously. (The necessary copies of the instrument’s data space will be allocated dynamically by the orchestra loader.) Each note will normally turn off when its p3 duration has expired, or on receipt of a MIDI noteoff signal. An instrument can modify its own duration either by changing its p3 value during note initialization, or by prolonging itself through the action of a *linenr* or *xratim* unit.

An instrument may be turned on and left to perform indefinitely either by giving it a negative p3 or by including an *ihold* in its i-time code. If a held note is active, an *i statement with matching p1* will not cause a new allocation but will take over the data space of the held note. The new pfields (including p3) will now be in effect, and an i-time pass will be executed in which the units can either be newly initialized or allowed to continue as required for a tied note (see *tigoto*). A held note may be succeeded either

by another held note or by a note of finite duration. A held note will continue to perform across section endings (see *s statement*). It is halted only by *turnoff* or by an *i statement* with negative matching p1 or by an *e statement*.

It is possible to have multiple instances (usually, but not necessarily, notes of different pitches) of the same instrument, held simultaneously, via negative p3 values. The instrument can then be fed new parameters from the score. This is useful for avoiding long hard-coded *linsegs*, and can be accomplished by adding a decimal part to the instrument number.

For example, to hold three copies of instrument 10 in a simple chord:

```
i10.1    0    -1    7.00  
i10.2    0    -1    7.04  
i10.3    0    -1    7.07
```

Subsequent *i* statements can refer to the same sounding note instances, and if the instrument definition is done properly, the new p-fields can be used to alter the character of the notes in progress. For example, to bend the previous chord up an octave and release it:

```
i10.1    1    1    8.00  
i10.2    1    1    8.04  
i10.3    1    1    8.07
```

## Tip

When turning off notes, bear in mind that *i 1.1 == i 1.10* and *i 1.1 != i 1.01*. The maximum number of decimal places that can be used depends on the precision Csound was compiled with (See *Csound Double (64-bit) vs. Float (32-bit)*)

The instrument definition has to take this into account, however, especially if clicks are to be avoided (see the example below).

Note that the decimal instrument number notation cannot be used in conjunction with real-time MIDI. In this case, the instrument would be monophonic while a note was held.

Notes being tied to previous instances of the same instrument, should skip most initialization by means of *tigoto*, except for the values entered in score. For example, all table reading opcodes in the instrument, should usually be skipped, as they store their phase internally. If this is suddenly changed, there will be audible clicks in the output.

Note that many opcodes (such as *delay* and *reverb*) are prepared for optional initialization. To use this feature, the *tival opcode* is suitable. Therefore, they need not be hidden by a *tigoto* jump.

Beginning with Csound version 3.53, strings are recognized in p-fields for opcodes that accept them (*convolve*, *adsyn*, *diskin*, etc.). There may be only one string per score line.

You can also turnoff notes from the score by using a negative number for the instrument (p1). This is equivalent to using the *turnoff2* opcode. When a note is turned off from the score, it is allowed to release (if *xtratim* or opcodes with release section like *linenr* are used) and only notes with the same fractional part are turned off. Also, only the last instance of the instrument will be turned off, so there have to be as many negative instrument numbers as positive ones for all notes to be turned off.

---

```
i 1.1    1    300    8.00
```

```
i 1.2    1    300    8.04
i 1.3    1   -300    8.07
i 1.3    1   -300    8.09

; notice that p-fields after p2 will be ignored if
; instrument number is negative
i -1.1    3    1    4.00
i -1.2    4    51   4.04
i -1.3    5    1    4.07
i -1.3    6   10   4.09
```

## Special Considerations

The maximum instrument number used to be 200. This has been changed to be limited by memory only (currently there is an internal soft limit of 200; this is automatically extended as required).

## Examples

Here is an example of the i statement. It uses the file *i\_statement.csd* [examples/i\_statement.csd].

### Example 1083. Example of the i statement.

# m Statement (Mark Statement)

**m** — Sets a named mark in the score.

## Description

Sets a named mark in the score, which can be used by an *n statement*.

## Syntax

```
m p1
```

## Initialization

*p1* -- Name of mark.

## Performance

This can be helpful in setting up verse and chorus structure in the score. Names may contain letters and numerals.

For example, the following score:

```
m foo
i1 0 1
i1 1 1.5
i1 2.5 2
s
i1 0 10
s
n foo
e
```

Will be passed from the preprocessor to Csound as:

```
i1 0 1
i1 1 1.5
i1 2.5 2
s
i1 0 10
s
;this is named section repeated
i1 0 1
i1 1 1.5
i1 2.5 2
s
;end of named section
e
```

## Examples

Here is an example of the m statement. It uses the file *m.csd* [examples/m.csd].

### Example 1084. Example of the m statement.

# n Statement

n — Repeats a section.

## Description

Repeats a section from the referenced *m statement*.

## Syntax

```
n p1
```

## Initialization

*p1* -- Name of mark to repeat.

## Performance

This can be helpful in setting up verse and chorus structure in the score. Names may contain letters and numerals.

For example, the following score:

```
m foo
i1 0 1
i1 1 1.5
i1 2.5 2
s
i1 0 10
s
n foo
e
```

Will be passed from the preprocessor to Csound as:

```
i1 0 1
i1 1 1.5
i1 2.5 2
s
i1 0 10
s
;this is named section repeated
i1 0 1
i1 1 1.5
i1 2.5 2
s
;end of named section
e
```

## Examples

See the example for the *m statement*.

# q Statement

q statement — This statement may be used to quiet an instrument.

## Description

This statement may be used to quiet an instrument.

## Syntax

```
q p1  p2  p3
```

## Performance

*p1* -- Instrument number to mute/unmute.

*p2* -- Action time in beats.

*p3* -- determines whether the instrument is muted/unmuted. The value of 0 means the instrument is muted, other values mean it is unmuted.

Note that this does not affect instruments that are already running at time *p2*. It blocks any attempt to start one afterwards.

## Examples

Here is an example of the q statement. It uses the file *q.csd* [examples/q.csdl].

### Example 1085. Example of the q statement.

```
<CsoundSynthesizer>
<CsOptions>
; Select audio/midi flags here according to platform
-odac    ;;;realtime audio out
;-iadc   ;;;uncomment -iadc if RT audio input is needed too
; For Non-realtime output leave only the line below:
;-o q.wav -W ;;; for file output any platform
</CsOptions>
<CsInstruments>

# r Statement (Repeat Statement)

r — Starts a repeated section.

## Description

Starts a repeated section, which lasts until the next *s*, *r* or *e statement*.

## Syntax

**r p1 p2**

## Initialization

*p1* -- Number of times to repeat the section.

*p2* -- Macro(name) to advance with each repetition (optional).

## Performance

In order that the sections may be more flexible than simple editing, the macro named *p2* is given the value of 1 for the first time through the section, 2 for the second, and 3 for the third. This can be used to change p-field parameters, or ignored.

### Warning

Because of serious problems of interaction with macro expansion, sections must start and end in the same file, and not in a macro.

## Examples

Here is an example of the r statement. It uses the file *r.csd* [examples/r.csd].

### Example 1086. Example of the r statement.

Example written by Kevin Conder

# s Statement

**s** — Marks the end of a section.

## Description

The *s statement* marks the end of a section.

## Syntax

**s** [time]

## Initialization

The first p-field *time* is optional and if present determines the end time (length in beats) of the section. This time must be after the end of the last event in the section otherwise it will have no effect. This can be used to create a pause before the beginning of the next section or to allow "always on" instruments such as effects to play by themselves for some length of time.

## Performance

Sorting of the *i statement*, *f statement* and *a statement* by action time is done section by section.

Time warping for the *t statement* is done section by section.

All action times within a section are relative to its beginning. A section statement establishes a new relative time of 0, but has no other reinitializing effects (e.g. stored function tables are preserved across section boundaries).

A section is considered complete when all action times and finite durations have been satisfied (i.e., the "length" of a section is determined by the last occurring action or turn-off). A section can be extended by the use of an *f0 statement* or by supplying the optional *p1* value to the *s statement*.

A section ending automatically invokes a purge of inactive instrument and data spaces.

### Note

- Since score statements are processed section by section, the amount of memory required depends on the maximum number of score statements in a section. Memory allocation is dynamic, and the user will be informed as extra memory blocks are requested during score processing.
- For the end of the final section of a score, the *s statement* is optional; the *e statement* may be used instead.

## Examples

Here is an example of the *s statement*. It uses the file *s.csd* [examples/s.csd].

**Example 1087. Example of the s statement.**

```
<CsoundSynthesizer>
<CsOptions>

```

# t Statement (Tempo Statement)

**t** — Sets the tempo.

## Description

This statement sets the tempo and specifies the accelerations and decelerations for the current section. This is done by converting beats into seconds.

## Syntax

```
t p1 p2 p3 p4 ... (unlimited)
```

## Initialization

*p1* -- Must be zero.

*p2* -- Initial tempo on beats per minute.

*p3, p5, p7,...* -- Times in beats (in non-decreasing order).

*p4, p6, p8,...* -- Tempi for the referenced beat times.

## Performance

Time and Tempo-for-that-time are given as ordered couples that define points on a "tempo vs. time" graph. (The time-axis here is in beats so is not necessarily linear.) The beat-rate of a Section can be thought of as a movement from point to point on that graph: motion between two points of equal height signifies constant tempo, while motion between two points of unequal height will cause an accelerando or ritardando accordingly. The graph can contain discontinuities: two points given equal times but different tempi will cause an immediate tempo change.

Motion between different tempos over non-zero time is inverse linear. That is, an accelerando between two tempos M1 and M2 proceeds by linear interpolation of the single-beat durations from 60/M1 to 60/M2.

The first tempo given must be for beat 0.

A tempo, once assigned, will remain in effect from that time-point unless influenced by a succeeding tempo, i.e. the last specified tempo will be held to the end of the section.

A *t statement* applies only to the score section in which it appears. Only one *t statement* is meaningful in a section; it can be placed anywhere within that section. If a score section contains no *t statement*, then beats are interpreted as seconds (i.e. with an implicit *t 0 60* statement).

N.B. If the CSound command includes a *-t flag*, the interpreted tempo of all score *t statements* will be overridden by the command-line tempo.

## Examples

Here is an example of the t statement. It uses the file *t.csd* [examples/t.csd].

**Example 1088. Example of the t statement.**

# v Statement

v — Provides for locally variable time warping of score events.

## Description

The *v statement* provides for locally variable time warping of score events.

## Syntax

v p1

## Initialization

p1 -- Time warp factor (must be positive).

## Performance

The *v statement* takes effect with the following *i statement*, and remains in effect until the next *v statement*, *s statement*, or *e statement*.

## Examples

The value of p1 is used as a multiplier for the start times (p2) of subsequent *i statements*.

```
i1    0 1  ; note1  
v2  
i1    1 1  ; note2
```

In this example, the second note occurs two beats after the first note, and is twice as long.

Although the *v statement* is similar to the *t statement*, the *v statement* is local in operation. That is, *v* affects only the following notes, and its effect may be cancelled or changed by another *v statement*.

Carried values are unaffected by the *v statement* (see *Carry*).

```
i1    0 1  
v2  
i.    + .  
i.    . .
```

In this example, the *v statement* has no effect.

## Examples

Here is an example of the *v statement*. It uses the file *v.csd* [examples/v.csd].

**Example 1089. Example of the v statement.**

```
<CsoundSynthesizer>
<CsOptions>

# y Statement (or Seed Statement)

a — Set seed for random numbers.

## Description

Set seed for random numbers, either from p1 or, if omitted, the clock.

## Syntax

**y** [p1]

## Initialization

p1 -- An integer value between 0 and  $2^{32}$  used as a new seed for random numbers. If omitted, the system clock value will be used instead.

## Performance

The tilde symbol ~ can be used in an expression wherever a number is permissible to use. Each ~ will evaluate to a random value between zero (0) and one (1). If there is no y statement in the score, the pseudo-random generator will yield the same numbers in each performance. If a fixed seed is given, a different predictable series of pseudo-random numbers will be generated from this seed. If a y statement is used without p1, the system clock will be used as a seed, yielding a different series of pseudo-random numbers for each performance.

## Examples

Here is an example of the y statement. It uses the file *y\_statement.csd* [examples/y\_statement.csd].

### Example 1091. Example of the y statement.

```
<CsoundSynthesizer>
<CsOptions>

# { Statement

{ — Begins a non-sectional, nestable loop.

## Description

The { and } statements can be used to repeat a group of score statements. These loops do not constitute independent score sections and thus may repeat events within the same section. Multiple loops may overlap in time or be nested within each other.

## Syntax

{ p1 p2

## Initialization

p1 -- Number of times to repeat the loop.

p2 -- A macro name that is automatically defined at the beginning of the loop and whose value is advanced with each repetition (optional). The initial value is zero and the final value is (p1 - 1).

## Performance

The { statement is used in conjunction with the } statement to define repeating groups of other score events. A score loop begins with the { statement which defines the number of repetitions and a unique macro name that will contain the current loop counter. The body of a loop can contain any number of other events (including sectional breaks) and is terminated by a } statement on its own line. The } statement takes no parameters.

The use of the term "loop" here does not imply any sort of temporal succession to the loop iterations. In other words, the p2 values of the events inside of the loop are not automatically incremented by the length of the loop in each repetition. This is actually an advantage since it allows groups of simultaneous events to be easily defined as well. The loop macro can be used along with score expressions to increase the start times of events or to vary the events in any other way desired for each iteration. The macro is incremented by one for each repetition. Note that unlike the r statement, the value of the macro the first time through the loop is zero (0), not one (1). Therefore the final value is one less than the number of repetitions.

Score loops are a very powerful tool. While similar to the section repeat facility (the r statement), their chief advantage is that the score events in successive iterations of the loop are not separated by a section termination. Thus, it is possible to create multiple loops that overlap in time. Loops also can be nested within each other to a depth of 39 levels.

### Warning

Because of serious problems of interaction with macro expansion, loops must start and end in the same file, and not in a macro.

## Examples

Here are some examples of the { and } statements.

**Example 1092. Sequentially repeat a three-note phrase four times.**

```
{ 4 CNT  
i1 [ 0.00 + 0.75 * $CNT.] 0.2 220  
i1 [ 0.25 + 0.75 * $CNT.] . 440  
i1 [ 0.50 + 0.75 * $CNT.] . 880  
}
```

is interpreted as

```
i1 0.00 0.2 220  
i1 0.25 . 440  
i1 0.50 . 880  
  
i1 0.75 0.2 220  
i1 1.00 . 440  
i1 1.25 . 880  
  
i1 1.50 0.2 220  
i1 1.75 . 440  
i1 2.00 . 880  
  
i1 2.25 0.2 220  
i1 2.50 . 440  
i1 2.75 . 880
```

**Example 1093. Create a group of simultaneous harmonic partials.**

In this example, *p4* is assumed to be the frequency of the note event.

```
{ 8 PARTIAL  
i1 0 1 [100 * ($PARTIAL. + 1)]  
}
```

is interpreted as

```
i1 0 1 100  
i1 0 1 200  
i1 0 1 300  
i1 0 1 400  
i1 0 1 500  
i1 0 1 600  
i1 0 1 700  
i1 0 1 800
```

Here is a full example of the *{* and *}* statements. It uses the file *leftbrace.csd* [examples/leftbrace.csd].

# GEN Routines

GEN routines are used as data generators for function tables. When a function table is created using the *score statement* the GEN function is given as its fourth argument. A negative GEN number implies that the function is not rescaled, and maintains its original values.

## Sine/Cosine Generators:

- *GEN09* - Composite waveforms made up of weighted sums of simple sinusoids.

- *GEN10* - Composite waveforms made up of weighted sums of simple sinusoids.
- *GEN11* - Additive set of cosine partials.
- *GEN19* - Composite waveforms made up of weighted sums of simple sinusoids.
- *GEN30* - Generates harmonic partials by analyzing an existing table.
- *GEN33* - Generate composite waveforms by mixing simple sinusoids.
- *GEN34* - Generate composite waveforms by mixing simple sinusoids.

## Line/Exponential Segment Generators:

- *GEN05* - Constructs functions from segments of exponential curves.
- *GEN06* - Generates a function comprised of segments of cubic polynomials.
- *GEN07* - Constructs functions from segments of straight lines.
- *GEN08* - Generate a piecewise cubic spline curve.
- *GEN16* - Creates a table from a starting value to an ending value.
- *GEN25* - Construct functions from segments of exponential curves in breakpoint fashion.
- *GEN27* - Construct functions from segments of straight lines in breakpoint fashion.

## File Access GEN Routines:

- *GEN01* - Transfers data from a soundfile into a function table.
- *GEN23* - Reads numeric values from a text file.
- *GEN28* - Reads a text file which contains a time-tagged trajectory.
- *GEN49* - Transfers data from an MP3 soundfile into a function table.

## Numeric Value Access GEN Routines

- *GEN02* - Transfers data from immediate pfields into a function table.
- *GEN17* - Creates a step function from given x-y pairs.
- *GEN52* - Creates an interleaved multichannel table from the specified source tables, in the format expected by the *ftconv* opcode.

## Window Function GEN Routines

- *GEN20* - Generates functions of different windows.

## Random Function GEN Routines

- *GEN21* - Generates tables of different random distributions.
- *GEN40* - Generates a random distribution using a distribution histogram.
- *GEN41* - Generates a random list of numerical pairs.
- *GEN42* - Generates a random distribution of discrete ranges of values.
- *GEN43* - Loads a PVOCEX file containing a PV analysis.

## Waveshaping GEN Routines

- *GEN03* - Generates a stored function table by evaluating a polynomial.
- *GEN13* - Stores a polynomial whose coefficients derive from the Chebyshev polynomials of the first kind.
- *GEN14* - Stores a polynomial whose coefficients derive from Chebyshevs of the second kind.
- *GEN15* - Creates two tables of stored polynomial functions.

## Amplitude Scaling GEN Routines

- *GEN04* - Generates a normalizing function.
- *GEN12* - Generates the log of a modified Bessel function of the second kind.
- *GEN24* - Reads numeric values from another allocated function-table and rescales them.

## Mixing GEN Routines

- *GEN18* - Writes composite waveforms made up of pre-existing waveforms.
- *GEN31* - Mixes any waveform specified in an existing table.
- *GEN32* - Mixes any waveform, resampled with either FFT or linear interpolation.

## Pitch and Tuning GEN Routines

- *GEN51* - fills a table with a fully customized micro-tuning scale, in the manner of Csound opcodes *cpstun*, *cpstuni* and *cpstmid*.

## Named GEN Routines

Csound's GEN routines can be extended with GEN function plugins. There is currently a simple GEN plugin that provides exponential and hyperbolic tangent functions, and the sone function. There is also a generator called farey for the Farey sequence operations. These GEN functions are not called by number, but by name.

- "*tanh*" - fills a table from a hyperbolic tangent formula.
- "*exp*" - fills a table from an exponential formula.
- "*sone*" - fills a table from a sone function formula.
- "*farey*" - fills a table from a Farey sequence.
- "*wave*" - fills a table from a wavelet transform.
- "*padsynth*" - fills a table using the padsynth algorithm.

# GEN01

GEN01 — Transfers data from a soundfile into a function table.

## Description

This subroutine transfers data from a soundfile into a function table.

## Syntax

```
f# time size 1 filcod skiptime format channel
```

## Performance

*size* -- number of points in the table. Ordinarily a power of 2 or a power-of-2 plus 1 (see *f statement*); the maximum tablesize is 16777216 ( $2^{24}$ ) points. The allocation of table memory can be *deferred* by setting this parameter to 0; the size allocated is then the number of points in the file (probably not a power-of-2), and the table is not usable by normal oscillators, but it is usable by a *loscil* unit. The soundfile can also be mono or stereo.

*filcod* -- integer or character-string denoting the source soundfile name. An integer denotes the file *soundin.filcod*; a character-string (in double quotes, spaces permitted) gives the filename itself, optionally a full pathname. If not a full path, the file is sought first in the current directory, then in that given by the environment variable *SSDIR* (if defined) then by *SFDIR*. See also *soundin*.

*skiptime* -- begin reading at *skiptime* seconds into the file.

*channel* -- channel number to read in. 0 denotes read all channels.

*format* -- specifies the audio data-file format:

|                            |                           |
|----------------------------|---------------------------|
| 1 - 8-bit signed character | 4 - 16-bit short integers |
| 2 - 8-bit A-law bytes      | 5 - 32-bit long integers  |
| 3 - 8-bit U-law bytes      | 6 - 32-bit floats         |

If *format* = 0 the sample format is taken from the soundfile header, or by default from the CSound *-o* command-line flag.

## Note

- Reading stops at end-of-file or when the table is full. Table locations not filled will contain zeros.
- If p4 is positive, the table will be post-normalized (rescaled to a maximum absolute value of 1 after generation). A negative p4 will cause rescaling to be skipped.
- GEN01 also works with WAV and OGG and a dozen and more other sound formats; these file formats depend on libsndfile, see <http://www.mega-nerd.com/libsndfile/>

## Examples

Here is an example of the GEN01 routine. It uses the files *gen01.csd* [examples/gen01.csd] and several sound files.

### Example 1095. An example of the GEN01 routine.

```

f 3 0 0 1 "beats.ogg" 0 0 0 - deferred sound

## Credits

September 2003. Thanks goes to Dr. Richard Boulanger for pointing out the references to the AIFF file format.

# GEN02

GEN02 — Transfers data from immediate pfields into a function table.

## Description

This subroutine transfers data from immediate pfields into a function table.

## Syntax

```
f # time size 2 v1 v2 v3 ...
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or a power-of-2 plus 1 (see *f statement*). The maximum tablesize is 16777216 ( $2^{24}$ ) points.

*v1*, *v2*, *v3*, etc. -- values to be copied directly into the table space. The number of values is limited by the compile-time variable *PMAX*, which controls the maximum pfields (currently 1000). The values copied may include the table guard point; any table locations not filled will contain zeros.

### Note

If *p4* (the GEN routine number is positive, the table will be post-normalized (rescaled to a maximum absolute value of 1 after generation). A negative *p4* will cause rescaling to be skipped. You will usually want to use -2 with this GEN function, so that your values are not normalized.

## Examples

Here is an example of the GEN02 routine. It uses the files *gen02.csd* [examples/gen02.csd].

### Example 1096. Example of the GEN02 routine.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# GEN03

GEN03 — Generates a stored function table by evaluating a polynomial.

## Description

This subroutine generates a stored function table by evaluating a polynomial in x over a fixed interval and with specified coefficients.

## Syntax

```
f # time size 3 xval1 xval2 c0 c1 c2 ... cn
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or a power-of-2 plus 1.

*xval1*, *xval2* -- left and right values of the x interval over which the polynomial is defined (*xval1* < *xval2*). These will produce the 1st stored value and the (power-of-2 plus 1)th stored value respectively in the generated function table.

*c0, c1, c2, ..., cn* -- coefficients of the nth-order polynomial

$$C_0 + C_1 x + C_2 x^2 + \dots + C_n x^n$$

Coefficients may be positive or negative real numbers; a zero denotes a missing term in the polynomial. The coefficient list begins in p7, providing a current upper limit of 144 terms.

### Note

- The defined segment [fn(*xval1*), fn(*xval2*)] is evenly distributed. Thus a 512-point table over the interval [-1,1] will have its origin at location 257 (at the start of the 2nd half). Provided the extended guard point is requested, both fn(-1) and fn(1) will exist in the table.
- *GEN03* is useful in conjunction with *table* or *tablei* for audio waveshaping (sound modification by non-linear distortion). Coefficients to produce a particular formant from a sinusoidal lookup index of known amplitude can be determined at preprocessing time using algorithms such as Chebyshev formulae. See also *GEN13*.

## Examples

Here is an example of the GEN03 generator. It uses the file *gen03.csd* [examples/gen03.csd].

# GEN04

GEN04 — Generates a normalizing function.

## Description

This subroutine generates a normalizing function by examining the contents of an existing table.

## Syntax

```
f # time size 4 source# sourcemode
```

## Initialization

*size* -- number of points in the table. Should be power-of-2 plus 1. Must not exceed (except by 1) the size of the source table being examined; limited to just half that size if the sourcemode is of type offset (see below).

*source #* -- table number of stored function to be examined.

*sourcemode* -- a coded value, specifying how the source table is to be scanned to obtain the normalizing function. Zero indicates that the source is to be scanned from left to right. Non-zero indicates that the source has a bipolar structure; scanning will begin at the mid-point and progress outwards, looking at pairs of points equidistant from the center.

### Note

- The normalizing function derives from the progressive absolute maxima of the source table being scanned. The new table is created left-to-right, with stored values equal to  $1/(\text{absolute maximum so far scanned})$ . Stored values will thus begin with  $1/(\text{first value scanned})$ , then get progressively smaller as new maxima are encountered. For a source table which is normalized (values  $\leq 1$ ), the derived values will range from  $1/(\text{first value scanned})$  down to 1. If the first value scanned is zero, that inverse will be set to 1.
- The normalizing function from *GEN04* is not itself normalized.
- *GEN04* is useful for scaling a table-derived signal so that it has a consistent peak amplitude. A particular application occurs in waveshaping when the carrier (or indexing) signal is less than full amplitude.

## Examples

Here is a simple example of the GEN04 routine. It uses the files *gen04.csd* [examples/gen04.csd].

# GEN05

GEN05 — Constructs functions from segments of exponential curves.

## Description

Constructs functions from segments of exponential curves.

## Syntax

```
f # time size 5 a n1 b n2 c ...
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or power-of-2 plus 1 (see *f statement*).

*a, b, c, etc.* -- ordinate values, in odd-numbered pfields p5, p7, p9, . . . These must be nonzero and must be alike in sign.

*n1, n2, etc.* -- length of segment (no. of storage locations), in even-numbered pfields. Cannot be negative, but a zero is meaningful for specifying discontinuous waveforms. The sum  $n1 + n2 + \dots$  will normally equal *size* for fully specified functions. If the sum is smaller, the function locations not included will be set to zero; if the sum is greater, only the first *size* locations will be stored. Note that the values are rounded to integers before use.

### Note

- If p4 is positive, functions are post-normalized (rescaled to a maximum absolute value of 1 after generation). A negative p4 will cause rescaling to be skipped.
- Discrete-point linear interpolation implies an increase or decrease along a segment by equal differences between adjacent locations; exponential interpolation implies that the progression is by equal ratio. In both forms the interpolation from *a* to *b* is such as to assume that the value *b* will be attained in the *n + 1*th location. For discontinuous functions, and for the segment encompassing the end location, this value will not actually be reached, although it may eventually appear as a result of final scaling.

## Examples

Here is a simple example of the GEN05 routine. It uses the files *gen05.csd* [examples/gen05.csd].

### Example 1099. An example of the GEN05 routine.

# GEN06

GEN06 — Generates a function comprised of segments of cubic polynomials.

## Description

This subroutine will generate a function comprised of segments of cubic polynomials, spanning specified points just three at a time.

## Syntax

```
f #    time    size    6    a    n1    b    n2    c    n3    d ...
```

## Initialization

*size* -- number of points in the table. Must be a power off or power-of-2 plus 1 (see *f statement*).

*a, c, e, ...* -- local maxima or minima of successive segments, depending on the relation of these points to adjacent inflexions. May be either positive or negative.

*b, d, f, ...* -- ordinate values of points of inflexion at the ends of successive curved segments. May be positive or negative.

*n1, n2, n3 ...* -- number of stored values between specified points. Cannot be negative, but a zero is meaningful for specifying discontinuities. The sum  $n1 + n2 + \dots$  will normally equal *size* for fully specified functions. (for details, see *GEN05*).

### Note

*GEN06* constructs a stored function from segments of cubic polynomial functions. Segments link ordinate values in groups of 3: point of inflexion, maximum/minimum, point of inflexion. The first complete segment encompasses *b, c, d* and has length *n2 + n3*, the next encompasses *d, e, f* and has length *n4 + n5*, etc. The first segment (*a, b* with length *n1*) is partial with only one inflexion; the last segment may be partial too. Although the inflexion points *b, d, f, ...* each figure in two segments (to the left and right), the slope of the two segments remains independent at that common point (i.e. the 1st derivative will likely be discontinuous). When *a, c, e, ...* are alternately maximum and minimum, the inflexion joins will be relatively smooth; for successive maxima or successive minima the inflexions will be comb-like.

## Examples

Here is an example of the GEN06 routine. It uses the files *gen06.csd* [examples/gen06.csd].

## See Also

*GEN05*, *GEN06*, and *GEN08*

# GEN08

GEN08 — Generate a piecewise cubic spline curve.

## Description

This subroutine will generate a piecewise cubic spline curve, the smoothest possible through all specified points.

## Syntax

```
f # time size 8 a n1 b n2 c n3 d ...
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or power-of-2 plus 1 (see *f statement*).

*a, b, c, etc.* -- ordinate values of the function.

*n1, n2, n3 ...* -- length of each segment measured in stored values. May not be zero, but may be fractional. A particular segment may or may not actually store any values; stored values will be generated at integral points from the beginning of the function. The sum  $n1 + n2 + \dots$  will normally equal *size* for fully specified functions.

### Note

- *GEN08* constructs a stored table from segments of cubic polynomial functions. Each segment runs between two specified points but depends as well on their neighbors on each side. Neighboring segments will agree in both value and slope at their common point. (The common slope is that of a parabola through that point and its two neighbors). The slope at the two ends of the function is constrained to be zero (flat).
- *Hint:* to make a discontinuity in slope or value in the function as stored, arrange a series of points in the interval between two stored values; likewise for a non-zero boundary slope.

## Examples

Here is an example of the GEN08 routine. It uses the files *gen08.csd* [examples/gen08.csd].

GEN09 — Generate composite waveforms made up of weighted sums of simple sinusoids.

## Description

These subroutines generate composite waveforms made up of weighted sums of simple sinusoids. The specification of each contributing partial requires 3 p-fields using *GEN09*.

## Syntax

```
f # time size 9 pna stra phsa pnb strb phsb ...
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or power-of-2 plus 1 (see *f statement*).

*pna*, *pnb*, etc. -- partial no. (relative to a fundamental that would occupy *size* locations per cycle) of sinusoid a, sinusoid b, etc. Must be positive, but need not be a whole number, i.e., non-harmonic partials are permitted. Partials may be in any order.

*stra*, *strb*, etc. -- strength of partials *pna*, *pnb*, etc. These are relative strengths, since the composite waveform may be rescaled later. Negative values are permitted and imply a 180 degree phase shift.

*phsa*, *phsb*, etc. -- initial phase of partials *pna*, *pnb*, etc., expressed in degrees (0-360).

### Note

- These subroutines generate stored functions as sums of sinusoids of different frequencies. The two major restrictions on *GEN10* that the partials be harmonic and in phase do not apply to *GEN09* or *GEN19*.

In each case the composite wave, once drawn, is then rescaled to unity if p4 was positive. A negative p4 will cause rescaling to be skipped.

## Examples

Here is an example of the GEN09 routine. It uses the files *gen09.csd* [examples/gen09.csd].

### Example 1103. Example of the GEN09 routine.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

GEN10 — Generate composite waveforms made up of weighted sums of simple sinusoids.

## Description

These subroutines generate composite waveforms made up of weighted sums of simple sinusoids. The specification of each contributing partial requires 1 pfield using *GEN10*.

## Syntax

```
f # time size 10 str1 str2 str3 str4 ...
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or power-of-2 plus 1 (see *f statement*).

*str1, str2, str3, etc.* -- relative strengths of the fixed harmonic partial numbers 1,2,3, etc., beginning in p5. Partials not required should be given a strength of zero.

### Note

- These subroutines generate stored functions as sums of sinusoids of different frequencies. The two major restrictions on *GEN10* that the partials be harmonic and in phase do not apply to *GEN09* or *GEN19*.

In each case the composite wave, once drawn, is then rescaled to unity if p4 was positive. A negative p4 will cause rescaling to be skipped.

## Examples

Here is an example of the GEN10 routine. It uses the files *gen10.csd* [examples/gen10.csd].

# GEN11

GEN11 — Generates an additive set of cosine partials.

## Description

This subroutine generates an additive set of cosine partials, in the manner of Csound generators *buzz* and *gbuzz*.

## Syntax

```
f # time size nh [lh] [r]
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or power-of-2 plus 1 (see *f statement*).

*nh* -- number of harmonics requested. Must be positive.

*lh*(optional) -- lowest harmonic partial present. Can be positive, zero or negative. The set of partials can begin at any partial number and proceeds upwards; if *lh* is negative, all partials below zero will reflect in zero to produce positive partials without phase change (since cosine is an even function), and will add constructively to any positive partials in the set. The default value is 1

*r*(optional) -- multiplier in an amplitude coefficient series. This is a power series: if the *lh*th partial has a strength coefficient of *A* the (*lh* + *n*)th partial will have a coefficient of *A* \* *r*<sup>*n*</sup>, i.e. strength values trace an exponential curve. *r* may be positive, zero or negative, and is not restricted to integers. The default value is 1.

### Note

- This subroutine is a non-time-varying version of the CSound *buzz* and *gbuzz* generators, and is similarly useful as a complex sound source in subtractive synthesis. With *lh* and *r* present it parallels *gbuzz*; with both absent or equal to 1 it reduces to the simpler *buzz* (i.e. *nh* equal-strength harmonic partials beginning with the fundamental).
- Sampling the stored waveform with an oscillator is more efficient than using the dynamic *buzz* units. However, the spectral content is invariant and care is necessary, lest the higher partials exceed the Nyquist during sampling to produce fold-over.

## Examples

Here is an example of the GEN11 routine. It uses the files *gen11.csd* [*examples/gen01.csd*].

# GEN12

GEN12 — Generates the log of a modified Bessel function of the second kind.

## Description

This generates the log of a modified Bessel function of the second kind, order 0, suitable for use in amplitude-modulated FM.

## Syntax

```
f # time size 12 xint
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or a power-of-2 plus 1 (see *f statement*). The normal value is power-of-2 plus 1.

*xint* -- specifies the *x* interval [0 to *+xint*] over which the function is defined.

### Note

- This subroutine draws the natural log of a modified Bessel function of the second kind, order 0 (commonly written as  $I_0$ ), over the x-interval requested. The call should have rescaling inhibited.
- The function is useful as an amplitude scaling factor in cycle-synchronous amplitude-modulated FM. (See Palamin & Palamin, *J. Audio Eng. Soc.*, 36/9, Sept. 1988, pp.671-684.) The algorithm is interesting because it permits the normally symmetric FM spectrum to be made asymmetric around a frequency other than the carrier, and is thereby useful for formant positioning. By using a table lookup index of  $I(r - 1/r)$ , where  $I$  is the FM modulation index and  $r$  is an exponential parameter affecting partial strengths, the Palamin algorithm becomes relatively efficient, requiring only oscil's, table lookups, and a single *exp* call.

## Examples

Here is an example of the GEN12 generator. It uses the file *gen12.csd* [examples/gen12.csd].

# GEN13

GEN13 — Stores a polynomial whose coefficients derive from the Chebyshev polynomials of the first kind.

## Description

Uses Chebyshev coefficients to generate stored polynomial functions which, under waveshaping, can be used to split a sinusoid into harmonic partials having a pre-definable spectrum.

## Syntax

```
f # time size 13 xint xamp h0 h1 h2 ...
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or a power-of-2 plus 1 (see *f statement*). The normal value is power-of-2 plus 1.

*xint* -- provides the left and right values [-*xint*, +*xint*] of the x interval over which the polynomial is to be drawn. These subroutines both call *GEN03* to draw their functions; the p5 value here is therefore expanded to a negative-positive p5, p6 pair before *GEN03* is actually called. The normal value is 1.

*xamp* -- amplitude scaling factor of the sinusoid input that is expected to produce the following spectrum.

*h0*, *h1*, *h2*, etc. -- relative strength of partials 0 (DC), 1 (fundamental), 2 ... that will result when a sinusoid of amplitude

*xamp* \* int(*size*/2)/*xint*

is waveshaped using this function table. These values thus describe a frequency spectrum associated with a particular factor *xamp* of the input signal.

*GEN13* is the function generator normally employed in standard waveshaping. It stores a polynomial whose coefficients derive from the Chebyshev polynomials of the first kind, so that a driving sinusoid of strength *xamp* will exhibit the specified spectrum at output. Note that the evolution of this spectrum is generally not linear with varying *xamp*. However, it is bandlimited (the only partials to appear will be those specified at generation time); and the partials will tend to occur and to develop in ascending order (the lower partials dominating at low *xamp*, and the spectral richness increasing for higher values of *xamp*). A negative *hn* value implies a 180 degree phase shift of that partial; the requested full-amplitude spectrum will not be affected by this shift, although the evolution of several of its component partials may be. The pattern +,-,-,+,... for *h0,h1,h2...* will minimize the normalization problem for low *xamp* values (see above), but does not necessarily provide the smoothest pattern of evolution.

## Examples

Here is an example of the GEN13 generator. It uses the file *gen13.csd* [examples/gen13.csd].

# GEN14

GEN14 — Stores a polynomial whose coefficients derive from Chebyshevs of the second kind.

## Description

Uses Chebyshev coefficients to generate stored polynomial functions which, under waveshaping, can be used to split a sinusoid into harmonic partials having a pre-definable spectrum.

## Syntax

```
f # time size 14 xint xamp h0 h1 h2 ...
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or a power-of-2 plus 1 (see *f statement*). The normal value is power-of-2 plus 1.

*xint* -- provides the left and right values [-*xint*, +*xint*] of the x interval over which the polynomial is to be drawn. These subroutines both call *GEN03* to draw their functions; the p5 value here is therefore expanded to a negative-positive p5, p6 pair before *GEN03* is actually called. The normal value is 1.

*xamp* -- amplitude scaling factor of the sinusoid input that is expected to produce the following spectrum.

*h0*, *h1*, *h2*, etc. -- relative strength of partials 0 (DC), 1 (fundamental), 2 ... that will result when a sinusoid of amplitude

*xamp* \* int(*size*/2)/*xint*

is waveshaped using this function table. These values thus describe a frequency spectrum associated with a particular factor *xamp* of the input signal.

## Note

- *GEN13* is the function generator normally employed in standard waveshaping. It stores a polynomial whose coefficients derive from the Chebyshev polynomials of the first kind, so that a driving sinusoid of strength *xamp* will exhibit the specified spectrum at output. Note that the evolution of this spectrum is generally not linear with varying *xamp*. However, it is bandlimited (the only partials to appear will be those specified at generation time); and the partials will tend to occur and to develop in ascending order (the lower partials dominating at low *xamp*, and the spectral richness increasing for higher values of *xamp*). A negative *hn* value implies a 180 degree phase shift of that partial; the requested full-amplitude spectrum will not be affected by this shift, although the evolution of several of its component partials may be. The pattern +,-,+,-,... for *h0,h1,h2...* will minimize the normalization problem for low *xamp* values (see above), but does not necessarily provide the smoothest pattern of evolution.
- *GEN14* stores a polynomial whose coefficients derive from Chebyshevs of the second

kind.

## Examples

Here is an example of the GEN14 generator. It uses the file *gen14.csd* [examples/gen14.csd].

### Example 1108. Example of the GEN14 generator.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# GEN15

GEN15 — Creates two tables of stored polynomial functions.

## Description

This subroutine creates two tables of stored polynomial functions, suitable for use in phase quadrature operations.

## Syntax

```
f # time size 15 xint xamp h0 phs0 h1 phs1 h2 phs2 ...
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or a power-of-2 plus 1 (see *f statement*). The normal value is power-of-2 plus 1.

*xint* -- provides the left and right values [-*xint*, +*xint*] of the *x* interval over which the polynomial is to be drawn. This subroutine will eventually call *GEN03* to draw both functions; this p5 value is therefore expanded to a negative-positive p5, p6 pair before *GEN03* is actually called. The normal value is 1.

*xamp* -- amplitude scaling factor of the sinusoid input that is expected to produce the following spectrum.

*h0, h1, h2, ... hn* -- relative strength of partials 0 (DC), 1 (fundamental), 2 ... that will result when a sinusoid of amplitude

*xamp* \* int(*size*/2)/*xint*

is waveshaped using this function table. These values thus describe a frequency spectrum associated with a particular factor *xamp* of the input signal.

*phs0, phs1, ...* -- phase in degrees of desired harmonics *h0, h1, ...* when the two functions of *GEN15* are used with phase quadrature.

## Notes

*GEN15* creates two tables of equal size, labeled *f #* and *f # + 1*. Table # will contain a Chebyshev function of the first kind, drawn using *GEN13* with partial strengths *h0cos(phs0), h1cos(phs1), ...* Table #+1 will contain a Chebyshev function of the 2nd kind by calling *GEN14* with partials *h1sin(phs1), h2sin(phs2), ...* (note the harmonic displacement). The two tables can be used in conjunction in a waveshaping network that exploits phase quadrature.

Before version 5.16 there was a bug (pointed out by Menno Knevel and fixed by François Pinot) on the number of pfields transmitted to gen13 and gen14 by gen15. The consequence is that all the csd, or orc and sco files that used gen15 before this bug was fixed, are likely to sound different now.

# Examples

Here is an example of the GEN15 routine. It uses the files *gen15.cs*d [examples/gen15.cs].

# GEN16

GEN16 — Creates a table from a starting value to an ending value.

## Description

Creates a table from *beg* value to *end* value of *dur* steps.

## Syntax

```
f # time size 16 val1 dur1 type1 val2 [dur2 type2 val3 ... typeX valN]
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or a power-of-2 plus 1 (see *f statement*). The normal value is power-of-2 plus 1.

### Note

The end value is only reached when the table length is power-of-2 plus 1. (This length is crucial for use with the tab generator.)

*beg* -- starting value

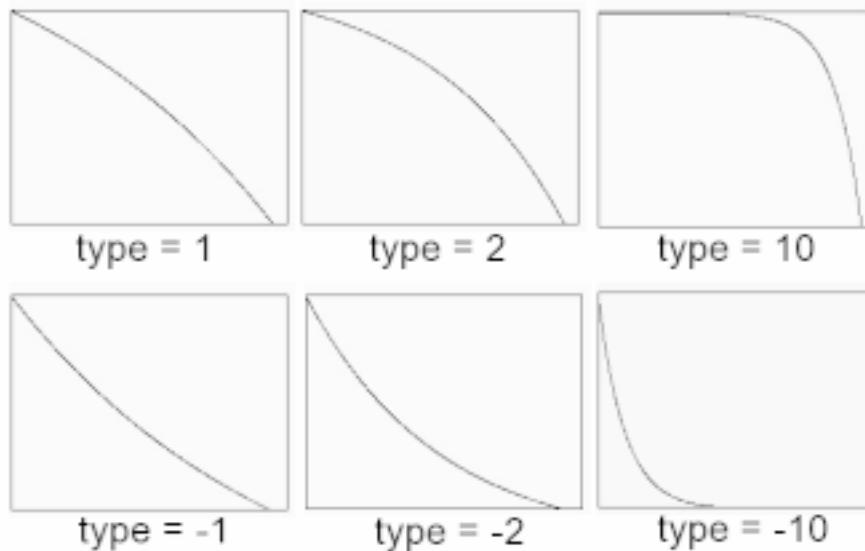

*dur* -- number of segments

*type* -- if 0, a straight line is produced. If non-zero, then *GEN16* creates the following curve, for *dur* steps:

$$\text{beg} + (\text{end} - \text{beg}) * (1 - \exp(-\text{i} * \text{type} / (\text{dur} - 1))) / (1 - \exp(\text{type}))$$

*end* -- value after *dur* segments

Here are some examples of the curves generated for different values of *type*:

Tables generated by GEN16 for different values of type.

### Note

If *type* > 0, there is a slowly rising (concave) or slowly decaying (convex) curve, while if *type* < 0, the curve is fast rising (convex) or fast decaying (concave). See also *transeg*.

# GEN17

GEN17 — Creates a step function from given x-y pairs.

## Description

This subroutine creates a step function from given x-y pairs.

## Syntax

```
f # time size 17 x1 a x2 b x3 c ...
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or a power-of-2 plus 1 (see *f statement*). The normal value is power-of-2 plus 1.

*x1, x2, x3*, etc. -- x-ordinate values, in ascending order, 0 first.

*a, b, c*, etc. -- y-values at those x-ordinates, held until the next x-ordinate.

### Note

This subroutine creates a step function of x-y pairs whose y-values are held to the right. The right-most y-value is then held to the end of the table. The function is useful for mapping one set of data values onto another, such as MIDI note numbers onto sampled sound ftable numbers ( see *loscil*).

## Examples

```
f 1 0 128 -17 0 1 12 2 24 3 36 4 48 5 60 6 72 7 84 8
```

This describes a step function with 8 successively increasing levels, each 12 locations wide except the last which extends its value to the end of the table. Rescaling is inhibited. Indexing into this table with a MIDI note-number would retrieve a different value every octave up to the eighth, above which the value returned would remain the same.

Here is a complete example of the GEN17 routine. It uses the files *gen17.csd* [examples/gen17.csd].

### Example 1111. An example of the GEN17 routine.

# GEN18

GEN18 — Writes composite waveforms made up of pre-existing waveforms.

## Description

Writes composite waveforms made up of pre-existing waveforms. Each contributing waveform requires 4 pfields and can overlap with other waveforms.

## Syntax

```
f # time size 18 fna ampa starta finisha fnb ampb startb finishb ...
```

## Initialization

*size* -- number of points in the table. Must be a power-of-2 (see f statement).

*fna, fnb, etc.* -- pre-existing table number to be written into the table.

*ampa, ampb, etc.* -- strength of wavefoms. These are relative strengths, since the composite waveform may be rescaled later. Negative values are permitted and imply a 180 degree phase shift.

*starta, startb, etc.* -- where to start writing the fn into the table.

*finisha, finishb, etc.* -- where to stop writing the fn into the table. The last available location is the power of two - 1.

## Examples

```
f 1 0 4096 10 1
f 2 0 1024 18 1 1 0 511 1 1 512 1023
```

f2 consists of two copies of f1 written in to locations 0-511 and 512-1023.

Here is an example of the GEN18 routine. It uses the files *gen18.cs* [examples/gen18.cs].

# GEN19

GEN19 — Generate composite waveforms made up of weighted sums of simple sinusoids.

## Description

These subroutines generate composite waveforms made up of weighted sums of simple sinusoids. The specification of each contributing partial requires 4 p-fields using *GEN19*.

## Syntax

```
f # time size 19 pna stra phsa dcoa pnb strb phsb dcob ...
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or power-of-2 plus 1 (see *f statement*).

*pna*, *pnb*, etc. -- partial no. (relative to a fundamental that would occupy *size* locations per cycle) of sinusoid a, sinusoid b, etc. Must be positive, but need not be a whole number, i.e., non-harmonic partials are permitted. Partials may be in any order.

*stra*, *strb*, etc. -- strength of partials *pna*, *pnb*, etc. These are relative strengths, since the composite waveform may be rescaled later. Negative values are permitted and imply a 180 degree phase shift.

*phsa*, *phsb*, etc. -- initial phase of partials *pna*, *pnb*, etc., expressed in degrees.

*dcoa*, *dcob*, etc. -- DC offset of partials *pna*, *pnb*, etc. This is applied *after* strength scaling, i.e. a value of 2 will lift a 2-strength sinusoid from range [-2,2] to range [0,4] (before later rescaling).

### Note

- These subroutines generate stored functions as sums of sinusoids of different frequencies. The two major restrictions on *GEN10* that the partials be harmonic and in phase do not apply to *GEN09* or *GEN19*.

In each case the composite wave, once drawn, is then rescaled to unity if p4 was positive. A negative p4 will cause rescaling to be skipped.

## Examples

Here is an example of the GEN19 routine. It uses the files *gen19.csd* [examples/gen19.csd].

# GEN20

GEN20 — Generates functions of different windows.

## Description

This subroutine generates functions of different windows. These windows are usually used for spectrum analysis or for grain envelopes.

## Syntax

```
f # time size 20 window max [opt]
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 (+ 1).

*window* -- Type of window to generate:

- 1 = Hamming
- 2 = Hanning
- 3 = Bartlett ( triangle)
- 4 = Blackman ( 3-term)
- 5 = Blackman - Harris ( 4-term)
- 6 = Gaussian
- 7 = Kaiser
- 8 = Rectangle
- 9 = Sync

*max* -- For negative p4 this will be the absolute value at window peak point. If p4 is positive or p4 is negative and p6 is missing the table will be post-rescaled to a maximum value of 1.

*opt* -- Optional argument required by the Gaussian window and the Kaiser window.

## Examples

```
f      1      0     1024    20      5
```

This creates a function which contains a 4 - term Blackman - Harris window with maximum value of 1.

```
f      1      0      1024     -20      2      456
```

This creates a function that contains a Hanning window with a maximum value of 456.

```
f      1      0      1024     -20      1
```

This creates a function that contains a Hamming window with a maximum value of 1.

```
f      1      0      1024     20      7      1      2
```

This creates a function that contains a Kaiser window with a maximum value of 1. The extra argument specifies how "open" the window is, for example a value of 0 results in a rectangular window and a value of 10 in a Hamming like window.

```
f      1      0      1024     20      6      1      2
```

This creates a function that contains a Gaussian window with a maximum value of 1. The extra argument specifies how broad the window is, as the standard deviation of the curve; in this example the s.d. is 2. The default value is 1.

For all diagrams, see *Window Functions*

Here is an example of the GEN20 routine. It uses the file *gen20.csd* [examples/gen20.csd].

Optional argument to Gaussian added in 5.10

# GEN21

GEN21 — Generates tables of different random distributions.

## Description

This generates tables of different random distributions. (See also *betarand*, *bexprnd*, *cauchy*, *exprand*, *gauss*, *linrand*, *pcauchy*, *poisson*, *trirand*, *unirand*, and *weibull*)

## Syntax

```
f # time size 21 type level [arg1  [arg2]]
```

## Initialization

*time* and *size* are the usual GEN function arguments. *level* defines the amplitude. Note that GEN21 is not self-normalizing as are most other GEN functions. *type* defines the distribution to be used as follow:

- 1 = Uniform (positive numbers only)
- 2 = Linear (positive numbers only)
- 3 = Triangular (positive and negative numbers)
- 4 = Exponential (positive numbers only)
- 5 = Biexponential (positive and negative numbers)
- 6 = Gaussian (positive and negative numbers)
- 7 = Cauchy (positive and negative numbers)
- 8 = Positive Cauchy (positive numbers only)
- 9 = Beta (positive numbers only)
- 10 = Weibull (positive numbers only)
- 11 = Poisson (positive numbers only)

Of all these cases only 9 (Beta) and 10 (Weibull) need extra arguments. Beta needs two arguments and Weibull one.

If *type* = 6, the random numbers in the ftable follow a normal distribution centered around 0.0 (*mu* = 0.0) with a variance (*sigma*) of *level* / 3.83. Thus more than 99.99% of the random values generated are in the range *-level* to *+level*. The default value for *level* is 1 (*sigma* = 0.261). If a mean value different of 0.0 is desired, this mean value has to be added to the generated numbers.

## Examples

```
f1 0 1024 21 1      ; Uniform (white noise)
f1 0 1024 21 6      ; Gaussian (mu=0.0, sigma=1/3.83=0.261)
f1 0 1024 21 6 5.745 ; Gaussian (mu=0.0, sigma=5.745/3.83=1.5)
f1 0 1024 21 9 1 1 2 ; Beta (note that level precedes arguments)
f1 0 1024 21 10 1 2 ; Weibull
```

All of the above additions were designed by the author between May and December 1994, under the supervision of Dr. Richard Boulanger.

Here is a complete example of the GEN21 routine. It uses the file *gen21.csd* [examples/gen21.csd].

# GEN23

GEN23 — Reads numeric values from a text file.

## Description

This subroutine reads numeric values from an external ASCII file.

## Syntax

```
f # time size -23 "filename.txt"
```

## Initialization

"filename.txt" -- numeric values contained in "filename.txt" (which indicates the complete pathname of the character file to be read), can be separated by spaces, tabs, newline characters or commas.

size -- number of points in the table. Must be a power of 2 , power of 2 + 1, or zero. If size = 0, table size is determined by the number of numeric values in *filename.txt*. (New in Csound version 3.57)

### Note

All characters following ';' , '#' (comment) or '<' (XML tag from version 6.04) are ignored until next line (numbers too).

## Examples

Here is an example of the GEN23 generator. It uses the file *gen23.csd* [examples/gen23.csd] and *spectrum.txt* [examples/spectrum.txt].

### Example 1116. Example of the GEN23 generator.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# GEN24

GEN24 — Reads numeric values from another allocated function-table and rescales them.

## Description

This subroutine reads numeric values from another allocated function-table and rescales them according to the max and min values given by the user.

## Syntax

```
f # time size -24 ftable min max
```

## Initialization

, *time*, *size* -- the usual GEN parameters. See f statement.

*ftable* -- ftable must be an already allocated table with the same size as this function.

*min*, *max* -- the rescaling range.

### Note

This GEN is useful, for example, to eliminate the starting offset in exponential segments allowing a real starting from zero.

## Examples

Here is an example of the GEN24 opcode. It uses the file *gen24.csd* [examples/gen24.csd].

### Example 1117. Example of the GEN24 generator.

# GEN25

GEN25 — Construct functions from segments of exponential curves in breakpoint fashion.

## Description

These subroutines are used to construct functions from segments of exponential curves in breakpoint fashion.

## Syntax

```
f # time size 25 x1 x2 y1 y2 x3 ...
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or power-of-2 plus 1 (see *f statement*).

*x1, x2, x3*, etc. -- locations in table at which to attain the following *y* value. Must be in increasing order. If the last value is less than *size*, then the rest will be set to zero. Should not be negative but can be zero.

*y1, y2, y3*, etc. -- Breakpoint values attained at the location specified by the preceding *x* value. These must be non-zero and must be alike in sign.

### Note

If *p4* is positive, functions are post-normalized (rescaled to a maximum absolute value of 1 after generation). A negative *p4* will cause rescaling to be skipped.

## Examples

Here is an example of the GEN25 generator. It uses the file *gen25.csd* [examples/gen25.csd].

# GEN28

GEN28 — Reads a text file which contains a time-tagged trajectory.

## Description

This function generator reads a text file which contains sets of three values representing the xy coordinates and a time-tag for when the signal should be placed at that location, allowing the user to define a time-tagged trajectory. The file format is in the form:

```
time1  X1    Y1  
time2  X2    Y2  
time3  X3    Y3
```

The configuration of the xy coordinates in space places the signal in the following way:

- a1 is -1, 1
- a2 is 1, 1
- a3 is -1, -1
- a4 is 1, -1

This assumes a loudspeaker set up as a1 is left front, a2 is right front, a3 is left back, a4 is right back. Values greater than 1 will result in sounds being attenuated as if in the distance. *GEN28* creates values to 10 milliseconds of resolution.

## Syntax

```
f # time size 28 ifilcod
```

## Initialization

*size* -- number of points in the table. Must be 0. *GEN28* takes 0 as the size and automatically allocates memory.

*ofilcod* -- character-string denoting the source file name. A character-string (in double quotes, spaces permitted) gives the filename itself, optionally a full pathname. If not a full path, the named file is sought in the current directory.

## Examples

```
f1 0 0 28 "move"
```

The file "move" should look like:

```
0    -1    1
1     1    1
2     4    4
2.1   -4   -4
3    10   -10
5   -40    0
```

Since *GEN28* creates values to 10 milliseconds of resolution, there will be 500 values created by interpolating X1 to X2 to X3 and so on, and Y1 to Y2 to Y3 and so on, over the appropriate number of values that are stored in the function table. The sound will begin in the left front, over 1 second it will move to the right front, over another second it moves further into the distance but still in the right front, then in just 1/10th of a second it moves to the left rear, a bit distant. Finally over the last .9 seconds the sound will move to the right rear, moderately distant, and it comes to rest between the two left channels (due west!), quite distant.

Here is an example of the *GEN28* routine. It uses the file *gen28.csd* [examples/gen28.csd].

# GEN30

GEN30 — Generates harmonic partials by analyzing an existing table.

## Description

Extracts a range of harmonic partials from an existing waveform.

## Syntax

```
f # time size 30 src minh maxh [ref_sr] [interp]
```

## Performance

*src* -- source ftable

*minh* -- lowest harmonic number

*maxh* -- highest harmonic number

*ref\_sr* (optional) -- *maxh* is scaled by (*sr* / *ref\_sr*). The default value of *ref\_sr* is *sr*. If *ref\_sr* is zero or negative, it is now ignored.

*interp* (optional) -- if non-zero, allows changing the amplitude of the lowest and highest harmonic partial depending on the fractional part of *minh* and *maxh*. For example, if *maxh* is 11.3 then the 12th harmonic partial is added with 0.3 amplitude. This parameter is zero by default.

*GEN30* does not support tables with an extended guard point (ie. table size = power of two + 1). Although such tables will work both for input and output, when reading source table(s), the guard point is ignored, and when writing the output table, guard point is simply copied from the first sample (table index = 0).

The reason of this limitation is that *GEN30* uses FFT, which requires power of two table size. *GEN32* allows using linear interpolation for resampling and phase shifting, which makes it possible to use any table size (however, for partials calculated with FFT, the power of two limitation still exists).

## Examples

Here is an example of the GEN30 routine. It uses the files *gen30.csd* [examples/gen30.csd].

### Example 1121. Example of the GEN30 routine.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# GEN31

GEN31 — Mixes any waveform specified in an existing table.

## Description

This routine is similar to GEN09, but allows mixing any waveform specified in an existing table.

## Syntax

```
f # time size 31 src pna stra phsa pnb strb phsb ...
```

## Performance

*src* -- source table number

*pna, pnb, ...* -- partial number, must be a positive integer

*stra, strb, ...* -- amplitude scale

*phsa, phsb, ...* -- start phase (0 to 1)

*GEN31* does not support tables with an extended guard point (ie. table size = power of two + 1). Although such tables will work both for input and output, when reading source table(s), the guard point is ignored, and when writing the output table, guard point is simply copied from the first sample (table index = 0).

The reason of this limitation is that *GEN31* uses FFT, which requires power of two table size. *GEN32* allows using linear interpolation for resampling and phase shifting, which makes it possible to use any table size (however, for partials calculated with FFT, the power of two limitation still exists).

# GEN32

GEN32 — Mixes any waveform, resampled with either FFT or linear interpolation.

## Description

This routine is similar to *GEN31*, but allows specifying source ftable for each partial. Tables can be resampled either with FFT, or linear interpolation.

## Syntax

```
f # time size 32 srca pna stra phsa srcb pnb strb phsb ...
```

## Performance

*srca, srcb* -- source table number. A negative value can be used to read the table with linear interpolation (by default, the source waveform is transposed and phase shifted using FFT); this is less accurate, but faster, and allows non-integer and negative partial numbers.

*pna, pnb, ...* -- partial number, must be a positive integer if source table number is positive (i.e. resample with FFT).

*stra, strb, ...* -- amplitude scale

*phsa, phsb, ...* -- start phase (0 to 1)

## Examples

Here is an example of the GEN32 routine. It uses the file *gen32.csd* [examples/gen32.csd].

# GEN33

GEN33 — Generate composite waveforms by mixing simple sinusoids.

## Description

These routines generate composite waveforms by mixing simple sinusoids, similarly to *GEN09*, but the parameters of the partials are specified in an already existing table, which makes it possible to calculate any number of partials in the orchestra.

The difference between *GEN33* and *GEN34* is that *GEN33* uses inverse FFT to generate output, while *GEN34* is based on the algorithm used in oscils opcode. *GEN33* allows integer partials only, and does not support power of two plus 1 table size, but may be significantly faster with a large number of partials. On the other hand, with *GEN34*, it is possible to use non-integer partial numbers and extended guard point, and this routine may be faster if there is only a small number of partials (note that *GEN34* is also several times faster than *GEN09*, although the latter may be more accurate).

## Syntax

```
f # time size 33 src nh scl [fmode]
```

## Initialization

*size* -- number of points in the table. Must be power of two and at least 4.

*src* -- source table number. This table contains the parameters of each partial in the following format:

stra, pna, phsa, strb, pnb, phsb, ...

the parameters are:

- stra, strb, etc.: relative strength of partials. The actual amplitude depends on the value of scl, or normalization (if enabled).
- pna, pnb, etc.: partial number, or frequency, depending on fmode (see below); zero and negative values are allowed, however, if the absolute value of the partial number exceeds (*size* / 2), the partial will not be rendered. With *GEN33*, partial number is rounded to the nearest integer.
- phsa, phsb, etc.: initial phase, in the range 0 to 1.

*nh* -- number of partials. Zero or negative values are allowed, and result in an empty table (silence). The actual number may be reduced if the source table (src) is too short, or some partials have too high frequency.

*scl* -- amplitude scale.

*fmode* (optional, default = 0) -- a non-zero value can be used to set frequency in Hz instead of partial numbers in the source table. The sample rate is assumed to be fmode if it is positive, or -(sr \* fmode) if

any negative value is specified.

## Examples

Here is an example of the GEN33 routine. It uses the file *gen33.csd* [examples/gen33.csd].

# GEN34

GEN34 — Generate composite waveforms by mixing simple sinusoids.

## Description

These routines generate composite waveforms by mixing simple sinusoids, similarly to *GEN09*, but the parameters of the partials are specified in an already existing table, which makes it possible to calculate any number of partials in the orchestra.

The difference between *GEN33* and *GEN34* is that *GEN33* uses inverse FFT to generate output, while *GEN34* is based on the algorithm used in oscils opcode. *GEN33* allows integer partials only, and does not support power of two plus 1 table size, but may be significantly faster with a large number of partials. On the other hand, with *GEN34*, it is possible to use non-integer partial numbers and extended guard point, and this routine may be faster if there is only a small number of partials (note that *GEN34* is also several times faster than *GEN09*, although the latter may be more accurate).

## Syntax

```
f # time size 34 src nh scl [fmode]
```

## Initialization

*size* -- number of points in the table. Must be power of two or a power of two plus 1.

*src* -- source table number. This table contains the parameters of each partial in the following format:

stra, pna, phsa, strb, pnb, phsb, ...

the parameters are:

- stra, strb, etc.: relative strength of partials. The actual amplitude depends on the value of scl, or normalization (if enabled).
- pna, pnb, etc.: partial number, or frequency, depending on fmode (see below); zero and negative values are allowed, however, if the absolute value of the partial number exceeds (size / 2), the partial will not be rendered.
- phsa, phsb, etc.: initial phase, in the range 0 to 1.

Table length (not including the guard point) should be at least 3 \* nh. If the table is too short, the number of partials (nh) is reduced to (table length) / 3, rounded towards zero.

*nh* -- number of partials. Zero or negative values are allowed, and result in an empty table (silence). The actual number may be reduced if the source table (src) is too short, or some partials have too high frequency.

*scl* -- amplitude scale.

*fmode* (optional, default = 0) -- a non-zero value can be used to set frequency in Hz instead of partial numbers in the source table. The sample rate is assumed to be fmode if it is positive, or -(sr \* fmode) if

any negative value is specified.

# GEN40

GEN40 — Generates a random distribution using a distribution histogram.

## Description

Generates a continuous random distribution function starting from the shape of a user-defined distribution histogram.

## Syntax

```
f # time size 40 shapetab
```

## Performance

The shape of histogram must be stored in a previously defined table, in fact shapetab argument must be filled with the number of such table.

Histogram shape can be generated with any other GEN routines. Since no interpolation is used when GEN40 processes the translation, it is suggested that the size of the table containing the histogram shape to be reasonably big, in order to obtain more precision (however after the processing the shaping-table can be destroyed in order to re-gain memory).

This subroutine is designed to be used together with cuserrnd opcode (see cuserrnd for more information).

## Examples

Here is an example of the GEN40 generator. It uses the file *gen40.csd* [examples/gen40.csd].

### Example 1125. Example of the GEN40 generator.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# GEN41

GEN41 — Generates a random list of numerical pairs.

## Description

Generates a discrete random distribution function by giving a list of numerical pairs.

## Syntax

```
f # time size -41 value1 prob1 value2 prob2 value3 prob3 ... valueN probN
```

## Performance

The first number of each pair is a value, and the second is the probability of that value to be chosen by a random algorithm. Even if any number can be assigned to the probability element of each pair, it is suggested to give it a percent value, in order to make it clearer for the user.

This subroutine is designed to be used together with duserrnd and *urd* opcodes (see duserrnd for more information).

## Examples

Here is an example of the GEN41 generator. It uses the file *gen41.csd* [examples/gen41.csd].

### Example 1126. Example of the GEN41 generator.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# GEN42

GEN42 — Generates a random distribution of discrete ranges of values.

## Description

Generates a random distribution function of discrete ranges of values by giving a list of groups of three numbers.

## Syntax

```
f # time size -42 min1 max1 prob1 min2 max2 prob2 min3 max3 prob3 ... minN maxN probN
```

## Performance

The first number of each group is the minimum value of the range, the second is the maximum value and the third is the probability of that an element belonging to that range of values can be chosen by a random algorithm. Probabilities for a range should be a fraction of 1, and the sum of the probabilities for all the ranges should total 1.0.

This subroutine is designed to be used together with duserrnd and *urd* opcodes (see duserrnd for more information). Since both duserrnd and *urd* do not use any interpolation, it is suggested to give a size reasonably big.

## Examples

Here is an example of the GEN42 generator. It uses the file *gen42.csd* [examples/gen42.csd].

### Example 1127. Example of the GEN42 generator.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# GEN43

GEN43 — Loads a PVOCEX file containing a PV analysis.

## Description

This subroutine loads a PVOCEX file containing the PV analysis (amp-freq) of a soundfile and calculates the average magnitudes of all analysis frames of one or all audio channels. It then creates a table with these magnitudes for each PV bin.

## Syntax

```
f # time size 43 filecod channel
```

## Initialisation

*size* -- number of points in the table, power-of-two or power-of-two plus 1. GEN 43 does not make any distinction between these two sizes, but it requires the table to be at least the fftsize/2. PV bins cover the positive spectrum from 0Hz (table index 0) to the Nyquist (table index fftsize/2+1) in equal-size frequency increments (of size sr/fftsize).

*filcod* -- a pvocecx file (which can be generated by pvanal).

*channel* -- audio channel number from which the magnitudes will be extracted; a 0 will average the magnitudes from all channels.

Reading stops at the end of the file.

### Note

if p4 is positive, the table will be post-normalised. A negative p4 will cause post-normalisation to be skipped.

## Examples

```
f1 0 512 43 "viola.pvx" 1  
f1 0 -1024 -43 "noiseprint.pvx" 0
```

This table can be used as a masking table for pvstencil and pvsmaska. The first example uses a 1024-point FFT phase vocoder analysis file from which the first channel is used. The second uses all channels of a 2048-point file, without post-normalisation. For noise reduction applications with pvstencil, it is easiest to skip table normalisation (negative GEN code).

# GEN49

GEN49 — Transfers data from an MP3 soundfile into a function table.

## Description

This subroutine transfers data from an MP3 soundfile into a function table.

## Syntax

```
f# time size 49 filcod skiptime format
```

## Performance

*size* -- number of points in the table. Ordinarily a power of 2 or a power-of-2 plus 1 (see *f statement*); the maximum tablesize is 16777216 ( $2^{24}$ ) points. The allocation of table memory can be *deferred* by setting this parameter to 0; the size allocated is then the number of points in the file (probably not a power-of-2), and the table is not usable by normal oscillators, but it is usable by a *loscil* unit. The soundfile can also be mono or stereo.

*filcod* -- integer or character-string denoting the source soundfile name. An integer denotes the file *soundin.filcod*; a character-string (in double quotes, spaces permitted) gives the filename itself, optionally a full pathname. If not a full path, the file is sought first in the current directory, then in that given by the environment variable *SSDIR* (if defined) then by *SFDIR*. See also *soundin*.

*skiptime* -- begin reading at *skiptime* seconds into the file.

*format* -- specifies the audio data-file format required:

|                 |                            |
|-----------------|----------------------------|
| 1 - Mono file   | 3 - First channel (left)   |
| 2 - Stereo file | 4 - Second channel (right) |

If *format* = 0 the sample format is taken from the soundfile header.

### Note

- Reading stops at end-of-file or when the table is full. Table locations not filled will contain zeros.
- If p4 is positive, the table will be post-normalized (rescaled to a maximum absolute value of 1 after generation). A negative p4 will cause rescaling to be skipped.

## Examples

# GEN51

GEN51 — This subroutine fills a table with a fully customized micro-tuning scale, in the manner of Csound opcodes *cpstun*, *cpstuni* and *cpstmid*.

## Description

This subroutine fills a table with a fully customized micro-tuning scale, in the manner of Csound opcodes *cpstun*, *cpstuni* et *cpstmid*.

## Syntax

```
f # time size -51 numgrades interval basefreq basekey tuningRatio1 tuningRatio2 .... tuningRationN
```

## Performance

The first four parameters (i.e. p5, p6, p7 and p8) define the following generation directives:

*p5 (numgrades)* -- the number of grades of the micro-tuning scale

*p6 (interval)* -- the frequency range covered before repeating the grade ratios, for example 2 for one octave, 1.5 for a fifth etcetera

*p7 (basefreq)* -- the base frequency of the scale in cps

*p8 (basekey)* -- the integer index of the scale to which to assign basefreq unmodified

The other parameters define the ratios of the scale:

*p9...pN (tuningRatio1...etc.)* -- the tuning ratios of the scale

For example, for a standard 12-grade scale with the base-frequency of 261 cps assigned to the key-number 60, the corresponding f-statement in the score to generate the table should be:

```
;      numgrades      basefreq      tuning-ratios (eq. temp) .....
;      interval        basekey
f1 0 64 -51      12          261          60          1    1.059463 1.12246 1.18920 ..etc...
```

After the gen has been processed, the table f1 is filled with 64 different frequency values. The 60th element is filled with the frequency value of 261, and all other elements (preceding and subsequents) of the table are filled according to the tuning ratios

Another example with a 24-grade scale with a base frequency of 440 assigned to the key-number 48, and a repetition interval of 1.5:

```
;      numgrades      basefreq      tuning-ratios .....
;      interval        basekey
f1 0 64 -51      24          1.5          440         48          1    1.01   1.02   1.03   ..etc...
```

## Examples

Here is an example of the GEN51 routine. It uses the files *gen51.csd* [examples/gen51.csd].

**Example 1129. An example of the GEN51 routine.**

# GEN52

GEN52 — Creates an interleaved multichannel table from the specified source tables, in the format expected by the *ftconv* opcode.

## Description

GEN52 creates an interleaved multichannel table from the specified source tables, in the format expected by the *ftconv* opcode. It can also be used to extract a channel from a multichannel table and store it in a normal mono table, copy tables with skipping some samples, adding delay, or store in reverse order, etc.

Three parameters must be given for each channel to be processed. *fsrc* declares the source f-table number. The parameter *offset* specifies an offset for the source file. If different to 0, the source file is not read from the beginning, but the *offset* number of values are skipped. The *offset* is used to determine the channel number to be read from interleaved f-tables, e.g. for channel 2, *offset* must be 1. It can also be used to set a read offset on the source table. This parameter gives absolute values, so if a skip of 20 sample frames for a 2 channel f-table is desired, *offset* must be set to 40. The *srcchnls* parameter is used to declare the number of channels in the source f-table. This parameter sets the skip size when reading the source f-table.

When more than one channel (*nchannels* > 1) is given, source f-tables are interleaved in the newly created table.

If the source f-table is finished before the destination f-table is full, the remaining values are set to 0.

## Syntax

```
f # time size 52 nchannels fsrcl offset1 srcchnls1 [fsrc2 offset2 srcchnls2 ... fsrCN offsetN srcchnlsN]
```

## Example

```
; source tables
f 1 0 16384 10 1
f 2 0 16384 10 0 1
; create 2 channel interleaved table
f 3 0 32768 -52 2 1 0 1 2 0 1
; extract first channel from table 3
f 4 0 16384 -52 1 3 0 2
; extract second channel from table 3
f 5 0 16384 -52 1 3 1 2
```

Here is a complete example of the GEN52 generator. It uses the file *gen52.csd* [examples/gen52.csd].

# GENtanh

"tanh" — Generate a table with values on the tanh function.

## Description

Creates an ftable with values of the tanh function.

## Syntax

```
f # time size "tanh" start end rescale
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or power-of-2 plus 1 (see *f statement*).

*start*, *end* -- first and last value to be stored; the GEN draws a curve that goes from start to end:  $\tanh(\text{start}) \dots \tanh(\text{end})$ . The points stored are uniformly spaced between these to the table size

*rescale* -- if not zero the table is not rescaled

## Examples

Here is a simple example of the GENtanh routine. It uses the file *gentanh.csd* [examples/gentanh.csd].

### Example 1131. Example of the GENtanh routine.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# GENexp

"exp" — Generate a table with values on the exp function.

## Description

Creates an ftable with values of the exp function.

## Syntax

```
f # time size "exp" start end rescale
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or power-of-2 plus 1 (see *f statement*).

*start*, *end* -- first and last value to be stored; the GEN draws a curve that goes from start to end:  $\exp(\text{start}) \dots \exp(\text{end})$ . The points stored are uniformly spaced between these to the table size

*rescale* -- if not zero the table is not rescaled

## Examples

Here is a simple example of the GENexp routine. It uses the file *genexp.csd* [examples/genexp.csd].

### Example 1132. Example of the GENexp routine.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# GENsone

"sone" — Generate a table with values of the sone function.

## Description

Creates an ftable with values of the sone function for equal power.

## Syntax

```
f # time size "sone" start end equalpoint rescale
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or power-of-2 plus 1 (see *f statement*).

*start, end* -- first and last value to be stored. The points stored are uniformly spaced between these to the table size.

*equalpoint* -- the point on the curve when the input and output values are equal.

*rescale* -- if not zero the table is not rescaled

The table is filled with the function  $x * \text{POWER}(x/\text{eqlp}, \text{FL}(33.0)/\text{FL}(78.0))$  for  $x$  between the start and end points. This is the Sone loudness curve.

## Examples

# GENfarey

"farey" — Fills a table with the Farey Sequence  $F_n$  of the integer n.

## Description

A Farey Sequence  $F_n$  of order n is a list of fractions in their lowest terms between 0 and 1 and in ascending order. Their denominators do not exceed n. This means a fraction  $a/b$  belongs to  $F_n$  if  $0 \leq a \leq b \leq n$ . The numerator and denominator of each fraction are always coprime. 0 and 1 are included in  $F_n$  as the fractions  $0/1$  and  $1/1$ . For example  $F_5 = \{0/1, 1/5, 1/4, 1/3, 2/5, 1/2, 3/5, 2/3, 3/4, 4/5, 1/1\}$  Some properties of the Farey Sequence:

- If  $a/b$  and  $c/d$  are two successive terms of  $F_n$ , then  $bc - ad = 1$ .
- If  $a/b, c/d, e/f$  are three successive terms of  $F_n$ , then:  $c/d = (a+e) / (b+f)$ . In this case  $c/d$  is called the mediant fraction between  $a/b$  and  $e/f$ .
- If  $n > 1$ , then no two successive terms of  $F_n$  have the same denominator.

The length of any Farey Sequence  $F_n$  is determined by  $|F_n| = 1 + \sum_{m=1}^n \phi(m)$  where  $\phi(m)$  is Euler's totient function, which gives the number of integers  $\leq m$  that are coprime to m.

Some values for the length of  $F_n$  given n:

| <b>n</b> | <b>F<sub>n</sub></b> |
|----------|----------------------|
| 1        | 2                    |
| 2        | 3                    |
| 3        | 5                    |
| 4        | 7                    |
| 5        | 11                   |
| 6        | 13                   |
| 7        | 19                   |
| 8        | 23                   |
| 9        | 29                   |
| 10       | 33                   |
| 11       | 43                   |
| 12       | 47                   |
| 13       | 59                   |
| 14       | 65                   |
| 15       | 73                   |
| 16       | 81                   |
| 17       | 97                   |
| 18       | 103                  |
| 19       | 121                  |
| 20       | 129                  |

## Syntax

```
f # time size "farey" fareynum mode
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or power-of-2 plus 1 (see *f statement*).

*fareynum* -- the integer  $n$  for generating Farey Sequence  $F_n$

*mode* -- integer to trigger a specific output to be written into the table:

- 0 -- outputs floating point numbers representing the elements of  $F_n$ .
- 1 -- outputs delta values of successive elements of  $F_n$ , useful for generating note durations for example.
- 2 -- outputs only the denominators of the integer ratios, useful for indexing other tables or instruments for example.
- 3 -- same as mode 2 but with normalised output.
- 4 -- same as mode 0 but with 1 added to each number, useful for generating tables for tuning opcodes, for example *cps2pch*.

## Examples

```
f1 0 -23 "farey" 8 0
```

This generates Farey Sequence  $F_8$ . The table contains all 23 elements of  $F_8$  as floating point numbers.

```
f1 0 -18 "farey" 7 1
```

This generates Farey Sequence  $F_7$ . The table contains 18 delta values of  $F_7$ , i.e. the difference between  $r_{i+1} - r_i$ , where  $r$  is the  $i$ th element of  $F_n$ .

```
f1 0 -43 "farey" 11 2
```

This generates Farey Sequence  $F_{11}$ . The table contains the denominators of all 43 fractions in  $F_{11}$ .

```
f1 0 -43 "farey" 11 3
```

This generates Farey Sequence  $F_{11}$ . The table contains the denominators of all 43 fractions in  $F_{11}$ , each of those divided by 11, i.e. normalised.

```
f1 0 -18 "farey" 7 4
```

This generates Farey Sequence  $F_7$ . The table contains all fractions of  $F_7$ , same as mode 0, but this time '1' is added to each table element.

### Example 1134. A simple example of the GENfarey routine.

# GENwave

"wave" — Generates a compactly supported wavelet function.

## Description

Creates a compactly supported wavelet, scaling function or wavelet packet. The output function is obtained by deconvolution of corresponding mirror filter impulse response. This procedure is applied in an iterative fashion.

The filter bank used in classic discrete wavelet transform grows only towards low frequencies. Meanwhile wavelet packet transform introduces any possible direction of tree's growth. The sequence of mirror filters used in deconvolution is determined by binary form of seq value. "0" corresponds to low-pass filter and "1" to high-pass.

The number of iteration steps is determined by filter's length and size of function table. I.e. for filter length 8 and table size 256 there are  $\log_2(256/8) = 5$  iterations available.

## Syntax

```
f # time size "wave" fnsf seq rescale
```

## Initialization

*size* -- number of points in the table. Must be a power of 2 or power-of-2 plus 1 (see *f statement*).

*fnsf* -- pre-existing table with scaling function coefficients.

*seq* -- non-negative integer number which corresponds to sequence of low-pass and high-pass mirror filters during deconvolution procedure.

*rescale* -- if not zero the table is not rescaled

## Examples

Here is an example of the GENwave routine. It uses the file *genwave.csd* [examples/genwave.csd].

### Example 1136. Example of the GENwave routine.

# GENpadsynth

"padsynth" — Generate a sample table using the padsynth algorithm.

## Description

Creates an ftable for use in an oscillator with values created by the padsynth algorithm.

## DRAFT Syntax

```
f # time size "padsynth" fundamentalFrq  
partialBW partial_Scale harmonicStretch hamp11, hamp12, ...
```

## DRAFT Initialization

*size* -- number of points in the table. Must be a power of 2 or power-of-2 plus 1 (see *f statement*).

*fundamentalFrq* -- fundamental frequency for the generated table.

*partialBW* -- bandwidth of each partial in cents.

*partialScale* -- ratio that bandwidth increases with harmonic number.

*harmonicStretchScale* -- ratio of stretch of three overtones.

*hamp1, hamp2, ...* -- relative amplitudes of the partials

The table is filled with a sample that can be used in an oscillator

## Examples

Here is an example of the GENpadsynth routine. It uses the files *padsynth\_gen.csd* [examples/pad-synth\_gen.csd].

### Example 1137. An example of the GENpadsynth routine.

# **Experimental Orchestra Opcodes and GEN Routines**

## **Experimental Orchestra Opcodes**

The following opcodes require a nVidia GPU to be present. They are distributed with the hope that they may be useful, and to encourage the use of parallelism in audio processing. Some of the new opcodes perform the same process as conventional existing ones but some are new.

## cudanal

cudanal — Generate an fsig from a mono audio source ain, using phase vocoder overlap-add analysis and GPU hardware.

## Description

Generate an fsig from a mono audio source ain, using phase vocoder overlap-add analysis and GPU hardware.

## Syntax

```
fsig cudanal ain, ifftsize, ioverlap, iwinsize, iwintype [, iformat] [, iinit]
```

## Initialization

*ifftsize* -- The FFT size in samples. Need not be a power of two (though these are especially efficient), but must be even. Odd numbers are rounded up internally. *ifftsize* determines the number of analysis bins in *fsig*, as *ifftsize*/2 + 1. For example, where *ifftsize* = 1024, *fsig* will contain 513 analysis bins, ordered linearly from the fundamental to Nyquist. The fundamental of analysis (which in principle gives the lowest resolvable frequency) is determined as *sr/ifftsize*. Thus, for the example just given and assuming *sr* = 44100, the fundamental of analysis is 43.07Hz. In practice, due to the phase-preserving nature of the phase vocoder, the frequency of any bin can deviate bilaterally, so that DC components are recorded. Given a strongly pitched signal, frequencies in adjacent bins can bunch very closely together, around partials in the source, and the lowest bins may even have negative frequencies.

As a rule, the only reason to use a non power-of-two value for *ifftsize* would be to match the known fundamental frequency of a strongly pitched source. Values with many small factors can be almost as efficient as power-of-two sizes; for example: 384, for a source pitched at around low A=110Hz.

*overlap* -- The distance in samples (“hop size”) between overlapping analysis frames. As a rule, this needs to be at least *ifftsize*/4, e.g. 256 for the example above. *overlap* determines the underlying analysis rate, as *sr/overlap*. *overlap* does not require to be a simple factor of *ifftsize*; for example a value of 160 would be legal. The choice of *overlap* may be dictated by the degree of pitch modification applied to the *fsig*, if any. As a rule of thumb, the more extreme the pitch shift, the higher the analysis rate needs to be, and hence the smaller the value for *overlap*. A higher analysis rate can also be advantageous with broadband transient sounds, such as drums (where a small analysis window gives less smearing, but more frequency-related errors).

Note that it is possible, and reasonable, to have distinct fsigs in an orchestra (even in the same instrument), running at different analysis rates. Interactions between such fsigs is currently unsupported, and the fsig assignment opcode does not allow copying between fsigs with different properties, even if the only difference is in *overlap*. However, this is not a closed issue, as it is possible in theory to achieve crude rate conversion (especially with regard to in-memory analysis files) in ways analogous to time-domain techniques.

*iwinsize* -- The size in samples of the analysis window filter (as set by *iwintype*). This must be at least *ifftsize*, and can usefully be larger. Though other proportions are permitted, it is recommended that *iwinsize* always be an integral multiple of *ifftsize*, e.g. 2048 for the example above. Internally, the analysis window (Hamming, von Hann) is multiplied by a sinc function, so that amplitudes are zero at the boundaries between frames. The larger analysis window size has been found to be especially important for oscillator bank resynthesis (e.g. using *cudadsyn*), as it has the effect of increasing the frequency resolution of the analysis, and hence the accuracy of the resynthesis. As noted above, *iwinsize* determines the over-

all latency of the analysis/resynthesis system. In many cases, and especially in the absence of pitch modifications, it will be found that setting *iwinsize*=*ifftsize* works very well, and offers the lowest latency.

*iwintype* -- The shape of the analysis window. Currently only two choices are implemented:

- 0 = Hamming window
- 1 = von Hann window

Both are also supported by the PVOC-EX file format. The window type is stored as an internal attribute of the fsig, together with the other parameters (see *pvsinfo*). Other types may be implemented later on (e.g. the Kaiser window, also supported by PVOC-EX), though an obvious alternative is to enable windows to be defined via a function table. The main issue here is the constraint of f-tables to power-of-two sizes, so this method does not offer a complete solution. Most users will find the Hamming window meets all normal needs, and can be regarded as the default choice.

*iformat* -- (optional) The analysis format. Currently only one format is implemented by this opcode:

- 0 = amplitude + frequency

This is the classic phase vocoder format; easy to process, and a natural format for oscillator-bank resynthesis. It would be very easy (tempting, one might say) to treat an fsig frame not purely as a phase vocoder frame but as a generic additive synthesis frame. It is indeed possible to use an fsig this way, but it is important to bear in mind that the two are not, strictly speaking, directly equivalent.

Other important formats (supported by PVOC-EX) are:

- 1 = amplitude + phase
- 2 = complex (real + imaginary)

*iformat* is provided in case it proves useful later to add support for these other formats. Formats 0 and 1 are very closely related (as the phase is “wrapped” in both cases - it is a trivial matter to convert from one to the other), but the complex format might warrant a second explicit signal type (a “csig”) specifically for convolution-based processes, and other processes where the full complement of arithmetic operators may be useful.

*iinit* -- (optional) Skip reinitialization. This is not currently implemented for any of these opcodes, and it remains to be seen if it is even practical.

## Warning

It is unsafe to use the same f-variable for both input and output of cuda opcodes. Using the same one might lead to undefined behavior on some opcodes. Use a different one on the left and right sides of the opcode.

## Examples

Here is an example of the cudanal opcode. It uses the file *cudanal.csd* [examples/cudanal.csd].

### Example 1138. Example of the cudanal opcode.

# **Deprecated Orchestra Opcodes and GEN Routines**

## **Deprecated Orchestra Opcodes**

The following opcodes are deprecated. They are still distributed with Csound for backward compatibility. The new opcodes which are to be used in place of the deprecated ones are indicated within each of the following entries.

## abetarand

abetarand — Deprecated.

### Description

Deprecated as of version 3.49. Use the *betarand* opcode instead.

## abexprnd

abexprnd — Deprecated.

### Description

Deprecated as of version 3.49. Use the *bexprnd* opcode instead.

## acauchy

acauchy — Deprecated.

### Description

Deprecated as of version 3.49. Use the *cauchy* opcode instead.

## aexprand

aexprand — Deprecated.

### Description

Deprecated as of version 3.49. Use the *exprand* opcode instead.

## agauss

agauss — Deprecated.

### Description

Deprecated as of version 3.49. Use the *gauss* opcode instead.

# agogobel

agogobel — Deprecated.

## Description

New in version 3.47

Deprecated as of version 3.52. Use the *gogobel* opcode instead.

## alinrand

alinrand — Deprecated.

### Description

Deprecated as of version 3.49. Use the *linrand* opcode instead.

## apcauchy

apcauchy — Deprecated.

### Description

Deprecated as of version 3.49. Use the *pcauchy* opcode instead.

# apoisson

apoisson — Deprecated.

## Description

Deprecated as of version 3.49. Use the *poisson* opcode instead.

## apow

apow — Deprecated.

### Description

Deprecated as of version 3.48. Use the *pow* opcode instead.

# array

array — Deprecated.

## Description

Generate a vector (one-dimensional k-rate array) with initial values.

## Syntax

```
karray[] array ival1, ival2,....ivaln
```

## Initialization

*ival1,...ivaln* -- values to place in the vector.

## Examples

Here is an example of the array opcode. It uses the file *array.csd* [examples/array.csd].

### Example 1141. Example of the array opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

```
<CsoundSynthesizer>
<CsOptions>

## attrirand

attrirand — Deprecated.

### Description

Deprecated as of version 3.49. Use the *trirand* opcode instead.

## aunirand

aunirand — Deprecated.

### Description

Deprecated as of version 3.49. Use the *unirand* opcode instead.

## aweibull

aweibull — Deprecated.

### Description

Deprecated as of version 3.49. Use the *weibull* opcode instead.

## bformdec

bformdec — Deprecated. Decodes an ambisonic B format signal.

## Description

Decodes an ambisonic B format signal into loudspeaker specific signals. Note that this opcode is deprecated as it is inaccurate, and is replaced by the much better opcode *bformdec1* which replicates all the important features.

## Syntax

```
a01, ao2 bformdec isetup, aw, ax, ay, az [, ar, as, at, au, av \
[, abk, al, am, an, ao, ap, aq]]  
  
a01, ao2, ao3, ao4 bformdec isetup, aw, ax, ay, az [, ar, as, at, \
au, av [, abk, al, am, an, ao, ap, aq]]  
  
a01, ao2, ao3, ao4, ao5 bformdec isetup, aw, ax, ay, az [, ar, as, \
at, au, av [, abk, al, am, an, ao, ap, aq]]  
  
a01, ao2, ao3, ao4, ao5, ao6, ao7, ao8 bformdec isetup, aw, ax, ay, az \
[, ar, as, at, au, av [, abk, al, am, an, ao, ap, aq]]]
```

## Initialization

*isetup* -- loudspeaker setup. There are five supported setups: 1 denotes stereo setup. There must be two output cells with loudspeaker positions assumed to be (330/0, 30/0).

2 denotes quad setup. There must be four output cells. Loudspeaker positions assumed to be (45°/0), (135°/0), (225/0), (315/0).

3 is a 5.1 surround setup. There must be five output cells. LFE channel is not supported. Loudspeaker positions assumed to be (330/0), (30/0), (0/0), (250/0), (110/0).

4 denotes eight loudspeaker circle setup. There must be eight output cells. Loudspeaker positions assumed to be (22.5/0), (67.5/0), (112.5/0), (157.5/0), (202.5/0), (247.5/0), (292.5/0), (337.5/0).

5 means an eight loudspeaker cubic setup. There must be eight output cells. Loudspeaker positions assumed to be (45/0), (45/30), (135/0), (135/30), (225/0), (225/30), (315/0), (315/30).

## Performance

*aw, ax, ay, ...* -- input signal in the B format.

*ao1 .. ao8* -- loudspeaker specific output signals.

## Example

Here is an example of the bformdec opcode. It uses the file *bformenc.csd* [examples/bformenc.csd].

### Example 1142. Example of the bformdec opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# bformenc

bformenc — Deprecated. Codes a signal into the ambisonic B format.

## Description

Codes a signal into the ambisonic B format. Note that this opcode is deprecated as it is inaccurate, and is replaced by the much better opcode *bformenc1* which replicates all the important features; also note that the gain arguments are not available in *bformenc1*.

## Syntax

```
aw, ax, ay, az bformenc asig, kalpha, kbeta, kord0, kord1  
  
aw, ax, ay, az, ar, as, at, au, av bformenc asig, kalpha, kbeta, \  
kord0, kord1 , kord2  
  
aw, ax, ay, az, ar, as, at, au, av, ak, al, am, an, ao, ap, aq bformenc \  
asig, kalpha, kbeta, kord0, kord1, kord2, kord3
```

## Performance

*aw, ax, ay, ...* -- output cells of the B format.

*asig* -- input signal.

*kalpha* -- azimuth angle in degrees (clockwise).

*kbeta* -- altitude angle in degrees.

*kord0* -- linear gain of the zero order B format.

*kord1* -- linear gain of the first order B format.

*kord2* -- linear gain of the second order B format.

*kord3* -- linear gain of the third order B format.

## Example

Here is an example of the bformenc opcode. It uses the file *bformenc.csd* [examples/bformenc.csd].

### Example 1143. Example of the bformenc opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# clock

clock — Deprecated.

## Description

Deprecated. Use the *rtclock* opcode instead.

# hrtfer

hrtfer — Creates 3D audio for two speakers.

## Description

Output is binaural (headphone) 3D audio.

### Note

This opcode is deprecated; use hrtfstat or similar opcode instead

## Syntax

```
aleft, aright hrtfer asig, kaz, kelev, "HRTFcompact"
```

## Initialization

*kAz* -- azimuth value in degrees. Positive values represent position on the right, negative values are positions on the left.

*kElev* -- elevation value in degrees. Positive values represent position above horizontal, negative values are positions under horizontal.

At present, the only file which can be used with *hrtfer* is *HRTFcompact* [examples/HRTFcompact]. It must be passed to the opcode as the last argument within quotes as shown above.

HRTFcompact may also be obtained via anonymous ftp from:  
<ftp://ftp.cs.bath.ac.uk/pub/dream/utilities/Analysis/HRTFcompact>

## Performance

These unit generators place a mono input signal in a virtual 3D space around the listener by convolving the input with the appropriate HRTF data specified by the opcode's azimuth and elevation values. *hrtfer* allows these values to be k-values, allowing for dynamic spatialization. *hrtfer* can only place the input at the requested position because the HRTF is loaded in at i-time (remember that currently, CSound has a limit of 20 files it can hold in memory, otherwise it causes a segmentation fault). The output will need to be scaled either by using *balance* or by multiplying the output by some scaling constant.

### Note

The sampling rate of the orchestra must be 44.1kHz. This is because 44.1kHz is the sampling rate at which the HRTFs were measured. In order to be used at a different rate, the HRTFs would need to be re-sampled at the desired rate.

## Examples

Here is an example of the *hrtfer* opcode. It uses the file *hrtfer.csd* [examples/hrtfer.csd], *HRTFcompact* [examples/HRTFcompact], and *beats.wav* [examples/beats.wav].

### Example 1144. Example of the hrtfer opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# sndload

*sndload* — Loads a sound file into memory for use by *loscilx*

## Description

*sndload* loads a sound file into memory for use by *loscilx*.

### Note

This opcode loads the file into memory but it is not available for use afterwards. In effect it just wastes memory.

## Syntax

```
sndload Sfname[, ifmt[, ichns[, isr[, ibas[, iamp[, istrt    \
[, ilpmod[, ilps[, ilpe]]]]]]]]]
```

## Initialization

*Sfname* - file name as a string constant or variable, string p-field, or a number that is used either as an index to strings set with strset, or, if that is not available, a file name in the format soundin.n is used. If the file name does not include a full path, the file is searched in the current directory first, then those specified by *SSDIR* (if defined), and finally *SFDIR*. If the same file was already loaded previously, it will not be read again, but the parameters ibas, iamp, istrt, ilpmod, ilps, and ilpe are still updated.

*ifmt* (optional, defaults to zero) - default sample format for raw (headerless) sound files; if the file has a header, this is ignored. Can be one of the following:

- 1: do not allow headerless files (fail with an init error)
- 0: use the same format as the one specified on the command line
- 1: 8 bit signed integers
- 2: a-law
- 3: u-law
- 4: 16 bit signed integers
- 5: 32 bit signed integers
- 6: 32 bit floats
- 7: 8 bit unsigned integers
- 8: 24 bit signed integers
- 9: 64 bit floats

*ichns* (optional, defaults to zero) - default number of channels for raw (headerless) sound files; if the file has a header, this is ignored. Zero or negative values are interpreted as 1 channel.

*isr* (optional, defaults to zero) - default sample rate for raw (headerless) sound files; if the file has a header, this is ignored. Zero or negative values are interpreted as the orchestra sample rate (sr).

*ibas* (optional, defaults to zero) - base frequency in Hz. If positive, overrides the value specified in the sound file header; otherwise, the value from the header is used if present, and 1.0 if the file does not include such information.

*iamp* (optional, defaults to zero) - amplitude scale. If non-zero, overrides the value specified in the sound file header (note: negative values are allowed, and will invert the sound output); otherwise, the

value from the header is used if present, and 1.0 if the file does not include such information.

*istrt* (optional, defaults to -1) - starting position in sample frames, can be fractional. If non-negative, overrides the value specified in the sound file header; otherwise, the value from the header is used if present, and 0 if the file does not include such information. Note: even if this parameter is specified, the whole file is still read into memory.

*ilpmod* (optional, defaults to -1) - loop mode, can be one of the following:

- any negative value: use the loop information specified in the sound file header, ignoring ilps and ilpe
- 0: no looping (ilps and ilpe are ignored)
- 1: forward looping (wrap around loop end if it is crossed in forward direction, and wrap around loop start if it is crossed in backward direction)
- 2: backward looping (change direction at loop end if it is crossed in forward direction, and wrap around loop start if it is crossed in backward direction)
- 3: forward-backward looping (change direction at both loop points if they are crossed as described above)

*ilps* (optional, defaults to 0) - loop start in sample frames (fractional values are allowed), or loop end if ilps is greater than ilpe. Ignored unless ilpmod is set to 1, 2, or 3. If the loop points are equal, the whole sample is looped.

*ilpe* (optional, defaults to 0) - loop end in sample frames (fractional values are allowed), or loop start if ilps is greater than ilpe. Ignored unless ilpmod is set to 1, 2, or 3. If the loop points are equal, the whole sample is looped.

# peakk

peakk — Deprecated.

## Description

Deprecated as of version 3.63. Use the *peak* opcode instead.

# pop

`pop` — Pops values from the global stack. Deprecated.

## Description

Pops values from the global stack.

## Syntax

```
xval1, [xval2, ... , xval31] pop  
  
ival1, [ival2, ... , ival31] pop
```

## Initialization

*ival1 ... ival31* - values to be popped from the stack.

## Performance

*xval1 ... xval31* - values to be popped from the stack.

The given values are popped from the stack. The global stack works in LIFO order: after multiple *push* calls, *pop* should be used in reverse order.

Each *push* or *pop* operation can work on a "bundle" of multiple variables. When using *pop*, the number, type, and order of items must match those used by the corresponding *push*. That is, after a 'push Sfoo, ibar', you must call something like 'Sbar, ifoo pop', and not e.g. two separate 'pop' statements.

*push* and *pop* opcodes can take variables of any type (i-, k-, a- and strings). Use of any combination of i, k, a, and S types is allowed. Variables of type 'a' and 'k' are passed at performance time only, while 'i' and 'S' are passed at init time only.

*push/pop* for a, k, i, and S types copy data by value. By contrast, *push\_f* only pushes a "reference" to the f-signal, and then the corresponding *pop\_f* will copy directly from the original variable to its output signal. For this reason, changing the source f-signal of *push\_f* before *pop\_f* is called is not recommended, and if the instrument instance owning the variable that was passed by *push\_f* is deactivated before *pop\_f* is called, undefined behavior may occur.

Any stack errors (trying to push when there is no more space, or pop from an empty stack, inconsistent number or type of arguments, etc.) are fatal and terminate performance.

## See also

## Examples

Here is an example of the *pop* opcode. It uses the file *pop.csd* [examples/pop.csd].

2006

Deprecated as of version 6.04.

## pop\_f

`pop_f` — Pops an f-sig frame from the global stack. Deprecated.

## Description

Pops an f-sig frame from the global stack.

## Syntax

```
fsig pop_f
```

## Performance

*fsig* - f-signal to be popped from the stack.

The values are popped the stack. The global stack must be initialized before used, and its size must be set. The global stack works in LIFO order: after multiple *push\_f* calls, *pop\_f* should be used in reverse order.

*push/pop* for a, k, i, and S types copy data by value. By contrast, *push\_f* only pushes a "reference" to the f-signal, and then the corresponding *pop\_f* will copy directly from the original variable to its output signal. For this reason, changing the source f-signal of *push\_f* before *pop\_f* is called is not recommended, and if the instrument instance owning the variable that was passed by *push\_f* is deactivated before *pop\_f* is called, undefined behavior may occur.

*push\_f* and *pop\_f* can only take a single argument, and the data is passed both at init and performance time.

Any stack errors (trying to push when there is no more space, or pop from an empty stack, inconsistent number or type of arguments, etc.) are fatal and terminate performance.

# push

`push` — Pushes a value into the global stack. Deprecated.

## Description

Pushes a value into the global stack.

## Syntax

```
push  xval1, [xval2, ... , xval31]  
  
push  ival1, [ival2, ... , ival31]
```

## Initialization

*ival1* ... *ival31* - values to be pushed into the stack.

## Performance

*xval1* ... *xval31* - values to be pushed into the stack.

The given values are pushed into the global stack as a bundle. The global stack works in LIFO order: after multiple *push* calls, *pop* should be used in reverse order.

Each *push* or *pop* operation can work on a "bundle" of multiple variables. When using *pop*, the number, type, and order of items must match those used by the corresponding *push*. That is, after a 'push Sfoo, ibar', you must call something like 'Sbar, ifoo pop', and not e.g. two separate 'pop' statements.

*push* and *pop* opcodes can take variables of any type (i-, k-, a- and strings). Use of any combination of i, k, a, and S types is allowed. Variables of type 'a' and 'k' are passed at performance time only, while 'i' and 'S' are passed at init time only.

*push/pop* for a, k, i, and S types copy data by value. By contrast, *push\_f* only pushes a "reference" to the f-signal, and then the corresponding *pop\_f* will copy directly from the original variable to its output signal. For this reason, changing the source f-signal of *push\_f* before *pop\_f* is called is not recommended, and if the instrument instance owning the variable that was passed by *push\_f* is deactivated before *pop\_f* is called, undefined behavior may occur.

Any stack errors (trying to push when there is no more space, or pop from an empty stack, inconsistent number or type of arguments, etc.) are fatal and terminate performance.

## Examples

Here is an example of the *push* opcode. It uses the file *push.csd* [examples/push.csd].

### Example 1146. Example of the push opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# soundout

*soundout* — Deprecated. Writes audio output to a disk file.

## Description

### Note

The usage of *soundout* is discouraged. Please use *fout* instead.

Writes audio output to a disk file.

## Syntax

```
soundout  asig1, ifilcod [, iformat]
```

## Initialization

*ofilcod* -- integer or character-string denoting the destination soundfile name. An integer denotes the file *soundin.filcod*; a character-string (in double quotes, spaces permitted) gives the filename itself, optionally a full pathname. If not a full path, the named file is sought first in the current directory, then in that given by the environment variable *SSDIR* (if defined) then by *SFDIR*. See also *GEN01*.

*iformat* (optional, default=0) -- specifies the audio data file format:

- 1 = 8-bit signed char (high-order 8 bits of a 16-bit integer)
- 2 = 8-bit A-law bytes
- 3 = 8-bit U-law bytes
- 4 = 16-bit short integers
- 5 = 32-bit long integers
- 6 = 32-bit floats

If *iformat* = 0 it is taken from the soundfile header, and if no header from the Csound -o command-line flag. The default value is 0.

## Performance

*soundout* writes audio output to a disk file.

### Note

Use of *fout* is recommended instead of *soundout*

## See Also

# soundouts

`soundouts` — Deprecated. Writes audio output to a disk file.

## Description

### Note

The usage of *soundouts* is discouraged. Please use *fout* instead.

Writes audio output to a disk file.

## Syntax

```
soundouts asigl, asigr, ifilcod [, iformat]
```

## Initialization

*ofilcod* -- integer or character-string denoting the destination soundfile name. An integer denotes the file `soundout.ifilcod`; a character-string (in double quotes, spaces permitted) gives the filename itself, optionally a full pathname. If not a full path, the named file is written relative to the directory given by the SF-DIR environment variable if defined, or the current directory. See also *GEN01*.

*iformat* (optional, default=0) -- specifies the audio data file format:

- 1 = 8-bit signed char (high-order 8 bits of a 16-bit integer)
- 4 = 16-bit short integers
- 5 = 32-bit long integers
- 6 = 32-bit floats

If *iformat* = 0 it is taken from the Csound *-o* command-line flag. The default value is 0.

## Performance

*soundouts* writes stereo audio output to a disk file in raw (headerless) format without 0dBFS scaling. The expected range of the audio signals depends on the selected sample format.

### Note

Use of *fout* is recommended instead of *soundouts*

## See Also

# stack

`stack` — Initializes the stack. Deprecated.

## Description

Initializes and sets the size of the global stack.

## Syntax

```
stack  istackSize
```

## Initialization

*iStackSize* - size of the stack in bytes.

## Performance

Csound implements a single global stack. Initializing the stack with the `stack` opcode is not required - it is optional, and if not done, the first use of `push` or `push_f` will automatically create a stack of 32768 bytes. Otherwise, `stack` is normally called from the orchestra header, and takes a stack size parameter in bytes (there is an upper limit of about 16 MB). Once set, the stack size is fixed and cannot be changed during performance.

The global stack works in LIFO order: after multiple `push` calls, `pop` should be used in reverse order.

Each `push` or `pop` operation can work on a "bundle" of multiple variables. When using `pop`, the number, type, and order of items must match those used by the corresponding `push`. That is, after a 'push Sfoo, ibar', you must call something like 'Sbar, ifoo pop', and not e.g. two separate 'pop' statements.

`push` and `pop` opcodes can take variables of any type (i-, k-, a- and strings). Variables of type 'a' and 'k' are passed at performance time only, while 'i' and 'S' are passed at init time only.

`push/pop` for a, k, i, and S types copy data by value. By contrast, `push_f` only pushes a "reference" to the f-signal, and then the corresponding `pop_f` will copy directly from the original variable to its output signal. For this reason, changing the source f-signal of `push_f` before `pop_f` is called is not recommended, and if the instrument instance owning the variable that was passed by `push_f` is deactivated before `pop_f` is called, undefined behavior may occur.

Any stack errors (trying to push when there is no more space, or pop from an empty stack, inconsistent number or type of arguments, etc.) are fatal and terminate performance.

## Examples

Here is an example of the `stack` opcode. It uses the file `stack.csd` [examples/stack.csd].

### Example 1147. Example of the stack opcode.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# The Utility Programs

Dan Ellis, MIT Media Lab

The Csound Utilities are *soundfile preprocessing* programs that return information on a soundfile or create some analyzed version of it for use by certain Csound generators. Though different in goals, they share a common soundfile access mechanism and are describable as a set. The Soundfile Utility programs can be invoked in two equivalent forms:

```
csound [-U utilname] [flags] [filenames]
```

```
utilname [flags] [filenames]
```

In the first, the utility is invoked as part of the Csound executable, while in the second it is called as a standalone program. The second is smaller by about 200K, but the two forms are identical in function. The first is convenient in not requiring the maintenance and use of several independent programs - one program does all. When using this form, a *-U flag* detected in the command line will cause all subsequent flags and names to be interpreted as per the named utility; i.e. Csound generation will not occur, and the program will terminate at the end of utility processing.

## Directories.

Filenames are of two kinds, source soundfiles and resultant analysis files. Each has a hierarchical naming convention, influenced by the directory from which the Utility is invoked. Source soundfiles with a full pathname (begins with dot (.), slash (/), or for ThinkC includes a colon (:)), will be sought only in the directory named. Soundfiles without a path will be sought first in the current directory, then in the directory named by the *SSDIR* environment variable (if defined), then in the directory named by *SFDIR*. An unsuccessful search will return a "cannot open" error.

Resultant analysis files are written into the current directory, or to the named directory if a path is included. It is tidy to keep analysis files separate from sound files, usually in a separate directory known to the *SADIR* variable. Analysis is conveniently run from within the *SADIR* directory. When an analysis file is later invoked by a Csound generator it is sought first in the current directory, then in the directory defined by *SADIR*.

## Soundfile Formats.

Csound can read and write audio files in a variety of formats. Write formats are described by Csound command flags. On reading, the format is determined from the soundfile header, and the data automatically converted to floating-point during internal processing. When Csound is installed on a host with local soundfile conventions (SUN, NeXT, Macintosh) it may conditionally include local packaging code which creates soundfiles not portable to other hosts. However, Csound on any host can always generate and read AIFF files, which is thus a portable format. Sampled sound libraries are typically AIFF, and the variable *SSDIR* usually points to a directory of such sounds. If defined, the *SSDIR* directory is in the search path during soundfile access. Note that some AIFF sampled sounds have an audio looping feature for sustained performance; the analysis programs will traverse any loop segment once only.

For soundfiles without headers, an SR value may be supplied by the *-r flag* (or its default). If both the *SR header* and the command-line flag are present, the flag value will override the header.

When sound is accessed by the audio Analysis programs, only a single channel is read. For stereo or quad files, the default is channel one; alternate channels may be obtained on request.

## Analysis File Generation (ATSA, CVANAL, HETRO, LPANAL, PVANAL)

The following utilities exist for Soundfile analysis:

- *ATSA*: ATS analysis for use with the Csound *ATS Resynthesis* opcodes.
- *CVANAL*: Impulse Response Fourier Analysis for *convolve* operator.
- *HETRO*: Heterodyne analysis for the Csound *adsyn* generator.
- *LPANAL*: Linear predictive coding analysis for the Csound *Linear Predictive Coding (LPC) Resynthesis* opcodes.
- *PVANAL*: Phase vocoder analysis for the Csound *pvoc* generator.

## atsa

atsa — Performs ATS analysis on a soundfile.

### Description

ATS analysis for use with the Csound *ATS Resynthesis* opcodes.

### Syntax

```
csound -U atsa [flags] infilename outfilename
```

### Initialization

The following flags can be set for atsa (The default values are stated in parenthesis):

- b start (0.000000 seconds)
- e duration (0.000000 seconds or end)
- l lowest frequency (20.000000 Hertz)
- H highest frequency (20000.000000 Hertz)
- d frequency deviation (0.100000 of partial freq.)
- c window cycles (4 cycles)
- w window type (type: 1) (Options: 0=BLACKMAN, 1=BLACKMAN\_H, 2=HAMMING, 3=VONHANN)
- h hop size (0.250000 of window size)
- m lowest magnitude (-60.000000)
- t track length (3 frames)
- s min. segment length (3 frames)
- g min. gap length (3 frames)
- T SMR threshold (30.000000 dB SPL)
- S min. segment SMR (60.000000 dB SPL)
- P last peak contribution (0.000000 of last peak's parameters)
- M SMR contribution (0.500000)
- F File Type (type: 4) (Options: 1=amp.and freq. only, 2=amp.,freq. and phase, 3=amp.,freq. and residual, 4=amp.,freq.,phase, and residual)

### Parameters

ATS analysis was devised by Juan Pampin. For complete information on ATS visit: <http://www-ccrma.stanford.edu/~juan/ATS.html>.

Analysis parameters must be carefully tuned for the Analysis Algorithm (ATSA) to properly capture the nature of the signal to be analyzed. As there are a significant number of them, ATSH offers the possibility of Saving/Loading them in a Binary File carrying the extension ".apf". The extension is not mandatory, but recommended. A brief explanation of each Analysis Parameters follows:

1. Start (secs.): the starting time of the analysis in seconds.
2. Duration (secs.): the duration time of the analysis in seconds. A zero means the whole duration of the input sound file.
3. Lowest Frequency (Hz.): this parameter will partially determine the size of the Analysis Window to be used. To compute the size of the Analysis Window, the period of the Lowest Frequency in samples (SR / LF) is multiplied by the number of cycles of it the user wants to fit in the Analysis Window (see parameter 6). This value is rounded to the next power of two to determine the size of

the FFT for the analysis. The remaining samples are zero-padded. If the signal is a single, harmonic sound, then the value of the Lowest Frequency should be its fundamental frequency or a sub-harmonic of it. If it is not harmonic, then its lowest significant frequency component may be a good starting value.

4. Highest Frequency (Hz.): highest frequency to be taken into account for Peak Detection. Once it is determined that no relevant information is found beyond a certain frequency, the analysis may be faster and more accurate setting the Highest Frequency parameter to that value.
5. Frequency Deviation (Ratio): frequency deviation allowed for each peak in the Peak Continuation Algorithm, as a ratio of the frequency involved. For instance, considering a peak at 440 Hz and a Deviation of .1 will produce that the Peak Continuation Algorithm will only try to find candidates for its continuation between 396 and 484 Hz (10% above and below the frequency of the peak). A small value is likely to produce more trajectories whilst a large value will reduce them, but at the cost of rendering information difficult to be further processed.
6. Number of Cycles of Lowest Frequency to fit in Analysis Window: this will also partially determine the size of the Fourier Analysis Window to be used. See Parameter 3. For single harmonic signals, it is supposed to be more than one (typically 4).
7. Hop Size (Ratio): size of the gap between one Analysis Window and the next expressed as a ratio of the Window Size. For instance, a Hop Size value of .25 will "jump" by 512 samples (Windows will overlap for a 75% of their size). This parameter will also determine the size of the analysis frames obtained. Signals that change their spectra very fast (such as Speech sounds) may need a high frame rate in order to properly track their changes.
8. Amplitude Threshold (dB): the highest amplitude value to be taken into account for Peak Detection.
9. Window Type: the shape of the smoothing function to be used for the Fourier Analysis. There are four choices available at present: Blackman, Blackman-Harris, Von Hann, and Hanning. Precise specifications about them are easily found on D.S.P. bibliography.
- 10 Track Length (Frames): The Peak Continuation Algorithm will "look-back" by Length frames in order to do its job better, preventing frequency trajectories from curving too much and loosing stability. However, a large value for this parameter will slow down the analysis significantly.
- 11 Minimal Segment Length (Frames): once the analysis is done, the spectral data can be further "cleaned" up during post-processing. Trajectories shorter than this value are suppressed if their average SMR is below Minimal Segment SMR (see parameters 16 and 14). This might help to avoid non-relevant sudden changes while keeping a high frame rate, reducing also the number of intermittent sinusoids during synthesis.
- 12 Minimal Gap Length (Frames): as parameter 11, this one is also used to clean up the data during post-processing. In this case, gaps (zero amplitude values, i.e. theoretical "silence") longer than Length frames are filled up with amplitude/frequency values obtained by linear interpolation of the adjacent active frames. This parameter prevents sudden interruptions of stable trajectories while keeping a high frame rate.
- 13 SMR Threshold (dB SPL): also a post-processing parameter, the SMR Threshold is used to eliminate partials with low averages.
- 14 Minimal Segment SMR (dB SPL): this parameter is used in combination with parameter 11. Short segments with SMR average below this value will be removed during post-processing.
- 15 Last Peak Contribution (0 to 1): as explained in Parameter 10, the Peak Continuation Algorithm "looks-back" several number of frames to do its job better. This parameter will help to weight the contribution of the first precedent peak over the others. A zero value means that all precedent peaks (to the size of Parameter 10) are equally taken in account.

- 16 SMR Contribution (0 to 1): In addition to the proximity in frequency of the peaks, the ATS Peak Continuation Algorithm may use psycho-acoustic information (the Signal-to-Mask-Ratio, or SMR) to improve the perceptual results. This parameter indicates how much the SMR information is used during tracking. For instance, a value of .5 makes the Peak Continuation Algorithm to use a 50% of SMR information and a 50% of Frequency Proximity information to decide which is the best candidate to continue a sinusoidal track.

## Examples

The following command:

```
atsa -b0.1 -e1 -l100 -H10000 -w2 audiofile.wav audiofile.ats
```

Generates the ATS analysis file 'audiofile.ats' from the original 'audiofile.wav' file. It begins analysis from second 0.1 of the file and the analysis is performed for 1 second thereafter. The lowest frequency stored is 100 Hz and the highest is 10kHz. A Hamming window is used for each analysis frame.

## cvanal

**cvanal** — Converts a soundfile into a single Fourier transform frame.

### Description

Impulse Response Fourier Analysis for *convolve* operator

### Syntax

```
csound -U cvanal [flags] infilename outfilename  
  
cvanal [flags] infilename outfilename
```

### Initialization

*cvanal* -- converts a soundfile into a single Fourier transform frame. The output file can be used by the *convolve* operator to perform Fast Convolution between an input signal and the original impulse response. Analysis is conditioned by the flags below. A space is optional between the flag and its argument.

**-s rate** -- sampling rate of the audio input file. This will over-ride the srate of the soundfile header, which otherwise applies. If neither is present, the default is 10000.

**-c channel** -- channel number sought. If omitted, the default is to process all channels. If a value is given, only the selected channel will be processed.

**-b begin** -- beginning time (in seconds) of the audio segment to be analyzed. The default is 0.0

**-d duration** -- duration (in seconds) of the audio segment to be analyzed. The default of 0.0 means to the end of the file.

**-X** -- write machine independent format analysis file.

### Examples

```
cvanal asound cvfile
```

will analyze the soundfile "asound" to produce the file "cvfile" for the use with *convolve*.

To use data that is not already contained in a soundfile, a soundfile converter that accepts text files may be used to create a standard audio file, e.g., the .DAT format for SOX. This is useful for implementing FIR filters.

### Files

The output file has a special *convolve* header, containing details of the source audio file. The analysis data is stored as “float”, in rectangular (real/imaginary) form.

### Note

The analysis file is *not* system independent! Ensure that the original impulse recording/data is retained. If/when required, the analysis file can be recreated.

## Credits

Author: Greg Sullivan

Based on algorithm given in *Elements Of Computer Music*, by F. Richard Moore.

## hetro

**hetro** — Decomposes an input soundfile into component sinusoids.

### Description

Hetrodyne filter analysis for the Csound *adsyn* generator.

### Syntax

```
csound -U hetro [flags] infilename outfilename  
  
hetro [flags] infilename outfilename
```

### Initialization

*hetro* takes an input soundfile, decomposes it into component sinusoids, and outputs a description of the components in the form of breakpoint amplitude and frequency tracks. Analysis is conditioned by the control flags below. A space is optional between flag and value.

**-s srate** -- sampling rate of the audio input file. This will over-ride the srate of the soundfile header, which otherwise applies. If neither is present, the default is 10000. Note that for *adsyn* synthesis the srate of the source file and the generating orchestra need not be the same.

**-c channel** -- channel number sought. The default is 1.

**-b begin** -- beginning time (in seconds) of the audio segment to be analyzed. The default is 0.0

**-d duration** -- duration (in seconds) of the audio segment to be analyzed. The default of 0.0 means to the end of the file. Maximum length is 32.766 seconds.

**-f begfreq** -- estimated starting frequency of the fundamental, necessary to initialize the filter analysis. The default is 100 (cps).

**-h partials** -- number of harmonic partials sought in the audio file. Default is 10, maximum is a function of memory available.

**-M maxamp** -- maximum amplitude summed across all concurrent tracks. The default is 32767.

**-m minamp** -- amplitude threshold below which a single pair of amplitude/frequency tracks is considered dormant and will not contribute to output summation. Typical values: 128 (48 db down from full scale), 64 (54 db down), 32 (60 db down), 0 (no thresholding). The default threshold is 64 (54 db down).

**-n brkpts** -- initial number of analysis breakpoints in each amplitude and frequency track, prior to thresholding (**-m**) and linear breakpoint consolidation. The initial points are spread evenly over the duration. The default is 256.

**-l cutfreq** -- substitute a 3rd order Butterworth low-pass filter with cutoff frequency *cutfreq* (in Hz), in place of the default averaging comb filter. The default is 0 (don't use).

### Performance

As of Csound 4.08, *hetro* can write SDIF output files if the output file name ends with ".sdif" or ".SDIF". See the *sdif2ad* utility for more information about the Csound's SDIF support.

### Examples

---

```
hetro -s44100 -b.5 -d2.5 -h16 -M24000 audiofile.test adsynfile7
```

This will analyze 2.5 seconds of channel 1 of a file "audiofile.test", recorded at 44.1 kHz, beginning .5 seconds from the start, and place the result in a file "adsynfile7". We request just the first 16 harmonics of the sound, with 256 initial breakpoint values per amplitude or frequency track, and a peak summation amplitude of 24000. The fundamental is estimated to begin at 100 Hz. Amplitude thresholding is at 54 db down.

The Butterworth LPF is not enabled.

## File Format

The output file contains time-sequenced amplitude and frequency values for each partial of an additive complex audio source. The information is in the form of breakpoints (time, value, time, value, ....) using 16-bit integers in the range 0 - 32767. Time is given in milliseconds, and frequency in Hertz (cps). The breakpoint data is exclusively non-negative, and the values -1 and -2 uniquely signify the start of new amplitude and frequency tracks. A track is terminated by the value 32767. Before being written out, each track is data-reduced by amplitude thresholding and linear breakpoint consolidation.

A component partial is defined by two breakpoint sets: an amplitude set, and a frequency set. Within a composite file these sets may appear in any order (amplitude, frequency, amplitude ....; or amplitude, amplitude..., then frequency, frequency,...). During *adsyn* resynthesis the sets are automatically paired (amplitude, frequency) from the order in which they were found. There should be an equal number of each.

A legal *adsyn* control file could have following format:

```
-1 time1 value1 ... timeK valueK 32767 ; amplitude breakpoints for partial 1
-2 time1 value1 ... timeL valueL 32767 ; frequency breakpoints for partial 1
-1 time1 value1 ... timeM valueM 32767 ; amplitude breakpoints for partial 2
-2 time1 value1 ... timeN valueN 32767 ; frequency breakpoints for partial 2
-2 time1 value1 .....                                ; pairable tracks for partials 3 and 4
-1 time1 value1 .....                                ;
-1 time2 value1 .....                                ;
```

## Ipanal

**Ipanal** — Performs both linear predictive and pitch-tracking analysis on a soundfile.

### Description

Linear predictive analysis for the Csound *Linear Predictive Coding (LPC) Resynthesis* opcodes.

### Syntax

```
csound -U lpanal [flags] infilename outfilename  
  
lpanal [flags] infilename outfilename
```

### Initialization

*Ipanal* performs both lpc and pitch-tracking analysis on a soundfile to produce a time-ordered sequence of *frames* of control information suitable for Csound resynthesis. Analysis is conditioned by the control flags below. A space is optional between the flag and its value.

**-a** -- [alternate storage] asks Ipanal to write a file with filter poles values rather than the usual filter coefficient files. When *lpread* / *lpreson* are used with pole files, automatic stabilization is performed and the filter should not get wild. (This is the default in the Windows GUI) - Changed by Marc Resibois.

**-s srate** -- sampling rate of the audio input file. This will over-ride the srate of the soundfile header, which otherwise applies. If neither is present, the default is 10000.

**-c channel** -- channel number sought. The default is 1.

**-b begin** -- beginning time (in seconds) of the audio segment to be analyzed. The default is 0.0

**-d duration** -- duration (in seconds) of the audio segment to be analyzed. The default of 0.0 means to the end of the file.

**-p npoles** -- number of poles for analysis. The default is 34, the maximum 50.

**-h hopsize** -- hop size (in samples) between frames of analysis. This determines the number of frames per second (srate / hopsize) in the output control file. The analysis framesize is hopsize \* 2 samples. The default is 200, the maximum 500.

**-C string** -- text for the comments field of the lpfile header. The default is the null string.

**-P mincps** -- lowest frequency (in Hz) of pitch tracking. -P0 means no pitch tracking.

**-Q maxcps** -- highest frequency (in Hz) of pitch tracking. The narrower the pitch range, the more accurate the pitch estimate. The defaults are -P70, -Q200.

**-v verbosity** -- level of terminal information during analysis.

- 0 = none
- 1 = verbose
- 2 = debug

The default is 0.

*-X* -- write machine independent format analysis file.

## Examples

```
lpanal -a -p26 -d2.5 -P100 -Q400 audiofile.test lpfilt22
```

will analyze the first 2.5 seconds of file "audiofile.test", producing srate/200 frames per second, each containing 26-pole filter coefficients and a pitch estimate between 100 and 400 Hertz. Stabilized (-a) output will be placed in "lpfil22" in the current directory.

## File Format

Output is a file comprised of an identifiable header plus a set of frames of floating point analysis data. Each frame contains four values of pitch and gain information, followed by *npoles* filter coefficients. The file is readable by Csound's *lpread*.

*lpanal* is an extensive modification of Paul Lanksy's lpc analysis programs.

## pvanal

*pvanal* — Converts a soundfile into a series of short-time Fourier transform frames.

### Description

Fourier analysis for the Csound *pvoc* generator

### Syntax

```
csound -U pvanal [flags] infilename outfilename  
  
pvanal [flags] infilename outfilename
```

### Pvanal extension to create a PVOC-EX file.

The standard Csound utility program *pvanal* has been extended to enable a PVOC-EX format file to be created, using the existing interface. To create a PVOC-EX file, the file name must be given the required extension, “.pxv”, e.g “test.pvx”. The requirement for the FFT size to be a power of two is here relaxed, and any positive value is accepted; odd numbers are rounded up internally. However, power-of-two sizes are still to be preferred for all normal applications.

The channel select flags are ignored, and all source channels will be analysed and written to the output file, up to a compiler-set limit of eight channels. The analysis window size (*iwinsize*) is set internally to double the FFT size.

### Initialization

*pvanal* converts a soundfile into a series of short-time Fourier transform (STFT) frames at regular timepoints (a frequency-domain representation). The output file can be used by *pvoc* to generate audio fragments based on the original sample, with timescales and pitches arbitrarily and dynamically modified. Analysis is conditioned by the flags below. A space is optional between the flag and its argument.

*-s srate* -- sampling rate of the audio input file. This will over-ride the srate of the soundfile header, which otherwise applies. If neither is present, the default is 10000.

*-c channel* -- channel number sought. The default is 1.

*-b begin* -- beginning time (in seconds) of the audio segment to be analyzed. The default is 0.0

*-d duration* -- duration (in seconds) of the audio segment to be analyzed. The default of 0.0 means to the end of the file.

*-n frmsiz* -- STFT frame size, the number of samples in each Fourier analysis frame. Must be a power of two, in the range 16 to 16384. For clean results, a frame must be larger than the longest pitch period of the sample. However, very long frames result in temporal “smearing” or reverberation. The bandwidth of each STFT bin is determined by sampling rate / frame size. The default framesize is the smallest power of two that corresponds to more than 20 milliseconds of the source (e.g. 256 points at 10 kHz sampling, giving a 25.6 ms frame).

*-w windfact* -- Window overlap factor. This controls the number of Fourier transform frames per second. Csound’s *pvoc* will interpolate between frames, but too few frames will generate audible distortion; too many frames will result in a huge analysis file. A good compromise for windfact is 4, meaning that each input point occurs in 4 output windows, or conversely that the offset between successive STFT frames is framesize/4. The default value is 4. Do not use this flag with *-h*.

*-h hopsize* -- STFT frame offset. Converse of above, specifying the increment in samples between successive frames of analysis (see also *lpanal*). Do not use with *-w*.

*-H* -- Use a Hamming window instead of the default von Hann window.

*-K* -- Use a Kaiser window instead of the default von Hann window. The Kaiser parameter default is 6.8, but can be set with the *-B* option.

*-B beta* -- Set the beta parameter for any Kaiser window used to the floating point value beta.

## Examples

```
pvanal asound pvfile
```

will analyze the soundfile "asound" using the default frmsiz and windfact to produce the file "pvfile" suitable for use with pvoc.

## Files

The output file has a special *pvoc* header containing details of the source audio file, the analysis frame rate and overlap. Frames of analysis data are stored as float, with the magnitude and “frequency” (in Hz) for the first  $N/2 + 1$  Fourier bins of each frame in turn. “Frequency” encodes the phase increment in such a way that for strong harmonics it gives a good indication of the true frequency. For low amplitude or rapidly moving harmonics it is less meaningful.

## Diagnostics

Prints total number of frames, and frames completed every 20th frame.

## File Queries (SNDINFO)

The following utilities exist for Soundfile quuery:

- *SNDINFO*: Displays information about a soundfile.

## **sndinfo**

**sndinfo** — Displays information about a soundfile.

### **Description**

Get basic information about one or more soundfiles.

### **Syntax**

```
csound -U sndinfo [options] soundfilenames ...  
  
sndinfo [options] soundfilenames ...
```

### **Initialization**

*sndinfo* will attempt to find each named file, open it for reading, read in the soundfile header, then print a report on the basic information it finds. The order of search across soundfile directories is as described above. If the file is of type AIFF, some further details are listed first.

There are two option types:

1. *-i* or *-I* will print instrument information, which includes looping. The option continues until a *-i0* option.
2. The other option is *-b* which prints the broadcast information for WAV files. It can similarly be negated with *-b0*.

### **Examples**

```
csound -U sndinfo test Bosendorfer/"BOSEN mf A0 st" foo foo2
```

where the environment variables SFDIR = /u/bv/sound, and SSDIR = /so/bv/Samples, might produce the following:

```
util SNDINFO:  
/u/bv/sound/test:  
    srate 22050, monaural, 16 bit shorts, 1.10 seconds  
    headersiz 1024, datasiz 48500 (24250 sample frames)  
  
/so/bv/Samples/Bosendorfer/BOSEN mf A0 st: AIFF, 197586 stereo samples, base Frq 261.6 (MIDI 60),  
    AIFF soundfile, looping with modes 1, 0  
    srate 44100, stereo, 16 bit shorts, 4.48 seconds  
    headersiz 402, datasiz 790344 (197586 sample frames)  
  
/u/bv/sound/foo:  
    no recognizable soundfile header  
  
/u/bv/sound/foo2:  
    couldn't find
```

## **File Conversion (HET\_IMPORT, HET\_EXPORT, PVLOOK, PV\_EXPORT, PV\_IMPORT, SDIF2AD, SRCONV)**

The following utilities exist for file conversion:

- *HET\_EXPORT*: Exports a .het (produced by *HETRO*) to a comma separated text file.
- *HET\_IMPORT*: Generates a .het (in the format produced by *HETRO*) from a comma separated text file for usage with the *adsyn* generator.
- *PVLOOK*: View formatted text output of STFT analysis files.
- *PV\_EXPORT*: Converts a file generated by *PVANAL* to a text file.
- *PV\_IMPORT*: Converts a text file (in the format generated by *PV\_EXPORT*) to a *PVANAL* format file to be used with the *pvoc* opcode.
- *SDIF2AD*: Converts SDIF files to files usable by *adsynt*.
- *SRCINV*: Converts the sample rate of an audio file.

## dnoise

dnoise — Reduces noise in a file.

### Description

This is a noise reduction scheme using frequency-domain noise-gating.

### Syntax

```
dnoise [flags] -i noise_ref_file -o output_soundfile input_soundfile
```

### Initialization

Dnoise specific flags:

- (*no flag*) input soundfile to be denoised
- *-i fname* input reference noise soundfile
- *-o fname* output soundfile
- *-N fnum* # of bandpass filters (default: 1024)
- *-w fovlp* filter overlap factor: {0,1,(2),3} DON'T USE *-w* AND *-M*
- *-M awlen* analysis window length (default: N-1 unless *-w* is specified)
- *-L swlen* synthesis window length (default: M)
- *-D dfac* decimation factor (default: M/8)
- *-b btim* begin time in noise reference soundfile (default: 0)
- *-B smpst* starting sample in noise reference soundfile (default: 0)
- *-e etim* end time in noise reference soundfile (default: end of file)
- *-E smpend* final sample in noise reference soundfile (default: end of file)
- *-t thr* threshold above noise reference in dB (default: 30)
- *-S gfact* sharpness of noise-gate turnoff, range: 1 to 5 (default: 1)
- *-n numfrm* number of FFT frames to average over (default: 5)
- *-m mingain* minimum gain of noise-gate when off in dB (default: -40)

Soundfile format options:

- *-A* AIFF format output
- *-W* WAV format output

- **-J** IRCAM format output
- **-h** skip soundfile header (not valid for AIFF/WAV output)
- **-8** 8-bit unsigned char sound samples
- **-c** 8-bit signed\_char sound samples
- **-a** alaw sound samples
- **-u** ulaw sound samples
- **-s** short\_int sound samples
- **-l** long\_int sound samples
- **-f** float sound samples. Floats also supported for WAV files. (New in Csound 3.47.)

Additional options:

- **-R** verbose - print status info
- **-H [N]** print a heartbeat character at each soundfile write.
- **-- fname** output to log file fname
- **-V** verbose - print status info

## Note

DNOISE also looks at the environment variable SFOUTYP to determine soundfile output format.

The **-i** flag is used for a reference noise file (normally created from a short section of the denoised file, where only noise is audible). The input soundfile to be denoised can be given anywhere on the command line, without a flag.

## Performance

This is a noise reduction scheme using frequency-domain noise-gating. This should work best in the case of high signal-to-noise with hiss-type noise.

The algorithm is that suggested by Moorer & Berger in “Linear-Phase Bandsplitting: Theory and Applications” presented at the 76th Convention 1984 October 8-11 New York of the Audio Engineering Society (preprint #2132) except that it uses the Weighted Overlap-Add formulation for short-time Fourier analysis-synthesis in place of the recursive formulation suggested by Moorer & Berger. The gain in each frequency bin is computed independently according to

$$\text{gain} = g_0 + (1-g_0) * [\text{avg} / (\text{avg} + \text{th} * \text{th} * \text{nref})] ^ \text{sh}$$

where *avg* and *nref* are the mean squared signal and noise respectively for the bin in question. (This is slightly different than in Moorer & Berger.)

The critical parameters *th* and *g0* are specified in dB and internally converted to decimal values. The *nref* values are computed at the start of the program on the basis of a noise\_soundfile (specified in the command line) which contains noise without signal.

The *avg* values are computed over a rectangular window of *m* FFT frames looking both ahead and behind the current time. This corresponds to a temporal extent of *m\*D/R* (which is typically *(m\*N/8)/R*). The default settings of *N*, *M*, and *D* should be appropriate for most uses. A higher sample rate than 16 KHz might indicate a higher *N*.

## **het\_export**

**het\_export** — Converts a .het file to a comma separated text file.

### **Syntax**

```
het_export het_file cstext_file  
csound -U het_export het_file cstext_file
```

### **Initialization**

*het\_file* - Name of the input .het file.

*cstext\_file* - Name of the output comma-separated text file.

The *het\_export* utility generates a comma-separated text file for manual editing of a .het file produced by the *HETRO* utility. It can be used in combination with *het\_import* to produce data for the *adsyn* generator.

### **Credits**

Author: John ffitch

1995

## het\_import

het\_import — Converts a comma-separated text file to a .het file.

### Syntax

```
het_import cstext_file het_file  
csound -U het_import cstext_file het_file
```

### Initialization

*cstext\_file* - Name of the input comma-separated text file.

*het\_file* - Name of the output .het file.

The *het\_import* utility generates a *.het* file usable with the *adsyn* generator. It can be used in combination with *het\_export* to modify sound analysis made by the *HETRO* utility.

# pvlook

**pvlook** — View formatted text output of STFT analysis files.

## Description

View formatted text output of STFT analysis files created with *pvanal*.

## Syntax

```
csound -U pvlook [flags] infilename
```

**pvlook** [flags] infilename

## Initialization

*pylook* reads a file, and frequency and amplitude trajectories for each of the analysis bins, in readable text form. The file is assumed to be an STFT analysis file created by *pvanal*. By default, the entire file is processed.

**-bb** *n* -- begin at analysis bin number *n*, numbered from 1. Default is 1.

**-eb *n*** -- end at analysis bin number *n*. Defaults to the highest.

*-bf n* -- begin at analysis frame number *n*, numbered from 1. Defaults to 1.

**-ef** *n* -- end at analysis frame number *n*. Defaults to the highest.

**-i** -- prints values as integers. Defaults to floating point.

## **pv\_export**

**pv\_export** — Converts a .pxv file to a comma separated text file.

### **Syntax**

```
pv_export pv_file cstext_file  
csound -U pv_export pv_file cstext_file
```

### **Initialization**

*pv\_file* - Name of the input .pxv file.

*cstext\_file* - Name of the output comma-separated text file.

The *pv\_export* utility generates a comma-separated text file for manual editing of a .pxv file produced by the *PVANAL* utility. It can be used in combination with *pv\_import* to produce data for the *pvoc* generator.

### **Credits**

Author: John ffitch

1995

## **pv\_import**

**pv\_import** — Converts a comma-separated text file to a .pvx file.

### **Syntax**

```
pv_import cstext_file pv_file  
csound -U pv_import cstext_file pv_file
```

### **Initialization**

*cstext\_file* - Name of the input comma-separated text file.

*pv\_file* - Name of the output .pvx file.

The *pv\_import* utility generates a .pvx file usable with the *pvoc* generator. It can be used in combination with *pv\_export* to modify sound analysis made by the *PVANAL* utility.

## sdif2ad

sdif2ad — Converts SDIF files to files usable by adsyn.

### Description

Convert files Sound Description Interchange Format (SDIF) to the format usable by Csound's *adsyn* op-code. As of Csound version 4.10, *sdif2ad* was available only as a standalone program for Windows console and DOS.

### Syntax

```
sdif2ad [flags] infilename outfilename
```

### Initialization

Flags:

- *-sN* -- apply amplitude scale factor N
- *-pN* -- keep only the first N partials. Limited to 1024 partials. The source partial track indices are used directly to select internal storage. As these can be arbitrary values, the maximum of 1024 partials may not be realized in all cases.
- *-r* -- byte-reverse output file data. The byte-reverse option is there to facilitate transfer across platforms, as Csound's *adsyn* file format is not portable.

If the filename passed to *hetro* has the extension “.sdif”, data will be written in SDIF format as 1TRC frames of additive synthesis data. The utility program *sdif2ad* can be used to convert any SDIF file containing a stream of 1TRC data to the Csound *adsyn* format. *sdif2ad* allows the user to limit the number of partials retained, and to apply an amplitude scaling factor. This is often necessary, as the SDIF specification does not, as of the release of *sdif2ad*, require amplitudes to be within a particular range. *sdif2ad* reports information about the file to the console, including the frequency range.

The main advantages of SDIF over the *adsyn* format, for Csound users, is that SDIF files are fully portable across platforms (data is “big-endian”), and do not have the duration limit of 32.76 seconds imposed by the 16 bit *adsyn* format. This limit is necessarily imposed by *sdif2ad*. Eventually, SDIF reading will be incorporated directly into *adsyn*, thus enabling files of any length (subject to system memory limits) to be analysed and processed.

Users should remember that the SDIF formats are still under development. While the 1TRC format is now fairly well established, it can still change.

For detailed information on the Sound Description Interchange Format, refer to the CNMAT website:  
<http://cnmat.CNMAT.Berkeley.EDU/SDIF>

Some other SDIF resources (including a viewer) are available via the NC\_DREAM website: <http://www.bath.ac.uk/~masjpf/NCD/dreamhome.html>

## srconv

srconv — Converts the sample rate of an audio file.

### Description

Converts the sample rate of an audio file at sample rate Rin to a sample rate of Rout. Optionally the ratio (Rin / Rout) may be linearly time-varying according to a set of (time, ratio) pairs in an auxiliary file.

#### Note

This utility is suspect. Better is to use `libsamplerate`. `srconv` will be removed or replaced soon.

### Syntax

```
srconv [flags] infile
```

### Initialization

Flags:

- `-P num` = pitch transposition ratio (srate / r) [don't specify both P and r]
- `-Q num` = quality factor (1, 2, 3, or 4: default = 2)
- `-i filnam` = auxiliary breakpoints file (no breakpoint by default. i.e. No ratio change)
- `-r num` = output sample rate (must be specified)
- `-o fnam` = sound output filename
- `-A` = create an AIFF format output soundfile
- `-J` = create an IRCAM format output soundfile
- `-W` = create a WAV format output soundfile
- `-h` = no header on output soundfile
- `-c` = 8-bit signed\_char sound samples
- `-a` = alaw sound samples
- `-8` = 8-bit unsigned\_char sound samples
- `-u` = ulaw sound samples
- `-s` = short\_int sound samples
- `-l` = long\_int sound samples
- `-f` = float sound samples
- `-r N` = orchestra srate override

- *-K* = Do not generate PEAK chunks
- *-R* = continually rewrite header while writing soundfile (WAV/AIFF)
- *-H#* = print a heartbeat style 1, 2 or 3 at each soundfile write
- *-N* = notify (ring the bell) when score or miditrack is done
- *--fnam* = log output to file

This program performs arbitrary sample-rate conversion with high fidelity. The method is to step through the input at the desired sampling increment, and to compute the output points as appropriately weighted averages of the surrounding input points. There are two cases to consider:

1. sample rates are in a small-integer ratio - weights are obtained from table.
2. sample rates are in a large-integer ratio - weights are linearly interpolated from table.

Calculate increment: if decimating, then window is impulse response of low-pass filter with cutoff frequency at half of output sample rate; if interpolating, then window is impulse response of lowpass filter with cutoff frequency at half of input sample rate.

## Other Csound Utilities (CS, CSB64ENC, ENVEXT, EXTRACTOR, MAKECSD, MIXER, SCALE, MKDB)

The following miscellaneous utilities are available:

- *CS*: Starts Csound with a set of options that can be controlled by environment variables, and input and output files determined by the specified filename stem.
- *CSB64ENC*: Converts a binary file to a Base64 encoded text file.
- *ENVEXT*: Extract the envelope of a file to a text list.
- *EXTRACTOR*: Extract a section of audio from an audio file.
- *MAKECSD*: Creates a CSD file from the specified input files.
- *MIXER*: Mixes together a number of soundfiles.
- *SCALE*: Scale the amplitude of a sound file.
- *MKDB*: Creates a plugin opcode catalog.

## CS

cs — Starts Csound with a set of options that can be controlled by environment variables, and input and output files determined by the specified filename stem.

### Description

Starts Csound with a set of options that can be controlled by environment variables, and input and output files determined by the specified filename stem.

### Syntax

```
cs [-OPTIONS] <name> [CSOUND OPTIONS ... ]
```

### Initialization

Flags:

- - *OPTIONS* = *OPTIONS* is a sequence of alphabetic characters that can be used for selecting the Csound executable to be run, as well as the command line flags (see below). There is a default for the option 'r' (selects real-time output), but it can be overridden.
- <*name*> = this is the filename stem for selecting input files; it may contain a path. Files that have .csd, .orc, or .sco extension are searched, and either a CSD or an orc/sco pair that matches <*name*> the best are selected. MIDI files with a .mid extension are also searched, and if one that matches <*name*> at least as close as the CSD or orc/sco pair, it is used with the -F flag.

### NOTE

The MIDI file is not used if any -M or -F flag is specified by the user - new in version 4.24.0) Unless there is any option (-n or -o) related to audio output, an output file name with the appropriate extension is automatically generated (based on the name of selected input files and format options). The output file is always written to the current directory.

### NOTE

file name extensions are not case sensitive.

- [*CSOUND OPTIONS ...*] = any number of additional options for Csound that are simply copied to the final command line to be executed.

The command line that is executed is generated from four parts:

1. Csound executable (possibly with options). This is exactly one of the following (the last one has the highest precedence):
  - a built-in default
  - the value of the CSOUND environment variable
  - environment variables with a name in the format of CSOUND\_x where x is an uppercase letter se-

lected by characters of the -OPTIONS string. Thus, if the -dcba option is used, and the environment variables CSOUND\_B and CSOUND\_C are defined, the value of CSOUND\_B will take effect.

2. Any number of option lists, added in the following order:

- either some built-in defaults, or the value of the CSFLAGS environment variable if it is defined.
- environment variables with a name in the format of CSFLAGS\_x where x is an uppercase letter selected by characters of the -OPTIONS string. Thus, if the -dcba option is used, and the environment variables CSFLAGS\_A and CSFLAGS\_C are defined as '-M 1 -o dac' and '-m231 -H0', respectively, the string '-m231 -H0 -M 1 -o dac' will be added.

3. The explicit options of [CSOUND OPTIONS ... ].

4. Any options and file names generated from <name>.

## NOTE

Quoted options that contain spaces are allowed.

## Examples

Assuming the following environment variables:

```
CSOUND      = csoundfltk.exe -W
CSOUND_D    = csound64.exe -J
CSOUND_R    = csoundfltk.exe -h

CSFLAGS     = -d -m135 -H1 -s
CSFLAGS_D   = -f
CSFLAGS_R   = -m0 -H0 -o dac1 -M "MIDI Yoke NT: 1" -b 200 -B 6000
```

And a directory that contains:

```
foo.orc          piano.csd
foo.sco          piano.mid
im.csd          piano2.mid
ImproSculpt2_share.csd  foobar.csd
```

The following commands will execute as shown:

```
cs foo      => csoundfltk.exe -W -d -m135 -H1 -s -o foo.wav \
foo.orc foo.sco

cs foob      => csoundfltk.exe -W -d -m135 -H1 -s \
-o foobar.wav foobar.csd

cs -r imp -i adc => csoundfltk.exe -h -d -m135 -H1 -s -m0 -H0 \
-o dac1 -M "MIDI Yoke NT: 1" \
-b 200 -B 6000 -i adc \
ImproSculpt2_share.csd

cs -d im      => csound64.exe -J -d -m135 -H1 -s -f -o im.sf \
im.csd

cs piano      => csoundfltk.exe -W -d -m135 -H1 -s \
-F piano.mid -o piano.wav \
piano.csd

cs piano2     => csoundfltk.exe -W -d -m135 -H1 -s \
-F piano2.mid -o piano2.wav \
piano.csd
```

## csb64enc

`csb64enc` — Converts a binary file to a Base64 encoded text file.

### Description

The *csb64enc* utility generates a Base64 encoded text file from a binary file, such as a standard MIDI file (.mid) or any type of audio file. It is useful to convert a file in the format accepted by the *<CsFileB>* section of a csd file, to include the file within it.

### Syntax

```
csb64enc [OPTIONS ...] infile1 [ infile2 [ ... ]]
```

### Initialization

Flags:

- `-w n` = set line width of the output file to n (default: 72)
- `-o fname` = output file name (default: stdout)

### Examples

```
csb64enc -w 78 -o file.txt file.mid
```

This command produces a Base64 encoded text file from the standard MIDI file *file.mid*. This file can now be pasted within a csd file's *<CsFileB>* section.

## **envext**

**envext** — Extracts the envelope of a file to a text file.

### **Syntax**

```
envext [-flags] soundfile  
  
csound -U envext [-flags] soundfile
```

### **Initialization**

*soundfile* - Name of the input soundfile.

The following flags are available for envext (The default values are stated in parenthesis):

-o *fnam* Name of output filename (newenv)  
-w size (in seconds) of analysis window (0.25)

The *envext* utility generates a text file containing time and amplitude pairs by finding the absolute peak within each window.

### **Example**

Using the command (while in the manual directory):

```
csound -U envext examples/mary.wav
```

will produce the a text file containing the following:

```
0.000 0.000  
0.000 0.000  
0.250 0.000  
0.500 0.000  
0.750 0.000  
1.249 0.170  
1.499 0.269  
1.530 0.307  
1.872 0.263  
2.056 0.304  
2.294 0.241  
2.570 0.216  
2.761 0.178  
3.077 0.011  
3.251 0.001  
3.500 0.000
```

Which shows the time for the peak amplitude within each measured window.

## extractor

extractor — Extract a section of audio from an audio file.

### Description

Extract a section of audio, by time or sample, from an existing sound file.

### Syntax

```
extractor [OPTIONS ...] infile
```

### Initialization

Flags:

- *-S integer* = Start the extract at the given sample number.
- *-Z integer* = End the extract at the given sample number.
- *-Q integer* = Extract given number of samples.
- *-T fpnum* = Start the extract at the given time in seconds.
- *-E fpnum* = End the extract at the given time in seconds.
- *-D fpnum* = Extract given time in seconds.
- *-v* = Verbose mode.
- *-R* = Continually rewrite the header while writing soundfile (WAV/AIFF).
- *-H integer* = Show a "heart-beat" to indicate progress, in style 1, 2 or 3.
- *-N* = Alert call (usually ringing the bell) when finished.
- *-v* = Verbose mode.
- *-o fname* = output file name (default: test.wav)

### Examples

The default values are

```
extractor -S 0 -Z end-of-file -otest
```

For example

```
extractor -S 10234 -D 2.13 in.aiff -o out.wav
```

This creates a new sound file taken from sample 10234 and lasting 2.13 seconds.

## makecsd

makecsd — Creates a CSD file from the specified input files.

### Description

Creates a CSD file from the specified input files. The first input file that has a .orc extension (case is not significant) is put to the <CsInstruments> section, and the first input file that has a .sco extension becomes <CsScore>. Any remaining files are Base64 encoded and added as <CsFileB> tags. An empty <CsOptions> section is always added.

Some text filtering is performed on the orchestra and score file:

- newlines are converted to the native format of the system on which makecsd is being run.
- blank lines are removed from the beginning and end of files.
- any trailing whitespace is removed from the end of lines.
- optionally, tabs can be expanded to spaces with an user specified tabstop size.
- optionally, a MIDI file can be included.
- optionally, a Licence can be specified as either a file or a common one.
- if required a score processor can be specified for the <CsScore> section.

### Syntax

```
makecsd [OPTIONS ...] infile1 [ infile2 [ ... ]]
```

### Initialization

Flags:

- *-t n* = expand tabs to spaces using tabstop size n (default: disabled). This applies only to the orchestra and score file.
- *-w n* = set Base64 line width to n (default: 72). Note: the orchestra and score are not wrapped.
- *-o fname* = output file name (default: stdout)
- *-m fname* = specify a MIDI file to include (default: none)
- *-b progrname* = specify the program to process the score (default: none)
- *-L fname* = file name containing the licence text (default: none)
- *-l integer* = specify a standard licence (default: none). The ones available are:
  - 0: All rights reserved
  - 1: CC BY-NC-ND

- 2: CC BY-NC-SA
- 3: CC BY-NC
- 4: CC BY-ND
- 5: CC BY-SA
- 6: CC BY
- 7: Licenced under BSD

## Examples

```
makecsd -t 6 -w 78 -o file.cs file.mid file.orc file.sco sample.aif
```

This creates a CSD from file.orc and file.sco (tabs are expanded to spaces assuming a tabstop size of 6 characters), and file.mid and sample.aif are added as <CsFileB> tags containing Base64 encoded data with a line width of 78 characters. The output file is file.cs.

## mixer

**mixer** — Mixes together a number of soundfiles.

### Description

Mixes together a number of soundfiles, starting at different times and with individual channel selection from the input files.

### Syntax

```
mixer [OPTIONS ... ] infile [[OPTIONS... ] infile] ...
```

### Initialization

Flags:

- **-A** = Generate an AIFF output file.
- **-W** = Generate an WAV output file.
- **-h** = Generate an output file with no header.
- **-c** = Generate 8-bit signed\_char sound samples.
- **-a** = Generate alaw sound samples.
- **-u** = Generate ulaw sound samples.
- **-s** = Generate short integer sound samples.
- **-l** = Generate long (32 bit) integer sound samples.
- **-f** = Generate floating point samples.
- **-F arg** = Specifies the gain to be applied to the following input file. If arg is a floating point number that gain is applied uniformly to the input. Alternatively it could be a file name which specifies a breakpoint file for varying the gain for different periods.
- **-S integer** = Indicate at which sample to start to mix in the next input file.
- **-T fpnum** = Indicate at which time (in seconds) to start to mix in the next input file.
- **-I** = Mix in channel 1 from next sound file.
- **-2** = Mix in channel 2 from next sound file.
- **-3** = Mix in channel 3 from next sound file.
- **-4** = Mix in channel 4 from next sound file.
- **-^ intx inty** = Mix in channel x from next sound file as channel y in the output.
- **-v** = Verbose mode.
- **-R** = Continually rewrite the header while writing soundfile (WAV/AIFF).

- *-H integer* = Show a "heart-beat" to indicate progress, in style 1, 2 or 3.
- *-N* = Alert call (usually ringing the bell) when finished.
- *-o fname* = output file name (default: test.wav)

## Examples

The default values are

```
mixer -s -otest -F 1.0 -S 0
```

For example

```
mixer -F 0.96 in1.wav -S 300 -2 in2.aiff -S 300 -^4 1 in3.wav -o out.wav
```

This creates a new sound file with a constant gain of 0.96 from in1.wav with the second channel of in2.aiff mixed in after 300 samples and channel 4 of in3.wav output as channel 1 after 300 samples.

## scale

scale — Scale the amplitude of a sound file.

### Description

Takes a sound file and scales it by applying a gain, either constant or variable. The scale can be specified as a multiplier, a maximum or a percentage of 0db.

### Syntax

```
scale [OPTIONS ...] infile
```

### Initialization

Flags:

- **-A** = Generate an AIFF outout file.
- **-W** = Generate an WAV outout file.
- **-h** = Generate an outout file with no header.
- **-c** = Generate 8-bit signed\_char sound samples.
- **-a** = Generate alaw sound samples.
- **-u** = Generate ulaw sound samples.
- **-s** = Generate short integer sound samples.
- **-l** = Generate long (32 bit) integer sound samples.
- **-f** = Generate floating point samples.
- **-F arg** = Specifies the gain to be applied. If arg is a floating point number that gain is applied uniformly to the input. Alternatively it could be a file name which specifies a breakpoint file for varying the gain for different periods.
- **-M fpnum** = Scales the input so the maximum absolute displacement is the value given.
- **-P fpnum** = Scales the input so the maximum absolute displacement is the percentage given of 0db.
- **-R** = Continually rewrite the header while writing soundfile (WAV/AIFF).
- **-H integer** = Show a "heart-beat" to indicate progress, in style 1, 2 or 3.
- **-N** = Alert call (usually ringing the bell) when finished.
- **-o fname** = output file name (default: test.wav)

### Examples

```
scale -s -w -F 0.96 -o out.wav sound.wav
```

This creates a new sound file with a constant gain of 0.96. It is particularly useful if the input file is in floating point format.

## **mkdb**

**mkdb** — Outputs a catalog of opcodes and plugin modules.

### **Description**

Outputs a catalog of opcodes and plugin modules, sorted by opcode name or by module.

### **Syntax**

```
mkdb [-m] [base_directory]
```

### **Credits**

# Cscore

*Cscore* is an API (application programming interface) for generating and manipulating numeric score files. It is a part of the larger Csound API and includes a number of functions that can be called by a user-designed program written in the C language. *Cscore* can be invoked either as a standalone score preprocessor, or as part of a Csound performance by including the -C flag in its arguments:

```
cscore [scorefilein] [> scorefileout]
```

(where *cscore* is the name of your user-written program), or

```
csound [-C] [otherflags] [orchname] [scorename]
```

The available API functions augment the C language library functions; they can read either standard numeric scores or pre-sorted score files, can massage and expand the data in various ways, then make it available for performance by a Csound orchestra.

The user-written control program is written in C, and is compiled and linked to the Csound library (or the csound commandline program) by the user. It is not essential to know the C language well to write this program, since the function calls have a simple syntax, and are powerful enough to do most of the complicated work. Additional power can come from C later as the need arises.

The following sections explain all of the steps needed to make use of *Cscore*:

- *Events, Lists, and Operations* - Explains the syntax of *Cscore* functions and data structures.
- *Writing a Cscore Control Program* - Illustrates by example how to write your own control program.
- *Compiling a Cscore Program* - Outlines the steps for compiling and linking with the Csound library.
- *More Advanced Examples* - Addresses advanced issues such as multiple input scores and the details of running *Cscore* inside of a Csound performance.

## Events, Lists, and Operations

An event in *Cscore* is equivalent to one statement of a *standard numeric score* or a time-warped score (the format in which Csound writes a sorted score -- see any score.srt), and is stored internally in time-warped format. It is important to note that when *Cscore* is used in standalone-mode, it cannot understand any of the non-numeric "conveniences" that Csound allows in the input score format. Therefore, scores making use of features such as carry, ramp, expressions, and others will have to either be sorted first with the *scsort* utility or used with a modified *Csound* executable that contains the user's *Cscore* program. Score opcodes with macro arguments (r, m, n, and {}) are not understood.

Score events are each read in from an existing score file and stored in a C structure. The structures main components are an opcode and an array of pfield values. *Cscore* handles reading the events and storing them in memory for you. The format of the structure starts as

follows:

```
typedef struct {
    CSHDR h;          /* space-managing header */
    char *strarg;    /* address of optional string argument */
    char op;          /* opcode-t, w, f, i, a, s or e */
    short pcnt;
    MYFLT p2orig;   /* unwarped p2, p3 */
    MYFLT p3orig;
    MYFLT p[1];      /* array of pfields p0, p1, p2 ... */
} EVENT;
```

MYFLT is either the C type *float* or *double* depending on how your copy of the Csound library was compiled. You should just declare any floating-point variables as MYFLT in your user program for compatibility.

Any *Cscore* function that creates, reads, or copies an event will return a pointer to the storage structure holding the event data. The event pointer can be used to access any component of the structure, in the form of *e->op* or *e->p[n]*. Each newly stored event will give rise to a new pointer, and a sequence of new events will generate a sequence of distinct pointers that must themselves be stored. Groups of event pointers are stored in an event list, which has its own structure:

```
typedef struct {
    CSHDR h;
    int nslots;     /* max events in this event list */
    int nevents;    /* number of events present */
    EVENT *e[1];    /* array of event pointers e0, e1, e2... */
} EVLIST;
```

Any *Cscore* function that creates or modifies a list will return a pointer to the new list. The list pointer can be used to access any of its component event pointers, in the form of *a->e[n]*. Event pointers and list pointers are thus primary tools for manipulating the data of a score file. Pointers and lists of pointers can be copied and reordered without modifying the data values they refer to. This means that notes and phrases can be copied and manipulated from a high level of control. Alternatively, the data within an event or group of events can be modified without changing the event or list pointers. The *Cscore* API functions enable scores to be created and manipulated in this way.

With Csound 5, the names of all of the *Cscore* API functions have changed to be more explicit. In addition, each function now requires a pointer to a CSOUND object as its first argument. The structure of the CSOUND object is unimportant (and indeed cannot be modified in a user program). How to obtain this CSOUND pointer will be shown in the next section. The *Cscore* functions and data structures are available in the *cscore.h* header file, which you must include in your program code before you can use them.

The names of the *Cscore* functions specify whether they operate on single events or event lists. In the following summary of available function calls, some simple naming conventions are used:

```
The symbol cs is a pointer to a CSOUND object (CSOUND *);
The symbols e, f are pointers to events (notes);
The symbols a, b are pointers to lists (arrays) of such events;
The symbol n is an integer parameter of type int;
"..." indicates a string parameter (either a constant or variable of type char *);
The symbol fp is a score input stream file pointer (FILE *);
```

calling syntax

description

```

-----
/* Functions for working with single events */
e = cscoreCreateEvent(cs, n);           create a blank event with n pfields
e = cscoreDefineEvent(cs, "...");      defines an event as per the character string ...
e = cscoreCopyEvent(cs, f);            make a new copy of event f
e = cscoreGetEvent(cs);                read the next event in the score input file
e = cscorePutEvent(cs, e);             write event e to the score output file
e = cscorePutString(cs, "...");       write the string-defined event to score output

-----
```

```

/* Functions for working with event lists */
a = cscoreListCreate(cs, n);           create an empty event list with n slots
a = cscoreListAppendEvent(cs, a, e);   append event e to list a
a = cscoreListAppendStringEvent(cs, a, "..."); append a string-defined event to list a;
a = cscoreListCopy(cs, b);            copy the list b (but not the events)
a = cscoreListCopyEvents(cs, b);     copy the events of b, making a new list
a = cscoreListGetSection(cs);        read all events from score input, up to next s or e
a = cscoreListGetNext(cs, nbeats);    read next nbeats beats from score input (nbeats is MYF)
a = cscoreListGetUntil(cs, beatno);  read all events from score input up to beat beatno (MYF)
a = cscoreListSeparateF(cs, b);     separate the f statements from list b into list a
a = cscoreListSeparateTWF(cs, b);   separate the t,w & f statements from list b into list a
a = cscoreListAppendList(cs, a, b);  separate the t,w & f statements from list b into list a
a = cscoreListConcatenate(cs, a, b); append the list b onto the list a
a = cscoreListSort(cs, a);          concatenate (append) the list b onto the list a (same a
n = cscoreListCount(cs, a);         sort the list a into chronological order by p[2]
a = cscoreListExtractInstruments(cs, b, "..."); returns the number of events in list a
a = cscoreListExtractTime(cs, b, from, to); extract notes of instruments ... (no new events)
a = cscoreListPut(cs, a);           extract notes of time-span, creating new events (from a
a = cscoreListPlay(cs, a);         write the events of list a to the score output file
                                 send events of list a to the Csound orchestra for
                                 immediate performance (or print events if no orchestra)

-----
```

```

/* Functions for reclaiming memory */
cscoreFreeEvent(cs, e);              release the space of event e
cscoreListFree(cs, a);               release the space of list a (but not the events)
cscoreListFreeEvents(cs, a);         release the events of list a, and the list space

-----
```

```

/* Functions for working with multiple input score files */
fp = cscoreFileGetCurrent(cs);       get the currently active input scorefile pointer
fp = cscoreFileOpen(cs, "filename"); (initially finds the command-line input scorefile pointer)
fp = cscoreFileSetCurrent(cs, fp);   open another input scorefile (maximum of 5)
fp = cscoreFileClose(cs, fp);       make fp the currently active scorefile pointer
                                    close the scorefile relating to FILE *fp

```

Under Csound 4, the function names and parameters were as follows:

| calling syntax                             | description   |
|--|---|
| e = createn(n);                            | create a blank event with n pfields                     |
| e = defev("...");                          | defines an event as per the character string ...        |
| e = copyev(f);                             | make a new copy of event f                              |
| e = getev();                               | read the next event in the score input file             |
| putev(e);                                  | write event e to the score output file                  |
| putstr("...");                             | write the string-defined event to score output          |
| a = lcreat(n);<br>int n;                   | create an empty event list with n slots                 |
| a = lappiev(a,e);                          | append event e to list a                                |
| a = lappstrev(a,"...");                    | append a string-defined event to list a;                |
| a = lcopy(b);                              | copy the list b (but not the events)                    |
| a = lcopyev(b);                            | copy the events of b, making a new list                 |
| a = lget();                                | read all events from score input, up to next s or e     |
| a = lgetnext(nbeats);<br>float nbeats;     | read next nbeats beats from score input                 |
| a = lgetuntil(beatno);<br>float beatno;    | read all events from score input up to beat beatno      |
| a = lsepf(b);                              | separate the f statements from list b into list a       |
| a = lseptwf(b);                            | separate the t,w & f statements from list b into list a |
| a = lcat(a,b);                             | concatenate (append) the list b onto the list a         |
| lsort(a);                                  | sort the list a into chronological order by p[2]        |
| a = lxins(b,"...");                        | extract notes of instruments ... (no new events)        |
| a = lxtimev(b,from,to);<br>float from, to; | extract notes of time-span, creating new events         |
| lput(a);                                   | write the events of list a to the score output file     |
| lplay(a);                                  | send events of list a to the Csound orchestra for       |
| relev(e);                                  | immediate performance (or print events if no orchestra) |
|  | release the space of event e                            |

```
lrel(a);           release the space of list a (but not the events)
lrelev(a);        release the events of list a, and the list space
fp = getcurfp();   get the currently active input scorefile pointer
                   (initially finds the command-line input scorefile pointer)
fp = filopen("filename"); open another input scorefile (maximum of 5)
setcurfp(fp);     make fp the currently active scorefile pointer
filclose(fp);     close the scorefile relating to FILE *fp
```

## Writing a Cscore Control Program

The general format for a *Cscore* control program is:

```
#include "cscore.h"
void cscore(CSOUND *cs)
{
    /* VARIABLE DECLARATIONS */
    /* PROGRAM BODY */
}
```

The *include* statement will define the event and list structures and all of the *Cscore* API functions for the program. The name of the user function needs to be *cscore* if it will be linked with the standard main program in *cscormai.c* or linked as the internal *Cscore* routine for a personal Csound executable. This *cscore()* function receives one argument from *cscormai.c* or Csound -- *CSOUND \*cs* -- which is a pointer to a Csound object. The pointer *cs* must be passed as the first parameter to every *Cscore* API function that the program calls.

The following C program will read from a *standard numeric score*, up to (but not including) the first *s* or *e* *statement*, then write that data (unaltered) as output.

```
#include "cscore.h"
void cscore(CSOUND *cs)
{
    EVLIST *a;           /* a is allowed to point to an event list */
    a = cscoreListGetSection(cs); /* read events in, return the list pointer */
    cscoreListPut(cs, a);    /* write these events out (unchanged) */
    cscorePutString(cs, "e"); /* write the string e to output */
}
```

After execution of *cscoreListGetSection()*, the variable *a* points to a list of event addresses, each of which points to a stored event. We have used that same pointer to enable another list function -- *cscoreListPut()* -- to access and write out all of the events that were read. If we now define another symbol *e* to be an event pointer, then the statement

```
e = a->e[4];
```

will set it to the contents of the 4th slot in the *EVLIST* structure, *a*. The contents is a pointer to an event, which is itself comprised of an *array* of parameter field values. Thus the term *e->p[5]* will mean the value of parameter field 5 of the 4th event in the *EVLIST* denoted by *a*. The program below will multiply the value of that *pfield* by 2 before writing it out.

```
#include "cscore.h"
void cscore(CSOUND *cs)
{
    EVENT *e;           /* a pointer to an event */
    EVLIST *a;
    a = cscoreListGetSection(cs); /* read a score as a list of events */
    e = a->e[4];        /* point to event 4 in event list a */
    e->p[5] *= 2;        /* find pfield 5, multiply its value by 2 */
    cscoreListPut(cs, a); /* write out the list of events */
    cscorePutString(cs, "e"); /* add a "score end" statement */
}
```

Now consider the following score, in which *p*[5] contains frequency in Hz.

```
f 1 0 257 10 1
f 2 0 257 7 0 300 1 212 .8
i 1 1 3 0 440 10000
i 1 4 3 0 256 10000
i 1 7 3 0 880 10000
e
```

If this score were given to the preceding main program, the resulting output would look like this:

```
f 1 0 257 10 1
f 2 0 257 7 0 300 1 212 .8
i 1 1 3 0 440 10000
i 1 4 3 0 512 10000      ; p[5] has become 512 instead of 256.
i 1 7 3 0 880 10000
e
```

Note that the 4th event is in fact the second note of the score. So far we have not distinguished between notes and function table setup in a numeric score. Both can be classed as events. Also note that our 4th event has been stored in *e*[4] of the structure. For compatibility with Csound *pfield* notation, we will ignore *p*[0] and *e*[0] of the event and list structures, storing *p*1 in *p*[1], event 1 in *e*[1], etc. The *Cscore* functions all adopt this convention.

As an extension to the above, we could decide to use the same pointers *a* and *e* to examine each of the events in the list. Note that *e* was not set to the numeral 4, but to the location of the 4th slot in the list. To inspect *p*5 of the previous event in the list, we need only redefine *e* with the assignment

```
e = a->e[3];
```

and reference the 5th slot of the *pfield* array using the expression

```
e->p[5]
```

More generally, we can use an integer variable as an index to the array *e*[*J*], and access each event in sequence by using a loop and incrementing the index. The number of events stored in an *EVLIST* is contained in the *nevents* member of the struct.

```
int index; /* start with e[1] because e[0] is not used */
```

```
for (index = 1; index <= a->nevents; index++)
{
    e = a->e[index];
    /* do something with e */
}
```

The above example starts with *e[1]* and increases the index each time through the loop (*index++*) until it is greater than *a->nevents*, the index of the last event in the list. The statements inside the *for* loop do execute a final time when *index* equals *a->nevents*.

In the following program we will use the same input score. This time we will separate the *ftable* statements from the *note* statements. We will next write the three note-events stored in the list *a* to the output, then create a second score section consisting of the original pitch set and a transposed version of itself. This will bring about an octave doubling.

Here, our index to the array is *n* and we increment *n* as part of a *for* block which iterates *nevents* times, allowing one statement to act upon the same *pfield* of each successive event.

```
#include "cscore.h"
void cscore(CSOUND *cs)
{
    EVENT   *e, *f;
    EVLIST *a, *b;
    int n;

    a = cscoreListGetSection(cs);
    b = cscoreListSeparateF(cs, a);
    cscoreListPut(cs, b);
    cscoreListFreeEvents(cs, b);
    e = cscoreDefineEvent(cs, "t 0 120");
    cscorePutEvent(cs, e);
    cscoreListPut(cs, a);
    cscorePutString(cs, "s");
    cscorePutEvent(cs, e);
    b = cscoreListCopyEvents(cs, a);
    for (n = 1; n <= b->nevents; n++)
    {
        f = b->e[n];
        f->p[5] *= 0.5;
    }
    a = cscoreListAppendList(cs, a, b);
    cscoreListPut(cs, a);
    cscorePutString(cs, "e");
}
```

The output of this program is:

```
f 1 0 257 10 1
f 2 0 257 7 0 300 1 212 .8
t 0 120
i 1 1 3 0 440 10000
i 1 4 3 0 256 10000
i 1 7 3 0 880 10000
s
t 0 120
i 1 1 3 0 440 10000
i 1 4 3 0 256 10000
i 1 7 3 0 880 10000
i 1 1 3 0 220 10000
i 1 4 3 0 128 10000
i 1 7 3 0 440 10000
e
```

If the output is only being written to a file, then the unsorted order of the events is not a problem. The output is written to a file (or standard output) whenever the function `cscoreListPut()` is used. However, if this program were to be called during a Csound performance and the function `cscoreListPlay()` replaced `cscoreListPut()`, then the events would be sent to the orchestra instead of to a file and they should then be sorted beforehand by calling the function `cscoreListSort()`. The details of score output and playing when using *Cscore* from within Csound are described in the next section.

Next we extend the above program by using the `for` loop to look at  $p[5]$  and  $p[6]$ . In the original score  $p[6]$  denotes amplitude. To create a diminuendo in the added lower octave, which is independent from the original set of notes, a variable called *dim* will be used.

```
#include "cscore.h"
void cscore(CSOUND *cs)
{
    EVENT  *e, *f;
    EVLIST *a, *b;
    int n, dim;                                /* declare two integer variables */

    a = cscoreListGetSection(cs);
    b = cscoreListSeparateF(cs, a);
    cscoreListPut(cs, b);
    cscoreListFreeEvents(cs, b);
    e = cscoreDefineEvent(cs, "t 0 120");
    cscorePutEvent(cs, e);
    cscoreListPut(cs, a);
    cscorePutString(cs, "s");
    cscorePutEvent(cs, e);                      /* write out another tempo statement */
    b = cscoreListCopyEvents(cs, a);
    dim = 0;                                    /* initialize dim to 0 */
    for (n = 1; n <= b->nevents; n++)
    {
        f = b->e[n];
        f->p[6] -= dim;                         /* subtract current value of dim */
        f->p[5] *= 0.5;                          /* transpose pitch down one octave */
        dim += 2000;                             /* increase dim for each note */
    }
    a = cscoreListAppendList(cs, a, b);          /* now add these notes to original pitches */
    cscoreListPut(cs, a);
    cscorePutString(cs, "e");
}
```

Using the same input score again, the output from this program is:

```
f 1 0 257 10 1
f 2 0 257 7 0 300 1 212 .8
t 0 120
i 1 1 3 0 440 10000
i 1 4 3 0 256 10000
i 1 7 3 0 880 10000
s
t 0 120
i 1 1 3 0 440 10000 ; Three original notes at
i 1 4 3 0 256 10000 ; beats 1,4 and 7 with no dim.
i 1 7 3 0 880 10000
i 1 1 3 0 220 10000 ; three notes transposed down one octave
i 1 4 3 0 128 8000 ; also at beats 1,4 and 7 with dim.
i 1 7 3 0 440 6000
e
```

In the following program the same three-note sequence will be repeated at various time intervals. The starting time of each group is determined by the values of the array *cue*. This time the *dim* will occur for each group of notes rather than each note. Note the position of the statement which increments the variable *dim* outside the inner `for` loop.

```
#include "cscore.h"
int cue[3] = {0,10,17};
void cscore(CSOUND *cs)
{
    EVENT *e, *f;
    EVLIST *a, *b;
    int n, dim, cuecount;
/* declare an array of 3 integers */

    a = cscoreListGetSection(cs);
    b = cscoreListSeparateF(cs, a);
    cscoreListPut(cs, b);
    cscoreListFreeEvents(cs, b);
    e = cscoreDefineEvent(cs, "t 0 120");
    cscorePutEvent(cs, e);
    dim = 0;
    for (cuecount = 0; cuecount <= 2; cuecount++) /* elements of cue are numbered 0, 1, 2 */
    {
        for (n = 1; n <= a->nevents; n++)
        {
            f = a->e[n];
            f->p[6] -= dim;
            f->p[2] += cue[cuecount]; /* add values of cue */
        }
        printf("; diagnostic: cue = %d\n", cue[cuecount]);
        dim += 2000;
        cscoreListPut(cs, a);
    }
    cscorePutString(cs, "e");
}
```

Here the inner *for* loop looks at the events of list *a* (the notes) and the outer *for* loop looks at each *repetition* of the events of list *a* (the pitch group "cues"). This program also demonstrates a useful troubleshooting device with the *printf* function. The *semi-colon* is first in the character string to produce a comment statement in the resulting score file. In this case the value of *cue* is being printed in the output to insure that the program is taking the proper *array* member at the proper time. When output data is wrong or error messages are encountered, the *printf* function can help to pinpoint the problem.

Using the same input file, the C program above will generate the following score. Can you determine why the last set of notes starts at the wrong time and how to correct the problem?

```
f 1 0 257 10 1
f 2 0 257 7 0 300 1 212 .8
t 0 120
; diagnostic: cue = 0
i 1 1 3 0 440 10000
i 1 4 3 0 256 10000
i 1 7 3 0 880 10000
; diagnostic: cue = 10
i 1 11 3 0 440 8000
i 1 14 3 0 256 8000
i 1 17 3 0 880 8000
; diagnostic: cue = 17
i 1 28 3 0 440 4000
i 1 31 3 0 256 4000
i 1 34 3 0 880 4000
e
```

## Compiling a Cscore Program

A *Cscore* program can be invoked either as a *standalone program* or as part of *Csound* in between sorting the score and performing the score with the orchestra:

```
cscore [scorefilein] [> scorefileout]
```

or

```
csound [-C] [otherflags] [orchname] [scorename]
```

Before trying to compile your own *Cscore* program, you will most likely want to obtain a copy of the Csound source code. Either download the latest source distribution for your platform or check out a copy of the csound5 module from Sourceforge CVS. There are several files in the sources that will help you. Within the `examples/cscore/` directory are a number of examples of *Cscore* control programs, including all of the examples contained in this manual. And in the `frontends/cscore/` directory are the two files `cscoremain.c` and `cscore.c`. `cscoremain.c` contains a simple *main* function that performs all of the initialization that a standalone *Cscore* program needs to do before it calls your control function. This main “stub” initializes Csound, reads the commandline arguments, opens the input and output score files, and then calls a function `cscore()`. As described above, it is expected that you will write the `cscore()` function and provide it in another file. The file `frontends/cscore/csccore.c` shows the simplest example of a `cscore()` function that reads in a score of any length and writes it to the output unchanged.

So, to create a standalone program, write a control program as shown in the previous section. Let's assume that you saved this program in a file named “`mycscore.c`”. Next, you need to compile and link this program with the Csound library and `cscoremain.c` in order to create an executable by following the set of directions below that apply to your operating system. It will be helpful to already have some familiarity with the C compiler on your computer since the information below cannot be complete for all possible systems.

## Linux and Unix

The following commands assume that you have copied your file `mycscore.c` into the same directory as `cscoremain.c`, that you have opened a terminal to that same directory, and that you have previously installed a binary distribution of Csound that placed a library `libcsound.a` or `libcsound.so` into `/usr/local/lib` and the header files for the Csound API into `/usr/local/include/csound`.

To compile and link:

```
gcc mycscore.c cscoremain.c -o cscore -lcsound -L/usr/local/lib -I/usr/local/include/csound
```

To run (sending the results to standard output):

```
./cscore test.sco
```

It is possible that on some Unix systems, the C compiler will be named `cc` or something else other than `gcc`.

## Windows

Csound is usually compiled on Windows using the MinGW environment that makes GCC -- the same compiler used on Linux -- available using a Unix-like command shell (MSYS). Since pre-compiled libraries for Csound on Windows are built in this way, you may need to use MinGW as well to link to them. If you have built Csound using another compiler, then you should be able to build *Cscore* with that compiler as well.

Compiling standalone *Cscore* programs using MinGW should be similar to the procedure for Linux above with library and header paths changed appropriately for where Csound is installed on the Windows system. (*Please feel free to contribute more detailed instructions here as the editor has been unable to test Cscore on a Windows machine*).

## OS X

The following commands assume that you have copied your file *myscore.c* into the same directory as *cscoremaint.c* and that you have opened a terminal to that same directory. In addition, the Apple-supplied developer tools (including the GCC compiler) should be installed on your system and you should have previously installed a binary distribution of Csound that placed the CsoundLib framework into */Library/Frameworks*.

Use this command compile and link. (You may get a warning about "multiple definitions of symbol *\_cscore*").

```
gcc cscore.c cscoremaint.c -o cscore -framework CsoundLib -I/Library/Frameworks/CsoundLib.framework/Hea
```

To run (sending the results to standard output):

```
./cscore test.sco
```

## MacOS 9

You will need CodeWarrior or some other development environment installed on your computer (MPW may work). Download the source code distribution for OS 9 (it will have a name like *Csound5.05\_OS9\_src.smi.bin*).

If using CodeWarrior, find and open the project file "Cscore5.cw8.mcp" in the folder "Csound5.04-OS9-source:macintosh:Csound5Library:". This project file is configured to use the source files *cscore.c* and *cscoremaint\_MacOS9.c* from the csound5 source tree and the Csound5Lib shared library produced by compiling Csound with the "Csound5.cw8.mcp" project file. You should substitute your own *Cscore* program file for *cscore.c* and either compile Csound5Lib first or substitute a copy of the library in the project from the binary distribution of Csound for OS 9. The file *cscoremaint\_MacOS9.c* contains specialized code for configuring CodeWarrior's SIOUX console library and allows commandline arguments to be entered before the program is run.

Once you have the proper files included in the project window, click the "Make" button and CodeWarrior should produce an application named "*Cscore*". When you run this application, it first displays a window allowing you to type in the arguments to the main function. You only need to type in the filename or pathname to the input score -- do not type in "cscore". The input file should be in the same folder as the application or else you will need to type a full or relative pathname to the file. Output will be displayed in the console window. You can use the *Save* command from the *File* menu before quitting if you wish. Alternatively, in the commandline dialog, you can choose to redirect the output to a file by clicking on the *File* button on the right side of the dialog. (Note that the console window can only display about 32,000 characters, so writing to a file is necessary for long scores).

## Making Cscore usable from within Csound

To operate from Csound, first follow the instructions for compiling Csound (see *Building Csound*) according to the operating system that you are using. Once you have successfully built an unmodified

Csound system, then substitute your own *cscore()* function for the one in the file *Top/cscore\_internal.c*, and rebuild Csound.

The resulting executable is your own special Csound, usable as above. The *-C flag* will invoke your *Cscore* program after the input score is sorted into “*score.srt*”. The details of what happens when you run Csound with the *-C* flag are given in the next section.

Csound 5 also provides an additional way to run your own *Cscore* program from within Csound. Using the API, a host application can set a *Cscore callback function*, which is a function that Csound will call instead of using the built-in *cscore()* function. One advantage of this approach is that it is not necessary to recompile the entirety of Csound. Another benefit is that the host application can select at runtime from more than one *Cscore* function to designate as the callback. The disadvantage is that you need to write a host application.

A simple approach to using a *Cscore* callback via the API would be to modify the standard Csound main program -- which is a simple Csound host -- contained in the file *frontends/csound/csound\_main.c*. Adding a call to *csoundSetCscoreCallback()* after the call to *csoundCreate()* but before the call to *csoundCompile()* should do the job. Recompiling this file and linking to an existing Csound library will make a commandline version of Csound that works similarly to the one described above. Don't forget to use the *-C* flag.

## Notes about score formats and run-time behavior

As stated previously, the input files to *Cscore* may be in original or time-warped and pre-sorted form; this modality will be preserved (section by section) in reading, processing, and writing scores. Standalone processing will most often use unwarped sources and create unwarped new files. When running from within Csound, the input score will arrive already warped and sorted, and can thus be sent directly (normally section by section) to the orchestra. One advantage of this method of using *Cscore* is that all of the syntactical conveniences of the full Csound score language may be used -- macros, arithmetic expressions, carry, ramp, etc. -- since the score will go through the "Carry, Tempo, Sort" phases of score processing before being passed to the user-supplied *Cscore* program.

When running within Csound, a list of events can be conveyed to a Csound orchestra using *cscoreListPlay()*. There may be any number of *cscoreListPlay()* calls in a *Cscore* program. Each list so conveyed can be either time-warped or not, but each list must be in strict *p2*-chronological order (either from pre-sorting or using *cscoreListSort()*). If there is no *cscoreListPlay()* in a *Cscore* module run from within Csound, all events written out (via *cscorePutEvent()*, *cscorePutString()*, or *cscoreListPut()*) are written to a new score in the current directory with the name “*cscore.out*”. Csound then invokes the score sorter again before sending this new score to the orchestra for performance. The final, sorted, output score is written to a file named “*cscore.srt*”.

A standalone *Cscore* program will normally use the “put” commands to write into its output file. If a standalone *Cscore* program calls *cscoreListPlay()*, the events thus intended for performance will be sent to the output in the same way as if *cscoreListPut()* had been called instead.

A note list sent by *cscoreListPlay()* for performance should be temporally distinct from subsequent note lists. No note-end should extend past the next list's start time, since *cscoreListPlay()* will complete each list before starting the next (i.e. like a Section marker that doesn't reset local time to zero). This is important when using *cscoreListGetNext()* or *cscoreListGetUntil()* to fetch and process score segments prior to performance, because these functions may only read part of an unsorted section.

## More Advanced Examples

The following program demonstrates reading from two different input files. The idea is to switch between two 2-section scores, and write out the interleaved sections to a single output file.

```
#include "cscore.h"                                /* CSCORE_SWITCH.C */
cscore(CSOUND* cs)                                /* callable from either Csound or standalone cscore */
{
    EVLIST *a, *b;
    FILE *fp1, *fp2;                                /* declare two scorefile stream pointers */
    fp1 = cscoreFileGetCurrent(cs);                 /* this is the command-line score */
    fp2 = cscoreFileOpen(cs, "score2.srt");          /* this is an additional score file */
    a = cscoreListGetSection(cs);                   /* read section from score 1 */
    cscoreListPut(cs, a);                           /* write it out as is */
    cscorePutString(cs, "s");
    cscoreFileSetCurrent(cs, fp2);
    b = cscoreListGetSection(cs);                   /* read section from score 2 */
    cscoreListPut(cs, b);                           /* write it out as is */
    cscorePutString(cs, "s");
    cscoreListFreeEvents(cs, a);                   /* optional to reclaim space */
    cscoreListFreeEvents(cs, b);
    cscoreFileSetCurrent(cs, fp1);
    a = cscoreListGetSection(cs);                   /* read next section from score 1 */
    cscoreListPut(cs, a);                           /* write it out */
    cscorePutString(cs, "s");
    cscoreFileSetCurrent(cs, fp2);
    b = cscoreListGetSection(cs);                   /* read next sect from score 2 */
    cscoreListPut(cs, b);                           /* write it out */
    cscorePutString(cs, "e");
}
```

Finally, we show how to take a literal, uninterpreted score file and imbue it with some expressive timing changes. The theory of composer-related metric pulses has been investigated at length by Manfred Clynes, and the following is in the spirit of his work. The strategy here is to first create an *array* of new *onset* times for every possible sixteenth-note onset, then to index into it so as to adjust the start and duration of each note of the input score to the interpreted time-points. This also shows how a Csound orchestra can be invoked repeatedly from a run-time score generator.

```
#include "cscore.h"                                /* CSCORE_PULSE.C */
/* program to apply interpretive durational pulse to      */
/* an existing score in 3/4 time, first beats on 0, 3, 6 ... */

static float four[4] = { 1.05, 0.97, 1.03, 0.95 };    /* pulse width for 4's */
static float three[3] = { 1.03, 1.05, .92 };           /* pulse width for 3's */

cscore(CSOUND* cs)                                /* This example should be called from Csound */
{
    EVLIST *a, *b;
    EVENT *e, **ep;
    float pulse16[4*4*4*4*3*4];      /* 16th-note array, 3/4 time, 256 measures */
    float acc16, acc1, inc1, acc3, inc3, acc12, inc12, acc48, inc48, acc192, inc192;
    float *p = pulse16;
    int n16, n1, n3, n12, n48, n192;

    /* fill the array with interpreted ontimes */
    for (acc192=0., n192=0; n192<4; acc192+=192.*inc192, n192++)
        for (acc48=acc192, inc48=four[n192], n48=0; n48<4; acc48+=48.*inc48, n48++)
            for (acc12=acc48, inc12=inc192*four[n48], n12=0; n12<4; acc12+=12.*inc12, n12++)
                for (acc3=acc12, inc3=inc12*four[n12], n3=0; n3<4; acc3+=3.*inc3, n3++)
                    for (acc1=acc3, inc1=inc3*four[n3], n1=0; n1<3; acc1+=inc1, n1++)
                        for (acc16=acc1, inc1=inc1*three[n1], n16=0; n16<4; acc16+=.25*inc1*four[n16], n16++)
                            *p++ = acc16;

    /* for (p = pulse16, n1 = 48; n1--; p += 4) /* show vals & diffs */
    /*     printf("%g %g %g %g %g %g %g\n", *p, *(p+1), *(p+2), *(p+3),
    /*            *(p+1)-*p, *(p+2)-*(p+1), *(p+3)-*(p+2), *(p+4)-*(p+3)); */

    a = cscoreListGetSection(cs);                      /* read sect from tempo-warped score */
    b = cscoreListSeparateTWF(cs, a);                 /* separate warp & fn statements */
    cscoreListPlay(cs, b);                            /* and send these to performance */
    a = cscoreListAppendStringEvent(cs, a, "s");       /* append a sect statement to note list */
}
```

```
cscoreListPlay(cs, a);                                /* play the note-list without interpretation */
for (ep = &a->e[1], nl = a->nevents; nl--; ) { /* now pulse-modifiy it */
    e = *ep++;
    if (e->op == 'i') {
        e->p[2] = pulse16[(int)(4. * e->p2orig)];
        e->p[3] = pulse16[(int)(4. * (e->p2orig + e->p3orig))] - e->p[2];
    }
}
cscoreListPlay(cs, a);                                /* now play modified list */
}
```

---

# Csbeats

*Csbeats* is an alternative score language that is aimed at specifying simple scores in standard western tunings and rhythms. *Csbeats* can be invoked via the CsScore component of a standard .csd score with *bin="csbeats"* or as stand-alone program which generates a standard numeric score.

As a stand-alone the program reads standard input and writes to standard output.

The *csbeats* language is very simple, having only 5 kinds of statement, and only one of them has any complexity. In general the introductory word for each statement type is case insensitive, so "QUIT", "quit", "QuIt"... are all the same. Comments can be introduced in either ANSI C89 format or C++ (that is either /\* ... \*/ or // to the end of line) or Csound's semi-colon.

- *QUIT*

Causes csbeats to exit. For flexibility the command *END* is also accepted for the identical action.

- *BEATS*=integer

Sets the number of beats per minute for the following score until the end or until it is reset. The default value is 60bpm. The token *BPS* is also acceptable instead of BEATS.

- *PERMEASURE*=integer

Sets the number of beats in a bar. The default value is 4.

- *BAR*

Start a new bar.

- *BAR* integer

Start the bar whose number is given.

- *i* integer attributes

Specified a note event for the numbered instrument. The attributes may be any of a pitch, duration or dynamic, or a positioning of the note to a beat or measure, and can be in any order.

Pitches are specified with a conventional note name (English form) in upper case optionally followed by a #, x (for double sharp), b (for flat) or bb (for double flat). A note of Z is a rest (think zzzz). All notes except rests must be followed by an octave number, with A4 being international A (440Hz). Pitches are passed to Csound in Hertz in the parameter p4, and are twelve tone equal temperament.

Durations are coded in lower case with the initial letter of the name for whole, half, quarter, eighth and sixteenth notes, or th for thirtysecondth notes. Except for w these can be moderated by appending as suffix:

- *d* or . Dotted note (half as long again)
- *dd* or .. Dotted note (three quarters as long again)

- *t* Triplet note (third notes in two)
- *t.* Dotted triplet note
- *q* Quintuplet (Five notes in four)
- *s* Septuplet (Seven notes in eight)

Durations can be added together by giving more than one duration. To make this more intuitive a + sign can be used instead of white space.

The dynamics are written in conventional notation, that is fff, ff, f, mf, mp, p, pp, ppp, pppp. These are passed to the instrument as p5 as 0 for fff, and one less dB for each step below. The default dynamic is fortissimo.

Additional parameters (p-fields) can be specified in an instrument statement by giving statements like *p6=42* which would set the p6 field to 42 until it is changed. The number must be 6 or greater as the first 5 fields are taken with fixed information. Each instrument number has its own additional parameters.

If any of these attributes is missing it carried forward from the previous note, with beat position being incremented to the end of the previous note.

In addition an event can be directed to a particular measure with an m attribute or a particular beat with a b.

The opening of Bach's Goldberg variation number 3 can be coded as:

```
; Bach - Goldberg Variations - Variato 3
; by Brian Baughn 3-14-05

## A Complete Example

Here is a simple example of the *csbeats* score generator. It uses the file *csbeats.csd* [examples/csbeats.csd].

### Example 1148. A simple example of csbeats.

See the sections *Real-time Audio* and *Command Line Flags* for more information on using command line flags.

# Appendix A. List of examples

## **Orchestra Syntax:Header.**

*0dbfs.csd* [examples/0dbfs.csd]  
*nchnls.csd* [examples/nchnls.csd]  
*nchnls\_i.csd* [examples/nchnls\_i.csd]  
*sr.csd* [examples/sr.csd]

## **Orchestra Syntax:Block Statements.**

*endin.csd* [examples/endin.csd]  
*endop.csd* [examples/endop.csd]  
*instr.csd* [examples/instr.csd]  
*opcode\_example.csd* [examples/opcode\_example.csd]

## **Orchestra Syntax:Macros.**

*define.csd* [examples/define.csd]  
*define\_args.csd* [examples/define\_args.csd]  
*define.csd* [examples/define.csd]  
*define\_args.csd* [examples/define\_args.csd]  
*include.csd* [examples/include.csd]

## **Signal Generators:Additive Synthesis/Resynthesis.**

*adsyn.csd* [examples/adsyn.csd]  
*adsynt.csd* [examples/adsynt.csd]  
*adsynt2.csd* [examples/adsynt2.csd]  
*hsboscil.csd* [examples/hsboscil.csd]  
*hsboscil\_midi.csd* [examples/hsboscil\_midi.csd]

## **Signal Generators:Basic Oscillators.**

*lfo.csd* [examples/lfo.csd]  
*oscbnk.csd* [examples/oscbnk.csd]  
*oscil.csd* [examples/oscil.csd]  
*oscil3.csd* [examples/oscil3.csd]

*oscili.csd* [examples/oscili.csd]  
*oscilikt.csd* [examples/oscilikt.csd]  
*osciliktp.csd* [examples/osciliktp.csd]  
*oscilikts.csd* [examples/oscilikts.csd]  
*osciln.csd* [examples/osciln.csd]  
*oscils.csd* [examples/oscils.csd]  
*poscil.csd* [examples/poscil.csd]  
*poscil3.csd* [examples/poscil3.csd]  
*poscil3-file.csd* [examples/poscil3-file.csd]  
*vibr.csd* [examples/vibr.csd]  
*vibrato.csd* [examples/vibrato.csd]

**Signal Generators:Dynamic Spectrum Oscillators.**

*buzz.csd* [examples/buzz.csd]  
*gbuzz.csd* [examples/gbuzz.csd]  
*mpulse.csd* [examples/mpulse.csd]  
*vco.csd* [examples/vco.csd]  
*vco2.csd* [examples/vco2.csd]  
*vco2ift.csd* [examples/vco2ift.csd]  
*vco2init.csd* [examples/vco2init.csd]

**Signal Generators:FM Synthesis.**

*crossfm.csd* [examples/crossfm.csd]  
*fmb3.csd* [examples/fmb3.csd]  
*fmbell.csd* [examples/fmbell.csd]  
*fmmetal.csd* [examples/fmmetal.csd]  
*fmpercfl.csd* [examples/fmpercfl.csd]  
*fmrhode.csd* [examples/fmrhode.csd]  
*fmvoice.csd* [examples/fmvoice.csd]  
*fmwurlie.csd* [examples/fmwurlie.csd]  
*foscil.csd* [examples/foscil.csd]  
*foscili.csd* [examples/foscili.csd]

---

**Signal Generators:Granular Synthesis.**

*diskgrain.csd* [examples/diskgrain.csd]  
*fof.csd* [examples/fof.csd]  
*fof2.csd* [examples/fof2.csd]  
*fof2-2.csd* [examples/fof2-2.csd]  
*fog.csd* [examples/fog.csd]  
*grain.csd* [examples/grain.csd]  
*grain2.csd* [examples/grain2.csd]  
*grain3.csd* [examples/grain3.csd]  
*granule.csd* [examples/granule.csd]  
*partikkel.csd* [examples/partikkel.csd]  
*partikkel-2.csd* [examples/partikkel-2.csd]  
*partikkelsync.csd* [examples/partikkelsync.csd]  
*sndwarp.csd* [examples/sndwarp.csd]  
*sndwarpst.csd* [examples/sndwarpst.csd]  
*syncgrain.csd* [examples/syncgrain.csd]  
*syncloop.csd* [examples/syncloop.csd]  
*vosim.csd* [examples/vosim.csd]

**Signal Generators:Hyper Vectorial Synthesis.**

*hvs1.csd* [examples/hvs1.csd]  
*hvs2.csd* [examples/hvs2.csd]  
*hvs2-2.csd* [examples/hvs2-2.csd]  
*hvs3.csd* [examples/hvs3.csd]

**Signal Generators:Linear and Exponential Generators.**

*cosseg.csd* [examples/cosseg.csd]  
*cossegb.csd* [examples/cossegb.csd]  
*cossegr.csd* [examples/cossegr.csd]  
*expcurve.csd* [examples/expcurve.csd]  
*expon.csd* [examples/expon.csd]

*expseg.csd* [examples/expseg.csd]  
*expsega.csd* [examples/expsega.csd]  
*expsegb.csd* [examples/expsegb.csd]  
*expsegba.csd* [examples/expsegba.csd]  
*expsegr.csd* [examples/expsegr.csd]  
*gainslider.csd* [examples/gainslider.csd]  
*jspline.csd* [examples/jspline.csd]  
*line.csd* [examples/line.csd]  
*linseg.csd* [examples/linseg.csd]  
*linsegb.csd* [examples/linsegb.csd]  
*linsegr.csd* [examples/linsegr.csd]  
*logcurve.csd* [examples/logcurve.csd]  
*loopseg.csd* [examples/loopseg.csd]  
*loopsegp.csd* [examples/loopsegp.csd]  
*looptseg.csd* [examples/looptseg.csd]  
*loopxseg.csd* [examples/loopxseg.csd]  
*lpshold.csd* [examples/lpshold.csd]  
*rspline.csd* [examples/rspline.csd]  
*scale.csd* [examples/scale.csd]  
*transeg.csd* [examples/transeg.csd]  
*transegb.csd* [examples/transegb.csd]  
*transegr.csd* [examples/transegr.csd]

**Signal Generators:Envelope Generators.**

*adsr.csd* [examples/adsr.csd]  
*envlpx.csd* [examples/envlpx.csd]  
*envlpxr.csd* [examples/envlpxr.csd]  
*linen.csd* [examples/linen.csd]  
*linenr.csd* [examples/linenr.csd]  
*madsr.csd* [examples/madsr.csd]  
*madsr-2.csd* [examples/madsr-2.csd]

---

*mxadsr.csd* [examples/mxadsr.csd]

*xadsr.csd* [examples/xadsr.csd]

**Signal Generators:Models and Emulations.**

*bamboo.csd* [examples/bamboo.csd]

*barmodel.csd* [examples/barmodel.csd]

*cabasa.csd* [examples/cabasa.csd]

*chuap.csd* [examples/chuap.csd]

*crunch.csd* [examples/crunch.csd]

*dripwater.csd* [examples/dripwater.csd]

*gendy.csd* [examples/gendy.csd]

*gendy-2.csd* [examples/gendy-2.csd]

*gendyc.csd* [examples/gendyc.csd]

*gendyx.csd* [examples/gendyx.csd]

*gendyx-2.csd* [examples/gendyx-2.csd]

*gogobel.csd* [examples/gogobel.csd]

*guiro.csd* [examples/guiro.csd]

*lorenz.csd* [examples/lorenz.csd]

*mandel.csd* [examples/mandel.csd]

*mandol.csd* [examples/mandol.csd]

*marimba.csd* [examples/marimba.csd]

*moog.csd* [examples/moog.csd]

*planet.csd* [examples/planet.csd]

*prepiano.csd* [examples/prepiano.csd]

*sandpaper.csd* [examples/sandpaper.csd]

*sekere.csd* [examples/sekere.csd]

*shaker.csd* [examples/shaker.csd]

*sleighbells.csd* [examples/sleighbells.csd]

*stix.csd* [examples/stix.csd]

*tambourine.csd* [examples/tambourine.csd]

*vibes.csd* [examples/vibes.csd]

*voice.csd* [examples/voice.csd]

**Signal Generators:Phasors.**

*phasor.csd* [examples/phasor.csd]

*phasorbnk.csd* [examples/phasorbnk.csd]

*syncphasor.csd* [examples/syncphasor.csd]

*syncphasor-CZresonance.csd* [examples/syncphasor-CZresonance.csd]

**Signal Generators:Random (Noise) Generators.**

*betarand.csd* [examples/betarand.csd]

# Appendix D. Formant Values

**Table D.1. alto “a”**

| Values    | f1  | f2   | f3   | f4   | f5   |
|-----------|-----|------|------|------|------|
| freq (Hz) | 800 | 1150 | 2800 | 3500 | 4950 |
| amp (dB)  | 0   | -4   | -20  | -36  | -60  |
| bw (Hz)   | 80  | 90   | 120  | 130  | 140  |

**Table D.2. alto “e”**

| Values    | f1  | f2   | f3   | f4   | f5   |
|-----------|-----|------|------|------|------|
| freq (Hz) | 400 | 1600 | 2700 | 3300 | 4950 |
| amp (dB)  | 0   | -24  | -30  | -35  | -60  |
| bw (Hz)   | 60  | 80   | 120  | 150  | 200  |

**Table D.3. alto “i”**

| Values    | f1  | f2   | f3   | f4   | f5   |
|-----------|-----|------|------|------|------|
| freq (Hz) | 350 | 1700 | 2700 | 3700 | 4950 |
| amp (dB)  | 0   | -20  | -30  | -36  | -60  |
| bw (Hz)   | 50  | 100  | 120  | 150  | 200  |

**Table D.4. alto “o”**

| Values    | f1  | f2  | f3   | f4   | f5   |
|-----------|-----|-----|------|------|------|
| freq (Hz) | 450 | 800 | 2830 | 3500 | 4950 |
| amp (dB)  | 0   | -9  | -16  | -28  | -55  |
| bw (Hz)   | 70  | 80  | 100  | 130  | 135  |

**Table D.5. alto “u”**

| Values    | f1  | f2  | f3   | f4   | f5   |
|-----------|-----|-----|------|------|------|
| freq (Hz) | 325 | 700 | 2530 | 3500 | 4950 |
| amp (dB)  | 0   | -12 | -30  | -40  | -64  |
| bw (Hz)   | 50  | 60  | 170  | 180  | 200  |

**Table D.6. bass “a”**

| Values    | f1  | f2   | f3   | f4   | f5   |
|-----------|-----|------|------|------|------|
| freq (Hz) | 600 | 1040 | 2250 | 2450 | 2750 |
| amp (dB)  | 0   | -7   | -9   | -9   | -20  |
| bw (Hz)   | 60  | 70   | 110  | 120  | 130  |

**Table D.7. bass “e”**

| Values    | f1  | f2   | f3   | f4   | f5   |
|-----------|-----|------|------|------|------|
| freq (Hz) | 400 | 1620 | 2400 | 2800 | 3100 |
| amp (dB)  | 0   | -12  | -9   | -12  | -18  |
| bw (Hz)   | 40  | 80   | 100  | 120  | 120  |

**Table D.8. bass “i”**

| Values    | f1  | f2   | f3   | f4   | f5   |
|-----------|-----|------|------|------|------|
| freq (Hz) | 250 | 1750 | 2600 | 3050 | 3340 |
| amp (dB)  | 0   | -30  | -16  | -22  | -28  |
| bw (Hz)   | 60  | 90   | 100  | 120  | 120  |

**Table D.9. bass “o”**

| Values    | f1  | f2  | f3   | f4   | f5   |
|-----------|-----|-----|------|------|------|
| freq (Hz) | 400 | 750 | 2400 | 2600 | 2900 |
| amp (dB)  | 0   | -11 | -21  | -20  | -40  |
| bw (Hz)   | 40  | 80  | 100  | 120  | 120  |

**Table D.10. bass “u”**

| Values    | f1  | f2  | f3   | f4   | f5   |
|-----------|-----|-----|------|------|------|
| freq (Hz) | 350 | 600 | 2400 | 2675 | 2950 |
| amp (dB)  | 0   | -20 | -32  | -28  | -36  |
| bw (Hz)   | 40  | 80  | 100  | 120  | 120  |

**Table D.11. countertenor “a”**

| Values    | f1  | f2   | f3   | f4   | f5   |
|-----------|-----|------|------|------|------|
| freq (Hz) | 660 | 1120 | 2750 | 3000 | 3350 |
| amp (dB)  | 0   | -6   | -23  | -24  | -38  |

# Appendix E. Modal Frequency Ratios

## Contributed by Scott Lindroth

John Bower, a student of Scott Lindroth, compiled this list of modal frequencies for various objects and materials. Some modes work better than others, and most need to be in a particular frequency range to sound plausible. Caveat emptor.

In general, wooden objects will not sound "wooden" unless a stochastic component is present in the sound (try banded waveguides). Nonetheless, some of the wooden objects make wonderful metallic instruments as well.

This ratios can be useful together with opcodes like *mode* or *streson*.

**Table E.1. Modal Frequency Ratios**

| Instrument             | Modal Frequency Ratios   |
|------------------------|--|
| Dahina tabla           | [1, 2.89, 4.95, 6.99, 8.01, 9.02]  |
| Bayan tabla            | [1, 2.0, 3.01, 4.01, 4.69, 5.63]   |
| Red Cedar wood plate   | [1, 1.47, 2.09, 2.56]  |
| Redwood wood plate     | [1, 1.47, 2.11, 2.57]  |
| Douglas Fir wood plate | [1, 1.42, 2.11, 2.47]  |
| uniform wooden bar     | [1, 2.572, 4.644, 6.984, 9.723, 12]  |
| uniform aluminum bar   | [1, 2.756, 5.423, 8.988, 13.448, 18.680]   |
| Xylophone              | [1, 3.932, 9.538, 16.688, 24.566, 31.147]  |

# Appendix F. Window Functions

Windowing functions are used for analysis, and as waveform envelopes, particularly in granular synthesis. Window functions are built in to some opcodes, but others require a function table to generate the window. *GEN20* is used for this purpose. The diagram of each window below, is accompanied by the *f* statement used to generate the it.

**Hamming.**

**Example F.1. Hamming window function statement**

```
f81    0    8192    20    1    1
```

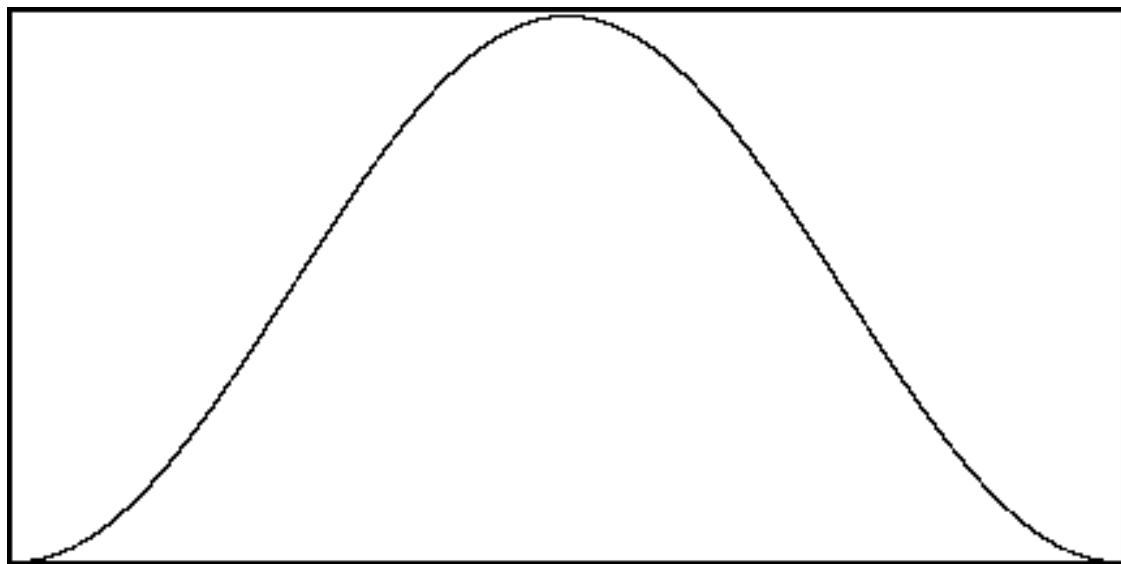

Hamming Window Function.

**Hanning.**

**Example F.2. Hanning window function statement**

```
f82    0    8192    20    2    1
```

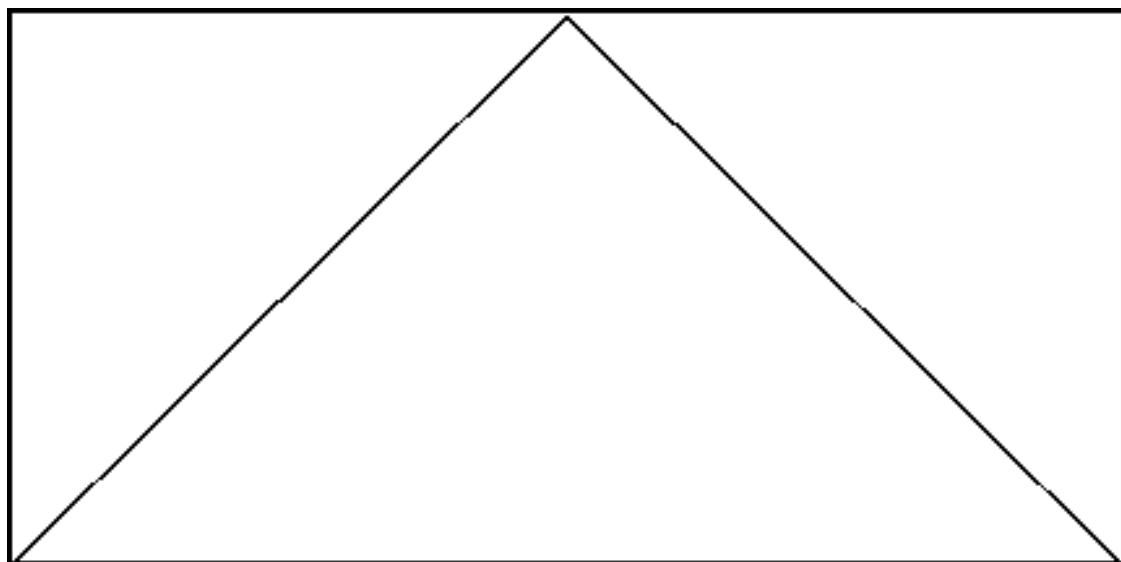

Hanning Window Function

**Bartlett.**

**Example F.3. Bartlett window function statement**

**f83 0 8192 20 3 1**

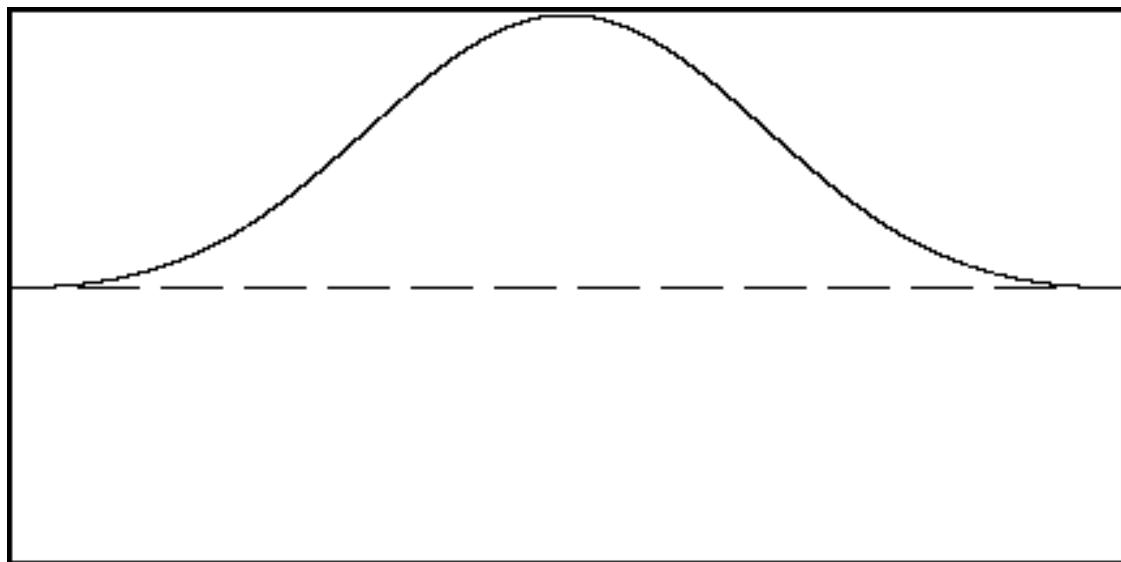

Bartlett Window Function

**Blackman.**

**Example F.4. Blackman window function statement**

**f84 0 8192 20 4 1**

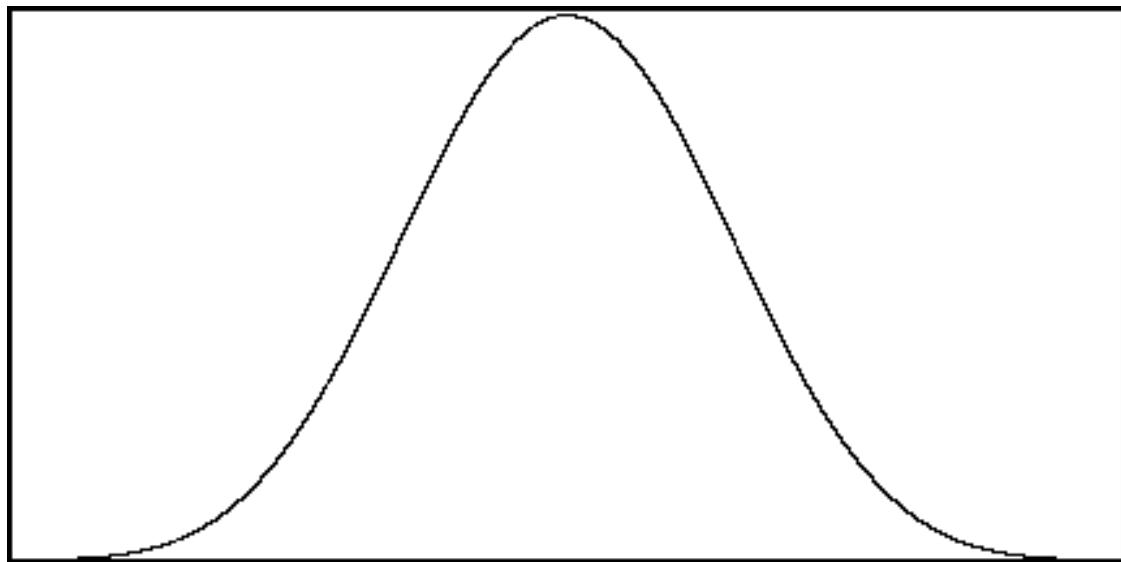

Blackman Window Function

**Blackman-Harris.**

**Example F.5. Blackman-Harris window function statement**

**f85 0 8192 20 5 1**

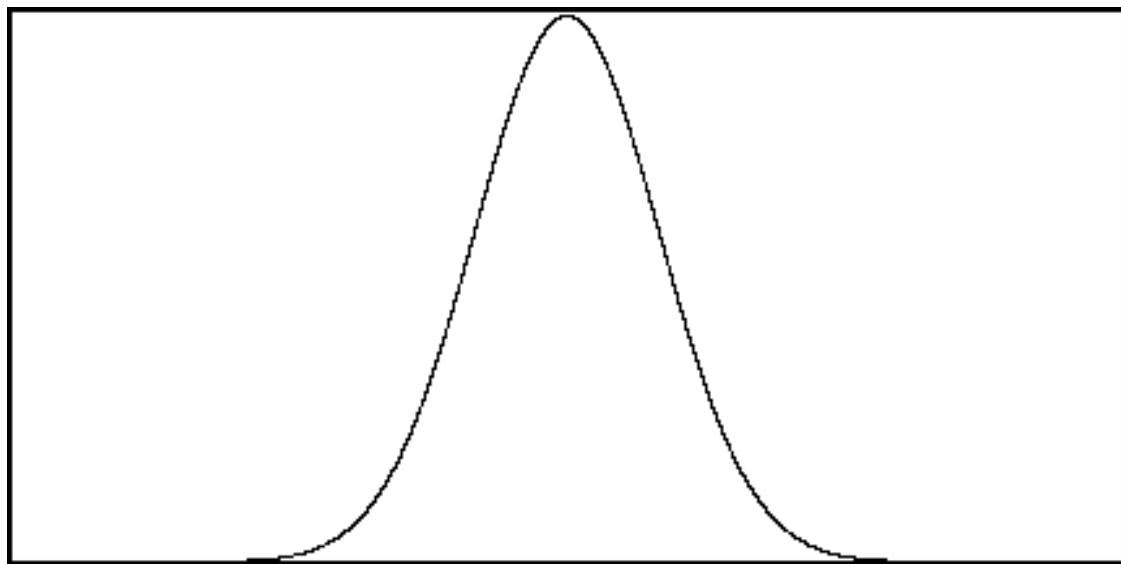

Blackman-Harris Window Function

**Gaussian.**

**Example F.6. Gaussian window function statement**

**f86 0 8192 20 6 1**

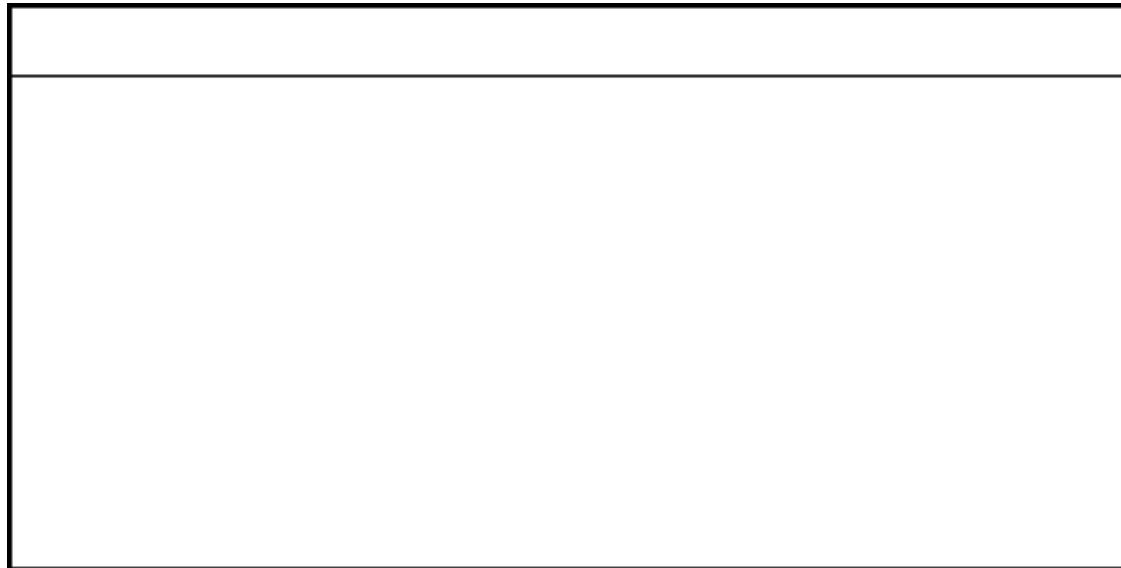

Gaussian Window Function

**Rectangle.**

**Example F.7. Rectangle window function statement**

```
f88    0    8192    -20    8    .1
```

*Note:* Vertical scale is exaggerated in this diagram.

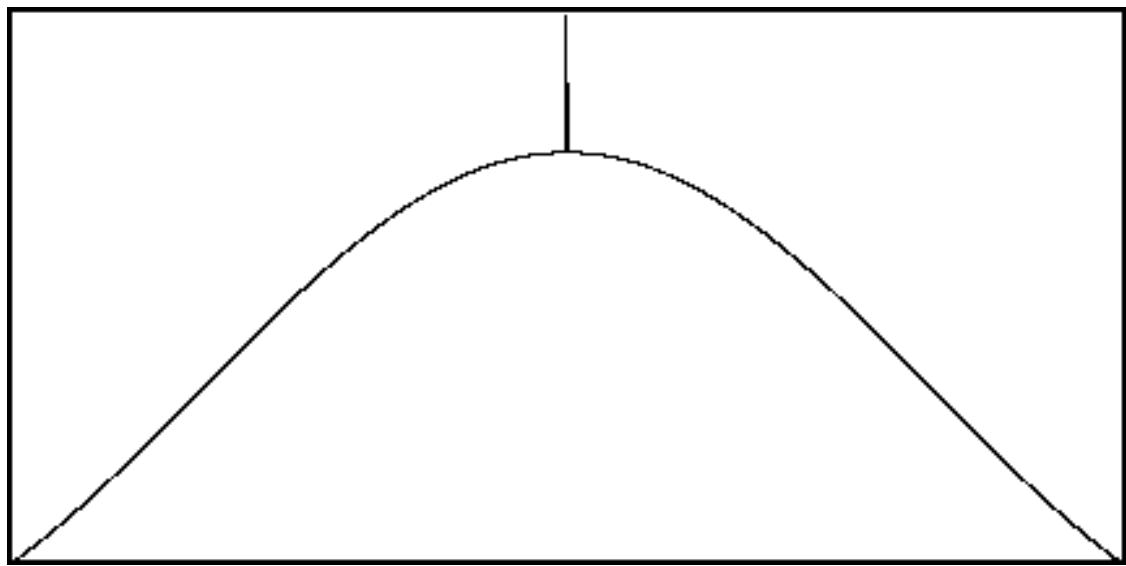

Rectangle Window Function

**Sync.**

**Example F.8. Sync window function statement**

**f89** 0 4096 -20 9 .75

# Appendix G. SoundFont2 File Format

Beginning with Csound Version 4.07, *Csound supports the SoundFont2 sample file format.* SoundFont2 (or SF2) is a widespread standard which allows encoding banks of wavetable-based sounds into a binary file. In order to understand the usage of these opcodes, the user must have some knowledge of the SF2 format, so a brief description of this format follows.

The SF2 format is made by generator and modulator objects. All current Csound opcodes regarding SF2 support the generator function only.

There are several levels of generators having a hierarchical structure. The most basic kind of generator object is a sample. Samples may or may not be be looped, and are associated with a MIDI note number, called the base-key. When a sample is associated with a range of MIDI note numbers, a range of velocities, a transposition (coarse and fine tuning), a scale tuning, and a level scaling factor, the sample and its associations make up a “split.” A set of splits, together with a name, make up an “instrument.” When an instrument is associated with a key range, a velocity range, a level scaling factor, and a transposition, the instrument and its associations make up a “layer.” A set of layers, together with a name, makes up a “preset.” Presets are normally the final sound-generating structures ready for the user. They generate sound according to the settings of their lower-level components.

Both sample data and structure data is embedded in the same SF2 binary file. A single SF2 file can contain up to a maximum of 128 banks of 128 preset programs, for a total of 16384 presets in one SF2 file. The maximum number of layers, instruments, splits, and samples is not defined, and probably is only limited by the computer's memory.

# Appendix H. Csound Double (64-bit) vs. Float (32-bit)

Csound can be built to use 64-bit DOUBLES internally to do processing versus regular Csound's 32-bit FLOATS. This larger resolution for processing internally yields a much "cleaner" sound but at the expense of extended processing time. Because it does require much longer to process, Csound compiled for doubles is typically used after a work is finished for a final production run. If you are using csound for realtime output, you should use the 32-bit (float) version, which provides faster output. For offline rendering, you can use either, but for the final master, the 64-bit version will produce higher quality output.

The actual resolution should be the same as for the type of the audio sample variable. For "float" Csound, that is a 32-bit, single-precision floating point number. It has 24 bits of precision in the mantissa. For "double" Csound, that is a 64-bit, double-precision floating point number in the mantissa. It has 52 bits of precision. For each decimal digit, there is between 3 and 4 bits. So, there are 7 digits of precision for "float" and 16 digits of precision for "double."

For each multiplication or division, depending on whether the operands are integers, rational numbers, repeating decimals, or irrational decimals, there may or may not be rounding error in the result. If there is rounding error, it is at most 1 bit of lost precision per operation (in addition to any rounding in the binary representation of rational or real numbers).

For float samples, if the signal stays within the mantissa, the signal to noise ratio is 6.02 times 24, or 144 dB. At worst, each operation will create 6.02 dB of additional noise due to rounding error. Our ears have an effective dynamic range of 120 to 130 dB, but we like our music compressed to a dynamic range of AT MOST 60 dB (and usually much less, say 20 dB). That gives us  $(144 - 60) / 6.02 =$  about 10 worst-case operations before we could possibly hear any degradation. In practice, we have several times that many operations before we hear any degradation or noise.

For double samples, if the signal stays within the mantissa, the signal to noise ratio is 6.02 times 52, or 313 dB. At worst, each operation will create 6.02 dB of additional noise due to rounding error. That gives us  $(313 - 60) / 6.02 =$  about 42, in practice several times that, of operations before there is any audible degradation or noise.

But if you trace the number of arithmetic operations in typical Csound instruments or other software synthesizers, the very complex instruments definitely are pushing into the range of audible degradation on good monitors with float, so it is no surprise that in some cases blindfold, controlled ABX testing confirms *occasional* audible differences between music synthesized with "float" Csound versus the same music synthesized with "double" Csound. Equally, it is no surprise that there are easily audible differences between digital and analog implementations of the same synthesis algorithms.

There is a good deal more "digital signal processing headroom" with double Csound, and therefore it should be used for all music rendered for critical listening. The float version should only be used where its speed advantage of about 15% is critical for real-time performance.

## Notes On Using Csound built for double precision

1. hetro, PVOC-EX analysis and pvanal files generated for 32-bit Csound (float) will work with 64-bit Csound (double precision).
2. All other analysis formats can be generated in a way for cross-use between 32 and 64 bit versions and big-endian and little-endian architectures, if the `-X` option is used in generation. The older format in csound5 is still generatable but is not machins independant.

# Glossary

## G

### Guard Point

A guard point is the last position on a function table. If the length is, say 1024, the table will have 1024+1 (1025) points: the extra point is the guard point.

In any case, for a 1024-point table, the first point is index 0 and the last 1023; index 1024 is not really used)

The reason for a guard-point is that some opcodes interpolate to obtain a table value, in which case, when the table index is say, 1023.5, we need the value of the 1024 pos in order to interpolate.

There are two ways of filling this point (writing the value that goes in it):

1. Default way: by copying the value of the 1st point in the table
2. Extended Guard-Point: extending the contour of the table (continuing to calculate the table for one extra point)

In general the first mode is used for wrap-around applications, such as an oscillator (which loops continuously reading the table). The second use is for one-shot readouts, such as envelopes, where the last point needs to be interpolated correctly following the table contour (we are not looping back to the beginning of the table)
